The SS edit descriptor causes the processor to *suppress* a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

SS

S Editing

The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the following form:

S

The S edit descriptor restores to the processor the discretion of producing plus characters on an optional basis.

Blank Editing

The blank editing descriptors control the interpretation of embedded and trailing blanks within numeric input fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input data transfer statement. For more information, see the BLANK specifier in OPEN statements.

See Also

Forms for Control Edit Descriptors

BN Editing

The BN edit descriptor causes the processor to *ignore* all embedded and trailing blanks in numeric input fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified. An all-blank field is treated as zero.

Examples

If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as ' 234'.

Consider the following code:

```
      READ (*, 100) n
100   FORMAT (BN, I6)
```

If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
   123
123
123   456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and *iolist*. Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

BZ Editing

The BZ edit descriptor causes the processor to *interpret* all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

BZ

Examples

The input field ' 23 4 ' is interpreted as ' 23040'. If ' 23 4' is entered, the formatter adds one blank to pad the input to the six-digit integer format (I6), but this extra space is ignored, and the input is interpreted as ' 2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

Round Editing

The round editing descriptors temporarily change the I/O rounding mode for a connection.

These forms of rounding correspond to the ROUND= specifier values UP, DOWN, ZERO, NEAREST, COMPATIBLE, and PROCESSOR DEFINED, respectively. Rounding conforms to the ISO/IEC 60559:2020 standard.

The I/O rounding mode affects the conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, EX, F, and G editing.

Each descriptor continues to be in effect until a different round editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors

RU Editing

The RU edit descriptor causes rounding to the smallest value that is greater than or equal to the original value. It takes the following form:

RU

RD Editing

The RD edit descriptor causes rounding to the largest representable value that is less than or equal to the original value. It takes the following form:

RD

RZ Editing

The RZ edit descriptor causes rounding to the value closest to the original value, but not greater in magnitude. It takes the following form:

RZ

RN Editing

The RN edit descriptor selects NEAREST rounding as specified by the ISO/IEC 60559:2020 standard. It takes the following form:

RN

RC Editing

The RC edit descriptor causes rounding to the closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero. It takes the following form:

RC

RP Editing

The RP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

RP

Decimal Editing

The decimal editing descriptors temporarily change the decimal edit mode for a connection.

These specifiers correspond to the DECIMAL= specifier values COMMA and POINT, respectively.

The decimal editing mode controls the representation of the decimal symbol during conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different decimal editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors

DC Editing

The DC edit descriptor changes the decimal editing mode for a connection to a decimal comma. It takes the following form:

DC

Note that during list-directed I/O, a semicolon is used as a value separator in place of a comma.

DP Editing

The DP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

DP

Scale-Factor Editing (P)

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

*k*P

The *k* is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of *k* is -128 to 127.

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify 0P.

Format reversion does not affect the scale factor. (For more information on format reversion, see Interaction Between Format Specifications and I/O Lists.)

Rules for Input Processing

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, EX, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by 10^{-k}. For example, a 2P scale factor multiplies an input value by .01, moving the decimal point two places to the left. A -2P scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The scale factor applies to decimal numbers without an exponent. For hexadecimal-significand numbers, the exponent is mandatory so the scale factor has no effect.

The following shows input using the P edit descriptor (the symbol ^ represents a non-printing blank character):

```
Format     Input          Value
3PE10.5    ^^^37.614^          .037614
3PE10.5    ^^37.614E2     3761.4
-3PE10.5   ^^^^37.614    37614.0
```

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

```
  (3P, I6, F6.3, E8.1)
  (I6, 3P, F6.3, E8.1)
  (I6, 3PF6.3, E8.1)
```

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

Rules for Output Processing

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by 10^k. This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by 10^k, and *k* is subtracted from the exponent. This changes the form of the data.

  A positive scale factor decreases the exponent; a negative scale factor increases the exponent.

  For a positive scale factor, *k* must be less than *d* + 2 or an output conversion error occurs.
- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).

  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.
- For EN, ES, and EX editing, the scale factor has no effect.

The following shows output using the P edit descriptor (the symbol ^ represents a non-printing blank character):

```
Format     Value         Output
1PE12.3    -270.139      ^^-2.701E+02
1P,E12.2   -270.139      ^^^-2.70E+02
-1PE12.2   -270.139      ^^^-0.03E+04
```

Examples

The following shows a FORMAT statement containing a scale factor:

```
     DIMENSION A(6)
     DO 10 I=1,6
10   A(I) = 25.
     WRITE (6, 100) A
100  FORMAT(' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:

```
   25.00  2500.00  2500.00
 2500.00  2500.00  2500.00
```

The following code uses scale-factor editing when reading:

```
      READ (*, 100) a, b, c, d
100   FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)

      WRITE (*, 200) a, b, c, d
200   FORMAT (4F11.3)
```

If the following data is entered:

```
12340000  12340000  12340000  12340000
   12.34     12.34     12.34     12.34
 12.34e0   12.34e0   12.34e0   12.34e0
 12.34e3   12.34e3   12.34e3   12.34e3
```

The program's output is:

```
   12.340      1.234      1.234   1234.000
   12.340      1.234      1.234   1234.000
   12.340     12.340     12.340     12.340
12340.000  12340.000  12340.000  12340.000
```

The next code shows scale-factor editing when writing:

```
      a = 12.34

      WRITE (*, 100) a, a, a, a, a, a
100   FORMAT (1X, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
     &        -2P, F9.4, E11.4E2)
```

This program's output is:

```
12.3400 0.1234E+02 123.4000 1.2340E+01   0.1234 0.0012E+04
```

Forms for Control Edit Descriptors

Slash Editing (/)

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

[r]/

The *r* is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of *r* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If *r* is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:

- When *n* consecutive slashes appear between two edit descriptors, *n* - 1 records are skipped on input, or *n* - 1 blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.
- When *n* consecutive slashes appear at the beginning or end of a format specification, *n* records are skipped or *n* blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```
    WRITE (6,99)
99  FORMAT ('1',T51,'HEADING LINE'//T51,'SUBHEADING LINE'//)
```

The following lines are written:

```
                 Column 50, top of page         |         HEADING LINE
(blank line)        SUBHEADING LINE
(blank line)
(blank line)
```

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

Examples

```
!     The following statements write spreadsheet column and row labels:
      WRITE (*, 100)
100   FORMAT ('   A     B     C     D     E'                          &
     &        /,' 1',/,' 2',/,' 3',/,' 4',/,' 5')
```

The above example generates the following output:

```
  A     B     C     D     E
1
2
3
4
5
```

See Also

Forms for Control Edit Descriptors

Colon Editing (:)

The colon edit descriptor terminates format control if there are no more items in the I/O list.

Examples

Suppose the following statements are specified:

```
     PRINT 1,3
     PRINT 2,13
1    FORMAT (' I=',I2,' J=',I2)
2    FORMAT (' K=',I2,:,' L=',I2)
```

The above code causes the following lines to be written (the symbol ^ represents a non-printing blank character):

```
I=^3^J=
K=13
```

The following shows another example:

```
 !     The following example writes a= 3.20 b= .99
       REAL a, b, c, d
       DATA a /3.2/, b /.9871515/
       WRITE (*, 100) a, b
 100   FORMAT (' a=', F5.2, :, ' b=', F5.2, :, &
      &        ' c=', F5.2, :, ' d=', F5.2)
       END
```

See Also

Forms for Control Edit Descriptors

Dollar-Sign ($) and Backslash (\ ) Editing

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).

For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

```
       TYPE 100
100    FORMAT (' ENTER RADIUS VALUE ',$)
       ACCEPT 200, RADIUS
200    FORMAT (F6.2)
```

The following prompt is displayed:

```
  ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
  ENTER RADIUS VALUE    12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

```
     CHARACTER(20) MYNAME
     WRITE (*,9000)
9000 FORMAT ('Please type your name:',\)
```

```
     READ  (*,9001) MYNAME
9001 FORMAT (A20)
     WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

The following shows the same example using Fortran standard constructs:

```
     CHARACTER(20) MYNAME
     WRITE (*,9000, ADVANCE='NO')
9000 FORMAT ('Please type your name:')
     READ  (*,9001) MYNAME
9001 FORMAT (A20)
     WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

See Also

Forms for Control Edit Descriptors

Character Count Editing (Q)

The character count edit descriptor returns the remaining number of characters in the current input record.

The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```
      READ (4,1000) XRAY, KK, NCHRS, (ICHR(I), I=1,NCHRS)
1000  FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)

If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

Examples

Consider the following:

```
       CHARACTER ICHAR(80)
       READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
 1000  FORMAT (E15.7, I4, Q, 80A1)
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```

The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```
      CHARACTER STR(80)
      INTEGER LENGTH
      REAL REAL1
      OPEN (UNIT = 10, FILE = 'Q.DAT')
100   FORMAT (F8.3, Q, 80A1)
      READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
      WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
     & I= 1, LENGTH)
      END
```

The output on the screen is:

```
1234.567  13  Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abcdefg
abcd
```

Consider it is then READ with the following statements:

```
      OPEN (10, FILE = "Q.DAT")
      READ(10, 100) LENGTH
100   FORMAT(Q)
      WRITE(*,'(I2)') LENGTH
      READ(10, 100) LENGTH
      WRITE(*,'(I2)') LENGTH
      END
```

The output to the screen would be:

```
7
4
```

Forms for Control Edit Descriptors

Character String Edit Descriptors

Character string edit descriptors control the output of character strings. The character string edit descriptors are the character constant and H edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification or a * indicating an unlimited repeat count.

See Also

Nested and Group Repeat Specifications

Character Constant Editing

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

'*string*'

"*string*"

The *string* is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.

To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes ('') in the format specification; for example:

```
50   FORMAT ('TODAY''S^DATE^IS:^',I2,'/',I2,'/',I2)
```

Note that the symbol ^ represents a non-printing blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks ("") in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.

Examples

Consider the following '(3I5)' format in the WRITE statement:

```
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```
      WRITE (10, 100) I1, I2, I3
100   FORMAT( 3I5)
```

The following shows another example:

```
!     These WRITE statements both output ABC'DEF
!     (The leading blank is a carriage-control character).
      WRITE (*, 970)
970   FORMAT (' ABC''DEF')
      WRITE (*, '('' ABC''''DEF'')')
!     The following WRITE also outputs ABC'DEF. No carriage-
!     control character is necessary for list-directed I/O.
      WRITE (*,*) 'ABC''DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant `ABC'DEF` requires no special treatment:

```
WRITE (*,*) "ABC'DEF"
```

Character constants

Format Specifications

H Editing

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

An H edit descriptor has the form of a Hollerith constant, as follows:

*n*H*string*

n	Is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in *string* (including blanks and tabs). The range of *n* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.
string	Is a string of printable ASCII characters.

On input, the H edit descriptor transfers *n* characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters. If the edit descriptor appears in a FORMAT statement, the replaced characters are preserved for future uses of that FORMAT statement; otherwise, the replacement is discarded.

On output, the H edit descriptor causes *n* characters following the letter H to be output to an external record.

Examples

```
!     These WRITE statements both print "Don't misspell 'Hollerith'"
!     (The leading blanks are carriage-control characters).
!     Hollerith formatting does not require you to embed additional
!     single quotation marks as shown in the second example.
!
      WRITE (*, 960)
960   FORMAT (27H Don't misspell 'Hollerith')
      WRITE (*, 961)
961   FORMAT (' Don''t misspell ''Hollerith''')
```

Deleted and Obsolescent Language Features
Format Specifications

Nested and Group Repeat Specifications

Format specifications can include nested format specifications enclosed in parentheses; for example:

```
15    FORMAT (E7.2,I8,I2,(A5,I6))
35    FORMAT (A6,(L8(3I2)),A)
```

A group repeat specification can precede a nested group of edit descriptors; it can be an unsigned integer literal constant, a variable format expression, or * to indicate an unlimited repeat count. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

```
50    FORMAT (I8,I8,F8.3,E15.7,F8.3,E15.7,F8.3,E15.7,I5,I5)
50    FORMAT (2I8,3(F8.3,E15.7),2I5)
```

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

```
76    FORMAT ('MONTHLY',3('TOTAL'))
100   FORMAT (I8,4(T7),A4)
```

Each of the following can be used to read data at the end of an input record into N elements of array A:

```
    read (10,'(<N>F8.2)') A(1:N)  ! Variable format expression
    read(10,'(*(F8.2))') A(1:N)   ! Unlimited repeat count
```

Interaction Between Format Specifications and I/O Lists for details on group repeat specifications and format reversion

Variable Format Expressions

A variable format expression is a numeric expression enclosed in angle brackets (< >) that can be used in a FORMAT statement or in a character format specification.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.

Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications that are not character constant expressions.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

Examples

Consider the following statement:

```
  FORMAT (I<J+1>)
```

When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```
      DIMENSION A(5)
      DATA A/1.,2.,3.,4.,5./

      DO 10 I=1,10
      WRITE (6,100) I
100   FORMAT (I<MAX(I,5)>)
10    CONTINUE

      DO 20 I=1,5
      WRITE (6,101) (A(I), J=1,I)
101   FORMAT (<I>F10.<I-1>)
20    CONTINUE
      END
```

On execution, these statements produce the following output:

```
    1
    2
    3
    4
    5
     6
      7
       8
        9
        10
        1.
       2.0        2.0
      3.00       3.00     3.00
     4.000      4.000    4.000     4.000
    5.0000    5.0000    5.0000    5.0000    5.0000
```

The following shows another example:

```
       WRITE(6,20) INT1
20     FORMAT(I<MAX(20,5)>)

       WRITE(6,FMT=30) REAL2(10), REAL3
30     FORMAT(<J+K>X, <2*M>F8.3)
```

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

```
       INTEGER width, value
       width=2
       READ (*,10) width, value
10     FORMAT(I1, I <width>)
       PRINT *, value
       END
```

When given input 3123, the program will print 123 and not 12.

Interaction Between Format Specifications and I/O Lists for details on the synchronization of I/O lists with formats

Print Formatted Records

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

Printing control characters are a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following table lists the valid control characters for printing:

Control Characters for Printing

Character	Meaning	Effect
+	Overprinting	Outputs the record (at the current position in the current line) and a carriage return.
-	One line feed	Outputs the record (at the beginning of the following line) and a carriage return.
0	Two line feeds	Outputs the record (after skipping a line) and a carriage return.
1	Next page	Outputs the record (at the beginning of a new page) and a carriage return.
$	Prompting	Outputs the record (at the beginning of the following line), but no carriage return.
ASCII NUL[1]	Overprinting with no advance	Outputs the record (at the current position in the current line), but no carriage return.

[1] Specify as CHAR(0).

Any other character is interpreted as a blank and is deleted from the print line. If you do not specify a control character for printing, the first character of the record is not printed.

Interaction Between Format Specifications and I/O Lists

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, EX, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, EX, D, or G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.

When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).

Examples

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

```
001 0101 0102 0103 0104 0105
002 0201 0202 0203 0204 0205
003 0301 0302 0303 0304 0305
004 0401 0402 0403 0404 0405
005 0501 0502 0503 0504 0505
006 0601 0602 0603 0604 0605
007 0701 0702 0703 0704 0705
008 0801 0802 0803 0804 0805
009 0901 0902 0903 0904 0905
010 1001 1002 1003 1004 1005
```

The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

```
      INTEGER I, J, A(2,5), B(2)
      OPEN (unit=2, access='sequential', file='FOR002.DAT')

      READ (2,100) (B(I), (A(I,J), J=1,5),I=1,2) 1

100   FORMAT (2 (I3, X, 5(I4,X), /) ) 2

      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 3

999   FORMAT (' B is ', 2(I3, X), ';  A is', /
     1       (' ', 5 (I4, X)) )

      READ (2,200) (B(I), (A(I,J), J=1,5),I=1,2) 4

200   FORMAT (2 (I3, X, 5(I4,X), :/) )
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 5

      READ (2,300) (B(I), (A(I,J), J=1,5),I=1,2) 6

300   FORMAT ( (I3, X, 5(I4,X)) )

      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 7

      READ (2,400) (B(I), (A(I,J), J=1,5),I=1,2) 8

400   FORMAT ( I3, X, 5(I4,X) )

      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 9

      END
```

1 This statement reads B(1); then A(1,1) through A(1,5); then B(2) and A(2,1) through A(2,5).

The first record read (starting with 001) starts the processing of the I/O list.

2 There are two records, each in the format I3, X, 5(I4, X). The slash (/) forces the reading of the second record after A(1,5) is processed. It also forces the reading of the third record after A(2,5) is processed; no data is taken from that record.

3 This statement produces the following output:

```
B is   1   2 ;  A is 101  102  103  104  105 201  202  203  204  205
```

4 This statement reads the record starting with 004. The slash (/) forces the reading of the next record after A(1,5) is processed. The colon (:) stops the reading after A(2,5) is processed, but before the slash (/) forces another read.

5 This statement produces the following output:

```
B is   4   5 ;  A is 401  402  403  404  405 501  502  503  504  505
```

6 This statement reads the record starting with 006. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I3.

7 This statement produces the following output:

```
B is   6   7 ;  A is 601  602  603  604  605 701  702  703  704  705
```

8 This statement reads the record starting with 008. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I4.

9 This statement produces the following output:

```
B is   8  90 ;  A is 801  802  803  804  805 9010 9020 9030 9040 100
```

The record 009 0901 0902 0903 0904 0905 is processed with I4 as "009 " for B(2), which is 90. X skips the next "0". Then "901 " is processed for A(2,1), which is 9010, "902 " for A(2,2), "903 " for A(2,3), and "904 " for A(2,4). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the I4, so "010 " is read for A(2,5), which is 100.

File Operation I/O Statements

The following are file connection, inquiry, and positioning I/O statements:

- BACKSPACE

  Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing.
- CLOSE

  Terminates the connection between a logical unit and a file or device.
- DELETE

  Deletes a record from a relative file.
- ENDFILE

  Writes an end-of-file record to a sequential file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.
- FLUSH

  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.
- INQUIRE

  Requests information on the status of specified properties of a file or logical unit. For more information on specifiers you can use in INQUIRE statements, see INQUIRE Statement Specifiers.
- OPEN

  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations. For more information on specifiers you can use in OPEN statements, see OPEN Statement Specifiers.
- REWIND

  Positions a sequential or direct access file at the beginning of the file (the initial point).
- WAIT

  Performs a wait operation for a specified pending asynchronous data transfer operation.

The following table summarizes I/O statement specifiers:

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
ACCESS=*access*	'SEQUENTIAL', 'DIRECT', 'STREAM', or 'APPEND'	Specifies the method of file access.	INQUIRE, OPEN
ACTION=*permission*	'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')	Specifies file I/O mode.	INQUIRE, OPEN
ADVANCE=*c-expr*	'NO' or 'YES' (default is 'YES')	Specifies formatted sequential data input as advancing, or non-advancing.	READ
ASSOCIATEVARIABLE=*var*	Integer variable	Specifies a variable to be updated to reflect the record number of the next sequential record in the file.	OPEN
ASYNCHRONOUS=*asynch*	'YES' or 'NO' (default is 'NO')	Specifies whether or not the I/O is done asynchronously	INQUIRE, OPEN
BINARY=*bin*	'NO' or 'YES'	Returns whether file format is binary.	INQUIRE
BLANK=*blank_control*	'NULL' or 'ZERO' (default is 'NULL')	Specifies whether blanks are ignored in numeric fields or interpreted as zeros.	INQUIRE, OPEN
BLOCKSIZE=*blocksize*	Positive integer variable or expression	Specifies or returns the internal buffer size used in I/O.	INQUIRE, OPEN
BUFFERCOUNT=*bc*	Numeric expression	Specifies the number of buffers to be associated with the unit for multibuffered I/O.	OPEN
BUFFERED=*bf*	'YES' or 'NO' (default is 'NO')	Specifies runtime library behavior following WRITE operations.	INQUIRE, OPEN
CARRIAGECONTROL=*control*	'FORTRAN', 'LIST', or 'NONE'	Specifies carriage control processing.	INQUIRE, OPEN
CONVERT=*form*	'LITTLE_ENDIAN', 'BIG_ENDIAN', 'CRAY', 'FDX', 'FGX', 'IBM', 'VAXD', 'VAXG', or 'NATIVE' (default is 'NATIVE')	Specifies a numeric format for unformatted data.	INQUIRE, OPEN
DEFAULTFILE=*var*	Character expression	Specifies a default file pathname string.	INQUIRE, OPEN

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
DELIM=*delimiter*	'APOSTROPHE', 'QUOTE' or 'NONE' (default is 'NONE')	Specifies the delimiting character for list-directed or namelist data.	INQUIRE, OPEN
DIRECT=*dir*	'NO' or 'YES'	Returns whether file is connected for direct access.	INQUIRE
DISPOSE=*dis* (or DISP=*dis*)	'KEEP', 'SAVE', 'DELETE', 'PRINT', 'PRINT/DELETE', 'SUBMIT', or 'SUBMIT/DELETE' (default is 'DELETE' for scratch files; 'KEEP' for all other files)	Specifies the status of a file after the unit is closed.	OPEN, CLOSE
formatlist	Character variable or expression	Lists edit descriptors. Used in FORMAT statements and format specifiers (the FMT=*formatspec* option) to describe the format of data.	FORMAT, PRINT, READ, WRITE
END=*endlabel*	Integer between 1 and 99999	When an end of file is encountered, transfers control to the statement whose label is specified.	READ
EOR=*eorlabel*	Integer between 1 and 99999	When an end of record is encountered, transfers to the statement whose label is specified.	READ
ERR=*errlabel*	Integer between 1 and 99999	Specifies the label of an executable statement where execution is transferred after an I/O error.	All except PRINT
EXIST=*ex*	.TRUE. or .FALSE.	Returns whether a file exists and can be opened.	INQUIRE
FILE=*file*(or NAME=*name*)	Character variable or expression. Length and format of the name are determined by the operating system	Specifies the name of a file	INQUIRE, OPEN
[FMT=]*formatspec*	Character variable or expression	Specifies an *editlist* to use to format data.	PRINT, READ, WRITE
FORM=*form*	'FORMATTED', 'UNFORMATTED', or 'BINARY'	Specifies a file's format.	INQUIRE, OPEN

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
FORMATTED=*fmt*	'NO' or 'YES'	Returns whether a file is connected for formatted data transfer.	INQUIRE
IOFOCUS=*iof*	.TRUE. or .FALSE. (default is .TRUE. unless unit '*' is specified)	Specifies whether a unit is the active window in a QuickWin application.	INQUIRE, OPEN
iolist	List of variables of any type, character expression, or NAMELIST	Specifies items to be input or output.	PRINT, READ, WRITE
IOSTAT=*iostat*	Integer variable	Specifies a variable whose value indicates whether an I/O error has occurred.	All except PRINT
MAXREC=*var*	Numeric expression	Specifies the maximum number of records that can be transferred to or from a direct access file.	OPEN
MODE=*permission*	'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')	Same as ACTION.	INQUIRE, OPEN
NAMED=*var*	.TRUE. or .FALSE.	Returns whether a file is named.	INQUIRE
NEWUNIT=*u-var*	Scalar integer variable	Is assigned an unused unit number that is automatically chosen. It is always a negative integer.	OPEN
NEXTREC=*nr*	Integer variable	Returns where the next record can be read or written in a file.	INQUIRE
[NML=]*nmlspec*	Namelist name	Specifies a *namelist* group to be input or output.	PRINT, READ, WRITE
NUMBER=*num*	Integer variable	Returns the number of the unit connected to a file.	INQUIRE
OPENED=*od*	.TRUE. or .FALSE.	Returns whether a file is connected.	INQUIRE
ORGANIZATION=*org*	'SEQUENTIAL' or 'RELATIVE' (default is 'SEQUENTIAL')	Specifies the internal organization of a file.	INQUIRE, OPEN
PAD=*pad_switch*	'YES' or 'NO' (default is 'YES')	Specifies whether an input record is padded with blanks when the input list or format	INQUIRE, OPEN

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
		requires more data than the record holds, or whether the input record is required to contain the data indicated.	
POS=*pos*	Positive integer	Specifies the file storage unit position in a stream file.	INQUIRE, READ, WRITE
POSITION=*file_pos*	'ASIS', 'REWIND' or 'APPEND' (default is 'ASIS')	Specifies position in a file.	INQUIRE, OPEN
READ=*rd*	'NO' or 'YES'	Returns whether a file can be read.	INQUIRE
READONLY		Specifies that only READ statements can refer to this connection.	OPEN
READWRITE=*rdwr*	'NO' or 'YES'	Returns whether a file can be both read and written to.	INQUIRE
REC=*rec*	Positive integer variable or expression	Specifies the first (or only) record of a file to be read from, or written to.	READ, WRITE
RECL=*length*(or RECORDSIZE=*length*)	Positive integer variable or expression	Specifies the record length in direct access files, or the maximum record length in sequential files.	INQUIRE, OPEN
RECORDTYPE=*typ*	'FIXED', 'VARIABLE', 'SEGMENTED', 'STREAM', 'STREAM_LF', or 'STREAM_CR'	Specifies the type of records in a file.	INQUIRE, OPEN
SEQUENTIAL=*seq*	'NO' or 'YES'	Returns whether file is connected for sequential access.	INQUIRE
SHARE=*share*	'COMPAT', 'DENYNONE', 'DENYWR', 'DENYRD', or 'DENYRW' (default is 'DENYNONE')	Controls how other processes can simultaneously access a file on networked systems.	INQUIRE, OPEN
SHARED		Specifies that a file is connected for shared access by more than one program executing simultaneously.	OPEN

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
SIZE=*size*	Integer variable	Returns the number of characters read in a nonadvancing READ before an end-of-record condition occurred.	READ
STATUS=*status*(or TYPE=*status*)	'OLD', 'NEW', 'UNKNOWN' or 'SCRATCH' (default is 'UNKNOWN')	Specifies the status of a file on opening and/or closing.	CLOSE, OPEN
TITLE=*name*	Character expression	Specifies the name of a child window in a QuickWin application.	OPEN
UNFORMATTED=*unf*	'NO' or 'YES'	Returns whether a file is connected for unformatted data transfer.	INQUIRE
[UNIT=]*unitspec*	Integer variable or expression	Specifies the unit to which a file is connected.	All except PRINT
USEROPEN=*fname*	Name of a user-written function	Specifies an external function that controls the opening of a file.	OPEN
WRITE=*rd*	'NO' or 'YES'	Returns whether a file can be written to.	INQUIRE

INQUIRE Statement Specifiers

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see INQUIRE.

The following sections describe the INQUIRE statement specifiers.

See Also

UNIT control specifier
ERR control specifier
ID control specifier
IOMSG control specifier
IOSTAT control specifier
RECL specifier in OPEN statements
FILE specifier in OPEN statements
DEFAULTFILE specifier in OPEN statements

INQUIRE: ACCESS Specifier

The ACCESS specifier asks how a file is connected. It takes the following form:

ACCESS = *acc*

acc Is a scalar default character variable that is assigned one of the following values:

'SEQUENTIAL'	If the file is connected for sequential access
'STREAM'	If the file is connected for stream access
'DIRECT'	If the file is connected for direct access
'UNDEFINED'	If the file is not connected

INQUIRE: ACTION Specifier

The ACTION specifier asks which I/O operations are allowed for a file. It takes the following form:

ACTION = *act*

act Is a scalar default character variable that is assigned one of the following values:

'READ'	If the file is connected for input only
'WRITE'	If the file is connected for output only
'READWRITE'	If the file is connected for both input and output
'UNDEFINED'	If the file is not connected

INQUIRE: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:

ASYNCHRONOUS = *asyn*

asyn Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit is connected and asynchronous input/output is not in effect.
'YES'	If the file or unit is connected and asynchronous input/output is in effect.
'UNKNOWN'	If the file or unit is not connected.

INQUIRE: BINARY Specifier

The BINARY specifier asks whether a file is connected to a binary file. This specifier is only available for Windows. It takes the following form:

BINARY = *bin*

bin Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected to a binary file
'NO'	If the file is connected to a nonbinary file
'UNKNOWN'	If the file is not connected

INQUIRE: BLANK Specifier

The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:

BLANK = *blnk*

blnk Is a scalar default character variable that is assigned one of the following values:

'NULL'	If null blank control is in effect for the file
'ZERO'	If zero blank control is in effect for the file
'UNDEFINED'	If the file is not connected, or it is not connected for formatted data transfer

INQUIRE: BLOCKSIZE Specifier

The BLOCKSIZE specifier asks about the physical I/O transfer size. It takes the following form:

BLOCKSIZE = *bks*

bks Is a scalar integer variable.

The *bks* is assigned the current size of the physical I/O transfer. If the unit or file is not connected, the value assigned is zero.

INQUIRE: BUFFERED Specifier

The BUFFERED specifier asks whether runtime buffering is in effect. It takes the following form:

BUFFERED = *bf*

bf Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit is connected and buffering is not in effect.
'YES'	If the file or unit is connected and buffering is in effect.
'UNKNOWN'	If the file or unit is not connected.

INQUIRE: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

CARRIAGECONTROL = *cc*

cc Is a scalar default character variable that is assigned one of the following values:

'FORTRAN'	If the file is connected with Fortran carriage control in effect
'LIST'	If the file is connected with implied carriage control in effect
'NONE'	If the file is connected with no carriage control in effect
'UNKNOWN'	If the file is not connected

INQUIRE: CONVERT Specifier

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

CONVERT = *fm*

fm Is a scalar default character variable that is assigned one of the following values:

'LITTLE_ENDIAN'	If the file is connected with little endian integer and IEEE* floating-point data conversion in effect
'BIG_ENDIAN'	If the file is connected with big endian integer and IEEE floating-point data conversion in effect
'CRAY'	If the file is connected with big endian integer and CRAY* floating-point data conversion in effect
'FDX'	If the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE binary128 data conversion in effect
'FGX'	If the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE binary128 data conversion in effect
'IBM'	If the file is connected with big endian integer and IBM* System \370 floating-point data conversion in effect

'VAXD'	If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect
'VAXG'	If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect
'NATIVE'	If the file is connected with no data conversion in effect
'UNKNOWN'	If the file or unit is not connected for unformatted data transfer

INQUIRE: DECIMAL Specifier

The DECIMAL specifier asks which decimal editing mode is in effect for a file connection. It takes the following form:

DECIMAL = *dmode*

dmode Is a scalar default character variable that is assigned one of the following values:

'COMMA'	If a decimal comma is used during decimal editing mode.
'POINT'	If a decimal point is used during decimal editing mode.
'UNDEFINED'	If there is no connection or if the connection is not for formatted I/O.

INQUIRE: DELIM Specifier

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:

DELIM = *del*

del Is a scalar default character variable that is assigned one of the following values:

'APOSTROPHE'	If apostrophes are used to delimit character constants in list-directed and namelist output
'QUOTE'	If quotation marks are used to delimit character constants in list-directed and namelist output
'NONE'	If no delimiters are used
'UNDEFINED'	If the file is not connected, or is not connected for formatted data transfer

INQUIRE: DIRECT Specifier

The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

DIRECT = *dir*

dir Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for direct access
'NO'	If the file is not connected for direct access
'UNKNOWN'	If the file is not connected

INQUIRE: ENCODING Specifier

The ENCODING specifier asks what type of encoding is in effect for a file. It takes the following form:

ENCODING = *enc*

enc Is a scalar default character expression that is assigned one of the following values:

'UTF-8'	If the file is connected with UTF-8 encoding in effect.
'UNDEFINED'	If the file is connected for unformatted I/O.
'UNKNOWN'	If the processor is unable to determine the encoding form of the file.

INQUIRE: EXIST Specifier

The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

EXIST = *ex*

ex Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified file exists and can be opened, or if the specified unit exists
.FALSE.	If the specified file or unit does not exist or if the file exists but cannot be opened

The unit exists if it is a number in the range allowed by the processor.

INQUIRE: FORM Specifier

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (Windows) data transfer. It takes the following form:

FORM = *fm*

fm Is a scalar default character variable that is assigned one of the following values:

'FORMATTED'	If the file is connected for formatted data transfer
'UNFORMATTED'	If the file is connected for unformatted data transfer
'BINARY'	If the file is connected for binary data transfer
'UNDEFINED'	If the file is not connected

INQUIRE: FORMATTED Specifier

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

FORMATTED = *fmt*

fmt Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for formatted data transfer
'NO'	If the file is not connected for formatted data transfer
'UNKNOWN'	If the processor cannot determine whether the file is connected for formatted data transfer

INQUIRE: IOFOCUS Specifier

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. This specifier is only available for Windows. It takes the following form:

IOFOCUS = *iof*

iof Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified unit is the active window in a QuickWin application
.FALSE.	If the specified unit is not the active window in a QuickWin application

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

INQUIRE: MODE Specifier

MODE is a nonstandard synonym for ACTION.

INQUIRE: NAME Specifier

The NAME specifier returns the name of a file. It takes the following form:

NAME = *nme*

nme

Is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, *nme* is undefined.

The value assigned to *nme* is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of *nme* is too small to contain the entire value.)

NOTE
The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

See Also

The appropriate manual in your operating system documentation set for details on the maximum size of file pathnames

INQUIRE: NAMED Specifier

The NAMED specifier asks whether a file is named. It takes the following form:

NAMED = *nmd*

nmd

Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the file has a name
.FALSE.	If the file does not have a name

INQUIRE: NEXTREC Specifier

The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:

NEXTREC = *nr*

nr

Is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record (r) was previously read or written, the value assigned is r + 1.
- If no record has been read or written, the value assigned is 1.
- If there are pending asynchronous data transfer operations for the specified file, the value assigned is computed as if all pending data transfers have already completed.
- If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.

- If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

INQUIRE: NUMBER Specifier

The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:

NUMBER = *num*

num — Is a scalar integer variable.

The *num* is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

INQUIRE: OPENED Specifier

The OPENED specifier asks whether a file is connected. It takes the following form:

OPENED = *od*

od — Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified file or unit is connected
.FALSE.	If the specified file or unit is not connected

INQUIRE: ORGANIZATION Specifier

The ORGANIZATION specifier asks how the file is organized. It takes the following form:

ORGANIZATION = *org*

org — Is a scalar default character variable that is assigned one of the following values:

'SEQUENTIAL'	If the file is a sequential file
'RELATIVE'	If the file is a relative file
'UNKNOWN'	If the processor cannot determine the file's organization

INQUIRE: PAD Specifier

The PAD specifier asks whether blank padding was specified for the file. It takes the following form:

PAD = *pd*

pd — Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit was connected with PAD='NO'

'YES'	If the file or unit is not connected, or it was connected with PAD='YES'

INQUIRE: PENDING Specifier

The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:

PENDING = *pnd*

pnd	Is a scalar default logical variable that is assigned the value .TRUE. or .FALSE..

The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable *pnd* is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable *pnd* is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.
- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable *pnd* is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable *pnd* is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.

See Also

ID Specifier

Example in INQUIRE Statement

INQUIRE: POS Specifier

The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:

POS = *p*

p	Is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, *p* is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, *p* is assigned the value one.

If there are pending asynchronous data operations for the specified file, the value assigned to the POS= specifier is computed as if all pending data transfers have already completed.

INQUIRE: POSITION Specifier

The POSITION specifier asks the position of the file. It takes the following form:

POSITION = *pos*

pos

Is a scalar default character variable that is assigned one of the following values:

'REWIND'	If the file is connected with its position at its initial point
'APPEND'	If the file is connected with its position at its terminal point (or before its end-of-file record, if any)
'ASIS'	If the file is connected without changing its position
'UNDEFINED'	If the file is not connected, or is connected for direct access data transfer and a REWIND statement has not been performed on the unit

INQUIRE: READ Specifier

The READ specifier asks whether a file can be read. It takes the following form:

READ = *rd*

rd

Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be read
'NO'	If the file cannot be read
'UNKNOWN'	If the processor cannot determine whether the file can be read

INQUIRE: READWRITE Specifier

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

READWRITE = *rdwr*

rdwr

Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be both read and written to
'NO'	If the file cannot be both read and written to
'UNKNOWN'	If the processor cannot determine whether the file can be both read and written to

INQUIRE: RECL Specifier

The RECL specifier asks the maximum record length for a file. It takes the following form:

RECL = *rcl*

rcl

Is a scalar integer variable that is assigned a value as follows:

- If the file or unit is connected, the value assigned is the maximum record length allowed.
- If the file does not exist, or it is not connected, the value assigned is zero.

  Fortran 2018 standardizes the value assigned to be -1 when the file does not exist, or it is not connected. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.
- If the file is connected for stream access, the value is undefined. Fortran 2018 standardizes this value to be -2. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer and the `assume byterecl` compiler option is not in effect; otherwise, the value is expressed in bytes.

INQUIRE: RECORDTYPE Specifier

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:

RECORDTYPE = *rtype*

rtype

Is a scalar default character variable that is assigned one of the following values:

'FIXED'	If the file is connected for fixed-length records
'VARIABLE'	If the file is connected for variable-length records
'SEGMENTED'	If the file is connected for unformatted sequential data transfer using segmented records
'STREAM'	If the file's records are not terminated
'STREAM_CR'	If the file's records are terminated with a carriage return
'STREAM_LF'	If the file's records are terminated with a line feed
'STREAM_CRLF'	If the file's records are terminated with a carriage return/line feed pair
'UNKNOWN'	If the file is not connected

INQUIRE: ROUND Specifier

The ROUND specifier asks which rounding mode is in effect for a file connection. It takes the following form:

ROUND = *rmode*

rmode

Is a scalar default character expression that is assigned one of the following values:

'UP'	If the I/O rounding is set to the smallest representable value that is greater than or equal to the original value.
'DOWN'	If the I/O rounding is set to the largest representable value that is less than or equal to the original value.
'ZERO'	If the I/O rounding is set to the value closest to the original value, but no greater in magnitude than the original value.
'NEAREST'	Conforms to the ISO/IEC 60559:2020 standard specification for roundTiesToEven.
'COMPATIBLE'	If the I/O rounding is set to the closer of the two nearest representable values, or the value farther from zero if halfway between them.
'PROCESSOR_DEFINED'	If the I/O rounding mode behaves differently than the UP, DOWN, ZERO, NEAREST, and COMPATIBLE modes.
'UNDEFINED'	If there is no connection or if the connection is not for formatted I/O.

The rounding modes conform to the corresponding rounding modes specified in the ISO/IEC 60559:2020 standard.

INQUIRE: SEQUENTIAL Specifier

The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

SEQUENTIAL = *seq*

seq Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for sequential access
'NO'	If the file is not connected for sequential access
'UNKNOWN'	If the processor cannot determine whether the file is connected for sequential access

INQUIRE: SHARE Specifier

The SHARE specifier asks the current share status of a file or unit. It takes the following form:

SHARE = *shr*

shr

Is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

'DENYRW'	If the file is connected for deny-read/write mode
'DENYWR'	If the file is connected for deny-write mode
'DENYRD'	If the file is connected for deny-read mode
'DENYNONE'	If the file is connected for deny-none mode
'UNKNOWN'	If the file or unit is not connected

On Linux* systems, this variable is assigned one of the following values:

'DENYRW'	If the file is connected for exclusive access
'DENYNONE'	If the file is connected for shared access
'NODENY'	If the file is connected with default locking
'UNKNOWN'	If the file or unit is not connected

INQUIRE: SIGN Specifier

The SIGN specifier asks what treatment for plus signs is in effect during a connection. It takes the following form:

SIGN = *sn*

sn

Is a scalar default character expression that is assigned one of the following values:

'PLUS'	If the file is connected with addition of plus signs in effect.
'SUPPRESS'	If the file is connected with suppression of plus signs in effect.
'PROCESSOR_DEFINED'	If the file is connected with plus signs added at the discretion of the processor.
'UNDEFINED'	If there is no connection, or if the connection is not for formatted input/output.

INQUIRE: SIZE Specifier

The SIZE specifier asks the size of a file in file storage units. It takes the following form:

SIZE = *sz*

sz — Is a scalar integer variable.

The *sz* variable is assigned the size of the file in file storage units. If the file size cannot be determined, the variable is assigned the value -1.

For a file that is connected for stream access, the file size is the number of the highest-numbered file storage unit in the file.

For a file that is connected for sequential or direct access, the file size may be different from the number of storage units implied by the data in the records; the exact relationship is processor-dependent.

If there are pending asynchronous data transfer operations for the specified file, the value assigned to the SIZE= specifier is computed as if the pending data transfers have already completed.

INQUIRE: UNFORMATTED Specifier

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

UNFORMATTED = *unf*

unf — Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for unformatted data transfer
'NO'	If the file is not connected for unformatted data transfer
'UNKNOWN'	If the processor cannot determine whether the file is connected for unformatted data transfer

INQUIRE: WRITE Specifier

The WRITE specifier asks whether a file can be written to. It takes the following form:

WRITE = *wr*

wr — Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be written to
'NO'	If the file cannot be written to
'UNKNOWN'	If the processor cannot determine whether the file can be written to

OPEN Statement Specifiers

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.

The following table summarizes details about the OPEN statement specifiers and it contains links to their descriptions:

OPEN Statement Specifiers and Values

Specifier	Values	Function	Default
ACCESS	'DIRECT' 'SEQUENTIAL' 'STREAM' 'APPEND'	Access mode	'SEQUENTIAL'
ACTION (or MODE)	'READ' 'WRITE' 'READWRITE'	File access	'READWRITE'
ASSOCIATEVARIABLE	A scalar integer variable	Next direct access record	No default
ASYNCHRONOUS	'YES' 'NO'	Asynchronous I/O	'NO'
BLANK	'NULL' 'ZERO'	Interpretation of blanks	'NULL'
BLOCKSIZE	A scalar numeric expression	Physical I/O transfer size	131,072 bytes
BUFFERCOUNT	A scalar numeric expression	Number of I/O buffers	One
BUFFERED	'YES' 'NO'	Buffering for WRITE operations; buffering for READ operations on variable length, unformatted, input records	'NO' Note: The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.
CARRIAGECONTROL	'FORTRAN' 'LIST' 'NONE'	Print control	Formatted: 'LIST' Note: If you specify compiler option `vms`, and the unit is connected to a terminal, the default is 'FORTRAN'. Unformatted: 'NONE'
CONVERT	'LITTLE_ENDIAN' 'BIG_ENDIAN' 'CRAY' 'FDX' 'FGX' 'IBM' 'VAXD'	Numeric format specification	'NATIVE'

Specifier	Values	Function	Default
	'VAXG' 'NATIVE'		
DECIMAL	'COMMA' 'POINT'	Decimal edit mode	'POINT'
DEFAULTFILE	A scalar default character expression	Default file pathname	Current working directory
DELIM	'APOSTROPHE' 'QUOTE' 'NONE'	Delimiter for character constants	'NONE'
DISPOSE (or DISP)	'KEEP' or 'SAVE' 'DELETE' 'PRINT' 'PRINT/DELETE' 'SUBMIT' 'SUBMIT/DELETE'	File disposition at close	'KEEP'
ENCODING	'UTF-8' 'DEFAULT'	Encoding form for a file	'DEFAULT'
ERR	A statement label	Error transfer control	No default
FILE (or NAME)	A scalar default character expression	File pathname (file name)	fort.*n*, where *n* is the unit number.
FORM	'FORMATTED' 'UNFORMATTED' 'BINARY'	Format type	Depends on ACCESS setting
IOFOCUS	.TRUE. .FALSE.	Active window in QuickWin application	.TRUE. Note: If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..
IOSTAT	A scalar integer variable	I/O status	No default
MAXREC	A scalar numeric expression	Direct access record limit	No limit
NEWUNIT	A scalar integer variable	Returns automatically chosen, unused, unit number	No default
NOSHARED	No value	File sharing disallowed	Linux: SHARED Windows: Not shared
ORGANIZATION	'SEQUENTIAL' 'RELATIVE'	File organization	'SEQUENTIAL'
PAD	'YES'	Record padding	'YES'

Specifier	Values	Function	Default
	'NO'		
POSITION	'ASIS' 'REWIND' 'APPEND'	File positioning	'ASIS'
READONLY	No value	Write protection	No default
RECL (or RECORDSIZE)	A scalar numeric expression	Record length	Depends on RECORDTYPE,ORGANIZATION, and FORM settings Note: On Linux* systems, the default depends only on the FORM setting.
RECORDTYPE	'FIXED' 'VARIABLE' 'SEGMENTED' 'STREAM' 'STREAM_CR' 'STREAM_LF'	Record type	Depends on ORGANIZATION, CARRIAGECONTROL, ACCESS, and FORM settings
ROUND	'UP' 'DOWN' 'ZERO' 'NEAREST' 'COMPATIBLE' 'PROCESSOR_DEFINED'	Rounding mode	'PROCESSOR_DEFINED' - this corresponds to 'NEAREST' as in the ISO/IEC 60559:2020 standard specification for roundTiesToEven
SHARE	'DENYRW' 'DENYWR' 'DENYRD' 'DENYNONE'	File locking	'DENYWR' Note: The default differs under certain conditions (see SHARE Specifier). Other notes: • 'DENYWR': On Linux* systems, the default depends only on the FORM setting. • 'DENYRD': Applies to Windows.
SHARED	No value	File sharing allowed	Linux*: SHARED Windows: Not shared
SIGN	'PLUS' 'SUPPRESS' 'PROCESSOR_DEFINED'	Plus sign mode	'PROCESSOR_DEFINED'

Specifier	Values	Function	Default
STATUS (or TYPE)	'OLD' 'NEW' 'SCRATCH' 'REPLACE' 'UNKNOWN'	File status at open	'UNKNOWN' Note: The default differs under certain conditions (see STATUS Specifier).
TITLE	A scalar default character expression	Title for child window in a QuickWin application	No default
UNIT	A scalar numeric expression	Logical unit number	No default; an io-unit must be specified.
USEROPEN	An external function	User program option	No default

See Also

INQUIRE Statement for details on using the INQUIRE statement to get file attributes of existing files

OPEN: ACCESS Specifier

The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:

ACCESS = *acc*

acc Is a scalar default character expression that evaluates to one of the following values:

'DIRECT'	Indicates direct access.
'SEQUENTIAL'	Indicates sequential access.
'STREAM'	Indicates stream access, where the file storage units of the file are accessible sequentially or by position.
'APPEND'	Indicates sequential access, but the file is positioned at the end-of-file record.

The default is 'SEQUENTIAL'.

There are limitations on record access by file organization and record type.

OPEN: ACTION Specifier

The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:

ACTION = *act*

act Is a scalar default character expression that evaluates to one of the following values:

'READ'	Indicates that only READ statements can refer to this connection.

'WRITE'	Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.
'READWRITE'	Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.

The default is 'READWRITE'.

However, if compiler option fpscomp general is specified on the command line and *action* is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting *action* is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

See Also

fpscomp compiler option

OPEN: ASSOCIATEVARIABLE Specifier

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

ASSOCIATEVARIABLE = *asv*

asv	Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of *asv*.

This specifier is valid only for direct access; it is ignored for other access modes.

OPEN: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

ASYNCHRONOUS = *asyn*

asyn	Is a scalar expression of type default character that evaluates to one of the following values:

'YES'	Indicates that asynchronous I/O is allowed for a unit.
'NO'	Indicates that asynchronous I/O is not allowed for a unit.

The default is 'NO'.

OPEN: BLANK Specifier

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

BLANK = *blnk*

blnk Is a scalar default character expression that evaluates to one of the following values:

'NULL'	Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).
'ZERO'	Indicates all blanks (other than leading blanks) are treated as zeros.

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

This specifier is not allowed on unformatted input or output.

See Also

Blank Editing for details on the BN and BZ edit descriptors

f66

OPEN: BLOCKSIZE Specifier

The BLOCKSIZE specifier indicates the physical I/O transfer size in bytes for the file. It takes the following form:

BLOCKSIZE = *bks*

bks Is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for *bks*, it is rounded up to a multiple of 512 byte blocks. The maximum valid value of BLOCKSIZE is 2147467264.

If you do not specify BLOCKSIZE or you specify zero for *bks*, the default value of 128 KB (131,072 bytes) is assumed. However, if you compile with the `assume buffered_stdout` option, the default blocksize for `stdout` is 8 KB.

The default BLOCKSIZE value can be changed by using the FORT_BLOCKSIZE environment variable or by specifying the BLOCKSIZE parameter on the unit's OPEN. The BLOCKSIZE value can be changed for `stdout` by re-opening the unit corresponding to stdout with an explicit BLOCKSIZE parameter; for example:

```
OPEN(6,ACCESS='SEQUENTIAL',FORM='FORMATTED',BUFFERED='YES',BLOCKSIZE=1048576
```

OPEN: BUFFERCOUNT Specifier

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

BUFFERCOUNT = *bc*

bc Is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for *bc*, the default is 1.

See Also

BLOCKSIZE specifier

OPEN: BUFFERED Specifier

The BUFFERED specifier indicates runtime library behavior for READ and WRITE operations. Buffering of input records only applies to variable length, unformatted records. This specifier takes the following form:

BUFFERED = *bf*

bf Is a scalar default character expression that evaluates to one of the following values:

'NO'	For WRITE operations: Requests that the runtime library send output data to the file system after each operation. For READ operations on variable length, unformatted files: Requests that the runtime library transfer input data directly from disk to user variables for each operation.
'YES'	Requests that the runtime library accumulate data in its internal buffer, possibly across several READ or WRITE operations, before the data is transferred to, or from, the file system. Buffering may improve runtime performance for output-intensive applications.

The default is 'NO' for buffering output. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If both BLOCKSIZE and BUFFERCOUNT for OPEN have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. Otherwise, the default size of the internal buffer is 8 KB (8192 bytes).

> **NOTE**
> On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

Rules for Unformatted Sequential READ Statements

OPEN: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

CARRIAGECONTROL = *cc*

cc

Is a scalar default character expression that evaluates to one of the following values:

'FORTRAN'	Indicates normal Fortran interpretation of the first character.
'LIST'	Indicates one line feed between records.
'NONE'	Indicates no carriage control processing.

The default for binary (Windows) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option `vms` or `fpscomp general`, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the `fortpr` format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.

Printing of Formatted Records for details on valid control characters for printing

vms compiler option

fpscomp compiler option

OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

CONVERT = *fm*

fm

Is a scalar default character expression that evaluates to one of the following values:

'LITTLE_ENDIAN'[1]	Little endian integer data [2] and IEEE* floating-point data. [3]
'BIG_ENDIAN'[1]	Big endian integer data [2] and IEEE floating-point data. [3]
'CRAY'	Big endian integer data [2] and CRAY* floating-point data of size REAL(8) or COMPLEX(8).
'FDX'	Little endian integer data [2] and VAX* processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).
'FGX'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), G_floating for size REAL(8) or

	COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).
'IBM'	Big endian integer data [2] and IBM* System\370 floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).
'VAXD'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).
'VAXG'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), G_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).
'NATIVE'	No data conversion. This is the default.

[1] INTEGER(1) data is the same for little endian and big endian.

[2] Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or INTEGER(8)

[3] Of the appropriate size and type: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), or COMPLEX(16)

You can use CONVERT to specify multiple formats in a single program, usually one format for each specified unit number.

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a runtime message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

Method Used	Precedence
An environment variable	Highest
OPEN (CONVERT=)	.
OPTIONS/CONVERT	.
The convert compiler option	Lowest

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY* numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20:

```
   OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED',
1      UNIT=15)
   ...
   OPEN (FILE='graph3_native.dat', FORM='UNFORMATTED', UNIT=20)
```

Data Types, Constants, and Variables for details on supported ranges for data types

convert compiler option

OPEN: DECIMAL Specifier

The DECIMAL specifier controls the representation of the decimal symbol for a connection. It takes the following form:

DECIMAL = *dmode*

dmode Is a scalar default character expression that evaluates to one of the following values:

'COMMA'	Indicates that a decimal comma should be used for decimal editing mode.
'POINT'	Indicates that a decimal point should be used for decimal editing mode.

The default decimal editing mode is 'POINT'.

You can only use this specifier for a formatted I/O connection.

When the mode is DECIMAL='POINT', the decimal point in a numeric input or output value is a period, values are separated by commas in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a comma.

When the mode is DECIMAL='COMMA', the decimal point in a numeric input or output value is a comma, values are separated by semicolons in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a semicolon.

The decimal editing mode can be temporarily changed within a READ or WRITE statement by the DECIMAL= specifier or by the corresponding DC and DP edit descriptors.

This specifier is not allowed on unformatted input or output.

OPEN: DEFAULTFILE Specifier

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

DEFAULTFILE = *def*

def Is a character expression indicating a default file pathname string.

The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE.

If *def* does not end in a slash (/), a slash is added.

If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

OPEN: DELIM Specifier

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

DELIM = *del*

del Is a scalar default character expression that evaluates to one of the following values:

'APOSTROPHE'	Indicates apostrophes delimit character constants. All internal apostrophes are doubled.
'QUOTE'	Indicates quotation marks delimit character constants. All internal quotation marks are doubled.
'NONE'	Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.

The default is 'NONE'.

The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input.

This specifier is not allowed on unformatted input or output.

OPEN: DISPOSE Specifier

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:

DISPOSE = *dis*

DISP = *dis*

dis Is a scalar default character expression that evaluates to one of the following values:

'KEEP' or 'SAVE'	Retains the file after the unit closes.
'DELETE'	Deletes the file after the unit closes.
'PRINT' [1]	Submits the file to the line printer spooler and retains it.
'PRINT/DELETE' [1]	Submits the file to the line printer spooler and then deletes it.
'SUBMIT'	Forks a process to execute the file.
'SUBMIT/DELETE'	Forks a process to execute the file, and then deletes the file after the fork is completed.

[1] Use only on sequential files.

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

On Windows*, PRINT and the PRINT part of PRINT/DELETE do not use the system PRINT command. One of the following occurs:

- If you set the environment variable FOR_DEFAULT_PRINT_DEVICE to a print device, the Fortran runtime will copy the file to that device.
- Otherwise, the Fortran runtime will copy the file to a new file named "PRN-FILE". In this case, you will need to do the actual printing

OPEN: ENCODING Specifier

The ENCODING specifier indicates the encoding form for a file. It takes the following form:

ENCODING = *enc*

enc

Is a scalar default character expression that evaluates to one of the following values:

'UTF-8'	Indicates that the encoding form of the file is UTF-8 (a unicode file). All characters therein are of ISO 10646 character type, as specified by ISO/IEC 10646-1:2000. This value must not be specified if the processor does not support the ISO 10646 character type.
'DEFAULT'	Indicates that the encoding form of the file is determined by the processor.

The default is 'DEFAULT'.

You can only use this specifier for a formatted I/O connection.

OPEN: FILE Specifier

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:

FILE = *name*

name

Is a character or numeric expression.

The *name* can be any pathname allowed by the operating system.

Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
- The unit is not connected to a file
- STATUS='SCRATCH' is not specified
- The corresponding FORT*n* environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort.*n*, where *n* is the logical unit number. On Windows systems, if compiler option fpscomp general is specified, omitting FILE implies STATUS='SCRATCH'.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console. .

In a Windows* QuickWin application, you can specify FILE='USER' to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the *name* can be blank (FILE=' ') if the compatibility compiler option fpscomp filesfromcmd is specified. If the *name* is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (" "), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.
2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

   Assume the following command line started the program MYPROG (note that quotation marks (") are used):

   myprog first.fil " " third.txt

   MYPROG contains four OPEN statements with blank filenames, in the following order:

```
OPEN (2, FILE = ' ')
OPEN (4, FILE = ' ')
OPEN (5, FILE = ' ')
OPEN (10, FILE = ' ')
```

   Unit 2 is associated with the file FIRST.FIL. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

```
Filename missing or blank - Please enter name UNIT 4?
```

   Unit 5 is associated with the file THIRD.TXT. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

```
Filename missing or blank - Please enter name UNIT 10?
```

fpscomp compiler option

OPEN: FORM Specifier

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or binary (Windows) data transfer. It takes the following form:

FORM = *fm*

fm Is a scalar default character expression that evaluates to one of the following values:

'FORMATTED'	Indicates formatted data transfer
'UNFORMATTED'	Indicates unformatted data transfer
'BINARY'	Indicates binary data transfer

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.

The data is stored and retrieved in a file according to the file's access (set by the ACCESS specifier) and the form of the data the file contains.

A *formatted file* is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.

An *unformatted file* is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

Binary sequential files are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.

Binary direct files have very little structure. A record length is assigned by the RECL specifier in an OPEN statement. This establishes record boundaries, which are used only for repositioning and padding before and after read and write operations and during BACKSPACE operations. Record boundaries do not restrict the number of bytes that can be transferred during a read or write operation. If an I/O operation attempts to read or write more values than are contained in a record, the read or write operation is continued on the next record.

Fortran standard stream access provides similar functionality to FORM='BINARY'. This is specified using ACCESS='STREAM'.

See Also

Record Access

OPEN: IOFOCUS Specifier

The IOFOCUS specifier indicates whether a particular unit is the active window in a QuickWin application. This specifier is only available for Windows. It takes the following form:

IOFOCUS = *iof*

iof Is a scalar default logical expression that evaluates to one of the following values:

.TRUE.	Indicates the QuickWin child window is the active window
.FALSE.	Indicates the QuickWin child window is not the active window

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window. OUTTEXT, OUTGTEXT, or any other graphics routine call does not cause the focus to shift.

OPEN: MAXREC Specifier

The MAXREC specifier indicates the maximum number of records that can be transferred from or to a direct access file while the file is connected. It takes the following form:

MAXREC = *mr*

mr Is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

The default is an unlimited number of records.

OPEN: MODE Specifier

MODE is a nonstandard synonym for ACTION.

OPEN: NAME Specifier

NAME is a nonstandard synonym for FILE.

OPEN: NEWUNIT Specifier

The NEWUNIT specifier opens a file on an unused unit number that is automatically chosen. It also returns the unit number that was chosen. It takes the following form:

NEWUNIT = *u-var*

u-var	Is a scalar integer variable that is assigned the automatically chosen unit number. It is always a negative integer.

If the OPEN is successful, *u-var* can be used in subsequent I/O statements to access the connected file.

If an error occurs during execution of the OPEN statement containing the NEWUNIT= speciifier, the processor does not change the value of the variable.

OPEN: NOSHARED Specifier

The NOSHARED specifier indicates that the file is connected for exclusive access by the program. It takes the following form:

NOSHARED

OPEN: ORGANIZATION Specifier

The ORGANIZATION specifier indicates the internal organization of the file. It takes the following form:

ORGANIZATION = *org*

org — Is a scalar default character expression that evaluates to one of the following values

'SEQUENTIAL'	Indicates a sequential file.
'RELATIVE'	Indicates a relative file.

The default is 'SEQUENTIAL'.

OPEN: PAD Specifier

The PAD specifier indicates whether a formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

The PAD specifier takes the following form:

PAD = *pd*

pd — Is a scalar default character expression that evaluates to one of the following values:

'YES'	Indicates the record will be padded with blanks when necessary.
'NO'	Indicates the record will not be padded with blanks. The input record must contain the data required by the input list and format specification.

The default is 'YES'.

This behavior is different from FORTRAN 77, which never pads short records with blanks and doesn't support the PAD= qualifier. For example, consider the following:

```
READ (5,'(I5)') J
```

If you enter 123 followed by a carriage return, FORTRAN 77 will issue the ENDRECDUR error message.

However, Intel® Fortran pads the 123 with 2 blanks unless you explicitly open the unit with PAD='NO'.

You can override blank padding by explicitly specifying the BN edit descriptor.

The PAD specifier is ignored during output.

This specifier is not allowed on unformatted input or output.

OPEN: POSITION Specifier

The POSITION specifier indicates the position of a file connected for sequential access. It takes the following form:

POSITION = *pos*

pos Is a scalar default character expression that evaluates to one of the following values:

'ASIS'	Indicates the file position is unchanged if the file exists and is already connected. The position is unspecified if the file exists but is not connected.
'REWIND'	Indicates the file is positioned at its initial point.
'APPEND'	Indicates the file is positioned at its terminal point (or before its end-of-file record, if any).

The default is 'ASIS'.

A new file (whether specified as new explicitly or by default) is always positioned at its initial point.

In addition to the POSITION specifier, you can use position statements. The BACKSPACE statement positions a file back one record. The REWIND statement positions a file at its initial point. The ENDFILE statement writes an end-of-file record at the current position and positions the file after it. Note that ENDFILE does not go the end of an existing file, but creates an end-of-file where it is.

OPEN: READONLY Specifier

The READONLY specifier indicates only READ statements can refer to this connection. It takes the following form:

READONLY

READONLY is similar to specifying ACTION='READ', but READONLY prevents deletion of the file if it is closed with STATUS='DELETE' in effect.

The Fortran I/O system's default privileges for file access are READWRITE. If access is denied, the I/O system automatically retries accessing the file for READ access.

However, if you use compiler option vms, the I/O system does not retry accessing for READ access. So, runtime I/O errors can occur if the file protection does not permit WRITE access. To prevent such errors, if you wish to read a file for which you do not have write access, specify READONLY.

OPEN: RECL Specifier

The RECL specifier indicates the length of each record in a file connected for direct access, or the maximum length of a record in a file connected for sequential access.

The RECL specifier takes the following form:

RECL = *rl*

rl Is a positive numeric expression indicating the length of records in the file. If necessary, the value is converted to integer data type before use.

If the file is connected for formatted data transfer, the value must be expressed in bytes (characters). Otherwise, the value is expressed in 4-byte units (longwords). If the file is connected for unformatted data transfer, the value can be expressed in bytes if compiler option assume byterecl is specified.

Except for segmented records, the *rl* is the length for record data only, it does not include space for control information. If *rl* is too large, you can exhaust your program's virtual memory resources trying to create room for the record.

The length specified is interpreted depending on the type of records in the connected file, as follows:

- For segmented records, RECL indicates the maximum length for any segment (including the four bytes of control information).
- For fixed-length records, RECL indicates the size of each record; it *must* be specified. If the records are unformatted, the size must be expressed as an even multiple of four.

  You can use the RECL specifier in an INQUIRE statement to get the record length before opening the file.
- For variable-length records, RECL indicates the maximum length for any record.

If you read a fixed-length file with a record length different from the one used to create the file, indeterminate results can occur.

The maximum length for *rl* depends on the record type and the setting of the CARRIAGECONTROL specifier, as shown in the following table:

Maximum Record Lengths (RECL)

Record Type	CARRIAGECONTROL	Formatted (size in bytes)
Fixed-length	'NONE'	Unlimited
Variable-length	'NONE'	2147483640 (2**31-8)
Segmented	'NONE'	32764 (2**15-4)
Stream	'NONE'	2147483647 (2**31-1)
Stream_CR	'LIST'	2147483647 (2**31-1)
	'FORTRAN'	2147483646 (2**31-2)
Stream_LF	'LIST'	2147483647 (2**31-1) [1]
	'FORTRAN'	2147483646 (2**31-2)

[1] Linux only

The default value depends on the setting of the RECORDTYPE specifier, as shown in the following table:

Default Record Lengths (RECL)

RECORDTYPE	RECL value
'FIXED'	None; value must be explicitly specified.
All other settings	132 bytes for formatted records; 510 longwords for unformatted records.[1]

[1]To change the default record length values, you can use environment variable FORT_FMT_RECL or FORT_UFMT_RECL.

For formatted records with other than RECORDTYPE='FIXED', the default RECL is 132.

There is a property of list-directed sequential WRITE statements called the *right margin*. If you do not specify RECL as an OPEN statement specifier or in environmental variable FORT_FMT_RECL, the right margin value defaults to 80. When RECL is specified, the right margin is set to the value of RECL. If the length of a list-directed sequential WRITE exceeds the value of the *right margin* value, the remaining characters will wrap to the next line. Therefore, writing 100 characters will produce two lines of output, and writing 180 characters will produce three lines of output. You can turn off the *right margin* using the `wrap-margin` compiler option or the FORT_FMT_NO_WRAP_MARGIN environment variable.

vms compiler option
Record Transfer

OPEN: RECORDSIZE Specifier

RECORDSIZE is a nonstandard synonym for RECL.

OPEN: RECORDTYPE Specifier

The RECORDTYPE specifier indicates the type of records in a file. It takes the following form:

RECORDTYPE = *typ*

typ Is a scalar default character expression that evaluates to one of the following values:

'FIXED'	Indicates fixed-length records.
'VARIABLE'	Indicates variable-length records.
'SEGMENTED'	Indicates segmented records.
'STREAM'	Indicates stream-type variable length data with no record terminators.
'STREAM_LF'	Indicates stream-type variable length records, terminated with a line feed.
'STREAM_CR'	Indicates stream-type variable length records, terminated with a carriage return.
'STREAM_CRLF'	Indicates stream-type variable length records, terminated with a carriage return/line feed pair.

When you open a file, default record types are as follows:

'FIXED'	For relative files
'FIXED'	For direct access sequential files
'STREAM_LF'	For formatted sequential access files on Linux* systems
'STREAM_CRLF'	For formatted sequential access files on Windows systems
'VARIABLE'	For unformatted sequential access files

A *segmented record* is a logical record consisting of segments that are physical records. Since the length of a segmented record can be greater than 65,535 bytes, only use segmented records for unformatted sequential access to disk or raw magnetic tape files.

Files containing segmented records can be accessed only by unformatted sequential data transfer statements.

If an output statement does not specify a full record for a file containing fixed-length records, the following occurs:

- In formatted files, the record is filled with blanks
- In unformatted files, the record is filled with zeros

OPEN: ROUND Specifier

The ROUND specifier indicates the I/O rounding mode for the duration of a connection. It takes the following form:

ROUND = *rmode*

rmode Is a scalar default character expression that evaluates to one of the following values:

'UP'	The smallest representable value that is greater than or equal to the original value.
'DOWN'	The largest representable value that is less than or equal to the original value.
'ZERO'	The value closest to the original value, but no greater in magnitude than the original value.
'NEAREST'	Conforms to the ISO/IEC 60559:2020 standard specification for `roundTiesToEven`.
'COMPATIBLE'	The closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero.
'PROCESSOR_DEFINED'	The value is determined by the default settings in the processor, which may correspond to one of the other modes.

The default I/O rounding mode is 'PROCESSOR_DEFINED'. This corresponds to 'NEAREST'.

The rounding modes conform to the corresponding rounding modes specified in the ISO/IEC 60559:2020 standard.

You can only use this specifier for a formatted I/O connection.

The rounding mode can be temporarily changed within a READ or WRITE statement by the corresponding RU, RD, RZ, RN, RC, and RP edit descriptors.

This specifier is not allowed on unformatted input or output.

OPEN: SHARE Specifier

The SHARE specifier indicates whether file locking is implemented while the unit is open. It takes the following form:

SHARE = *shr*

shr Is a scalar default character expression.

On Windows* systems, this expression evaluates to one of the following values:

'DENYRW'	Indicates deny-read/write mode. No other process can open the file.
'DENYWR'	Indicates deny-write mode. No process can open the file with write access.
'DENYRD'	Indicates deny-read mode. No process can open the file with read access.
'DENYNONE'	Indicates deny-none mode. Any process can open the file in any mode.
On Linux* systems, this expression evaluates to one of the following values:	
'DENYRW'	Indicates exclusive access for cooperating processes.
'DENYNONE'	Indicates shared access for cooperating processes.

On Windows systems, the default is 'DENYWR'. However, if you specify compiler option fpscomp general or the SHARED specifier, the default is 'DENYNONE'.

On Linux systems, no restrictions are applied to file opening if you do not use a locking mechanism.

'COMPAT' is accepted for compatibility with previous versions. It is equivalent to 'DENYNONE'.

Use the ACCESS specifier in an INQUIRE statement to determine the access permission for a file.

Be careful not to permit other users to perform operations that might cause problems. For example, if you open a file intending only to read from it, and want no other user to write to it while you have it open, you could open it with ACTION='READ' and SHARE='DENYRW'. Other users would not be able to open it with ACTION='WRITE' and change the file.

Suppose you want several users to read a file, and you want to make sure no user updates the file while anyone is reading it. First, determine what type of access to the file you want to allow the original user. Because you want the initial user to read the file only, that user should open the file with ACTION='READ'. Next, determine what type of access the initial user should allow other users; in this case, other users should be able only to read the file. The first user should open the file with SHARE='DENYWR'. Other users can also open the same file with ACTION='READ' and SHARE='DENYWR'.

See Also

fpscomp compiler option

OPEN: SHARED Specifier

The SHARED specifier indicates that the file is connected for shared access by more than one program executing simultaneously. It takes the following form:

SHARED

On Linux* systems, shared access is the default for the Fortran I/O system. On Windows* systems, it is the default if SHARED or compiler option fpscomp general is specified.

See Also

fpscomp compiler option

OPEN: SIGN Specifier

The SIGN specifier controls the optional plus characters in formatted numeric output created during the connection. It takes the following form:

SIGN = *sn*

sn Is a scalar default character expression that evaluates to one of the following values:

'PLUS'	Indicates that the processor should produce a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SP edit descriptor.
'SUPPRESS'	Indicates that the processor should suppress a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SS edit descriptor.
'PROCESSOR_DEFINED'	Indicates that the processor determines whether a plus sign is added in any subsequent position where it would be otherwise optional. This has the same effect as the S edit descriptor.

The default is 'PROCESSOR_DEFINED'.

The setting can be overwritten by a SIGN= specifier in a WRITE statement.

This specifier is not allowed on unformatted input or output.

OPEN: STATUS Specifier

The STATUS specifier indicates the status of a file when it is opened. It takes the following form:

STATUS = *sta*

sta Is a scalar default character expression that evaluates to one of the following values:

'OLD'	Indicates an existing file.
'NEW'	Indicates a new file; if the file already exists, an error occurs. Once the file is created, its status changes to 'OLD'.
'SCRATCH'	Indicates a new file that is unnamed (called a scratch file). When the file is closed or the program terminates, the scratch file is deleted.

'REPLACE'	Indicates the file replaces another. If the file to be replaced exists, it is deleted and a new file is created with the same name. If the file to be replaced does not exist, a new file is created and its status changes to 'OLD'.
'UNKNOWN'	Indicates the file may or may not exist. If the file does not exist, a new file is created and its status changes to 'OLD'.

Scratch files go into a temporary directory and are visible while they are open. Scratch files are deleted when the unit is closed or when the program terminates normally, whichever occurs first.

To specify the path for scratch files, you can use one of the following environment variables:

- On Windows*: FORT_TMPDIR, TMP, or TEMP, searched in that order
- On Linux*: FORT_TMPDIR or TMPDIR, searched in that order

If no environment variable is defined, the default is the current directory.

The default is 'UNKNOWN'. This is also the default if you implicitly open a file by using WRITE. However, if you implicitly open a file using READ, the default is 'OLD'. If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'NEW'.

NOTE
The STATUS specifier can also appear in CLOSE statements to indicate the file's status after it is closed. However, in CLOSE statements the STATUS values are the same as those listed for the DISPOSE specifier.

See Also

f66 compiler option

OPEN: TITLE Specifier

The TITLE specifier indicates the name of a child window in a QuickWin application. This specifier is only available for Windows. It takes the following form:

TITLE = *name*

name	Is a character expression.

If TITLE is specified in a non-Quickwin application, a runtime error occurs.

OPEN: TYPE Specifier

TYPE is a nonstandard synonym for STATUS.

OPEN: USEROPEN Specifier

The USEROPEN specifier lets you pass control to a routine that directly opens a file. The file can use system calls or library routines to establish a special context that changes the effect of subsequent Fortran I/O statements.

The USEROPEN specifier takes the following form:

USEROPEN = *function-name*

function-name	Is the name of an external function. The external function can be written in Fortran, C, or other languages. The return value is the *file descriptor*. On Linux, the *file descriptor* is a 4-byte integer on both 32-bit and 64-bit systems. On Windows, the *file descriptor* is a 4-byte integer on 32-bit systems and an 8-byte integer on 64-bit systems.

If the function is written in Fortran, do not execute a Fortran OPEN statement to open the file named in USEROPEN.

The Intel© Fortran Runtime Library (RTL) I/O support routines call the function named in USEROPEN in place of the system calls normally used when the file is first opened for I/O.

On Windows* systems, the Fortran RTL normally calls CreateFile( ) to open a file. When USEROPEN is specified, the called function opens the file (or pipe, etc.) by using CreateFile( ) and returns the *handle* of the file (return value from CreateFile( )) when it returns control to the calling Fortran program.

On Linux* systems, the Fortran RTL normally calls the open function to open a file. When USEROPEN is specified, the called function opens the file by calling open and returns the file descriptor of the file when it returns control to the calling Fortran program.

When opening the file, the called function usually specifies options different from those provided by a normal Fortran OPEN statement.

NOTE
You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the runtime library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function.

For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures/ USEROPEN Specifier.

Compilation Control Lines and Statements

In addition to specifying options on the compiler command line, you can specify the following lines and statements in a program unit to influence compilation:

- The INCLUDE Line

  Incorporates external source code into programs.
- The OPTIONS Statement

  Sets options usually specified in the compiler command line. OPTIONS statement settings override command line options.

Directive Enhanced Compilation

Directive enhanced compilation is performed by using compiler directives. Compiler directives are special commands that let you perform various tasks during compilation. They are similar to compiler options, but can provide more control within your program.

Compiler directives are preceded by a special prefix that identifies them to the compiler.

Syntax Rules for Compiler Directives

The following syntax rules apply to all general and OpenMP* Fortran compiler directives. You must follow these rules precisely to compile your program properly and obtain meaningful results.

A directive prefix (tag) takes one of the following forms:

General compiler directives:	!DIR$
OpenMP Fortran compiler directives:	!$OMP
Compiler directives that are extension to OpenMP:	!$OMPX (free format), !$OMX (fixed format)

In fixed-format source, the following prefix forms can be used in place of !DIR$: *c*DIR$, *c*DEC$, or !MS$, where *c* is one of the following: C (or c), !, or *.

In fixed-format source, the following prefix forms can be used in place of !$OMP: *c*$OMP, and in place of !$OMX: c$OMX, where *c* is one of the following: C (or c), !, or *.

The following are source form rules for directive prefixes:

- In fixed and tab source forms, prefixes begin with !, C (or c), or *.

  The prefix must appear in columns 1 through 5; column 6 must be a blank or a tab (except for prefix !MS$). From column 7 on, blanks are insignificant, so the directive can be positioned anywhere on the line after column 6.
- In free source form, prefixes begin with !.

  The prefix can appear in any column, but it cannot be preceded by any nonblank, nontab characters on the same line.
- In all source forms, directives spelled with two keywords can be separated by an optional space; for example, "LOOP COUNT" and "LOOPCOUNT" are both valid spellings for the same directive. However, when a directive name is preceded by the prefix "NO", this is not considered to be two keywords. For example, "NO DECLARE" is not a valid spelling; the only valid spelling for this directive is "NODECLARE".

A fixed-format compiler directive ends in column 72 (or column 132, if compiler option extend-source is specified). Free-format directives end in column 132.

General compiler directives and OpenMP Fortran directives can be continued in the same way as Fortran statements can be continued:

- In fixed form, the first line of the directive {initial line} has the directive prefix is in columns 1 through 5 and has a blank, a tab, or a zero in column 6; each continued line of the directive has the directive prefix in columns 1 through 5 and has a character other than a blank, a tab, or a zero in column 6.
- In free form, the initial line of the directive ends with an ampersand followed by an optional comment beginning with an exclamation point. Each continued line of the directive has the directive prefix optionally preceded by blanks or tabs, followed by an ampersand optionally preceded by blanks or tabs.

A comment beginning with an ! can follow a compiler directive on the same line.

Additional Fortran statements (or directives) cannot appear on the same line as the compiler directive.

Compiler directives cannot appear within a continued Fortran statement.

Blank common used in a compiler directive is specified by two slashes (/ /).

If the source line starts with a valid directive prefix but the directive is not recognized, the compiler displays an informational message and ignores the line.

General Compiler Directives

Compiler directives are specially formatted comments in the source file which provide information to the compiler. Some directives, such as line length or conditional compilation directives provide the compiler information which is used in interpreting the source file.

Other directives, such as optimization directives provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler based on the heuristics of the optimizer and/or code generator.

You do not need to specify a compiler option to enable general directives. If the directive is ignored by the compiler, no diagnostic message is issued.

The following is an alphabetical list of general compiler directives:

ALIAS	Specifies an alternate external name to be used when referring to external subprograms.
ASSUME	Provides heuristic information to the compiler optimizer.
ASSUME_ALIGNED	Specifies that an entity in memory is aligned.
ATTRIBUTES	Specifies properties for data objects and procedures.
BLOCK_LOOP and NOBLOCK_LOOP	Enables or disables loop blocking for the immediately following nested DO loops.
DECLARE and NODECLARE	Generates or disables warnings for variables that have been used but not declared.
DEFINE and UNDEFINE	Defines (or undefines) a symbolic variable whose existence (or value) can be tested during conditional compilation.
DISTRIBUTE POINT	Suggests a location at which a DO loop may be split.
FIXEDFORMLINESIZE	Sets the line length for fixed-form source code.
FMA and NOFMA	Enables (or disables) the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.
FREEFORM and NOFREEFORM	Specifies free-format or fixed-format source code.
IDENT	Specifies an identifier for an object module.
IF and IF DEFINED	Specifies a conditional compilation construct.
INLINE, FORCEINLINE, NOINLINE	Tell the compiler to perform the specified inlining on routines within statements or DO loops.
INTEGER	Specifies the default integer kind.
IVDEP	Assists the compiler's dependence analysis of iterative DO loops.
LOOP COUNT	Specifies the typical trip count for a DO loop; this assists the optimizer.
MESSAGE	Specifies a character string to be sent to the standard output device during the first compiler pass.
NOFUSION	Prevents a loop from fusing with adjacent loops.
OBJCOMMENT	Specifies a library search path in an object file.
OPTIMIZE and NOOPTIMIZE	Enables or disables optimizations for the program unit.
OPTIONS	Affects data alignment and warnings about data alignment.
PACK	Specifies the memory alignment of derived-type items.
PARALLEL and NOPARALLEL	Facilitates or prevents auto-parallelization by assisting the compiler's dependence analysis of the immediately following DO loop. This feature is only available for ifort.
PREFETCH and NOPREFETCH	Enables or disables hint to the compiler to prefetch data from memory.
PSECT	Modifies certain characteristics of a common block.
REAL	Specifies the default real kind.
SIMD	Requires and controls SIMD vectorization of loops. This feature is only available for ifort.

STRICT and NOSTRICT	Disables or enables language features not found in the language standard specified on the command line.
UNROLL and NOUNROLL	Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop.
UNROLL_AND_JAM and NOUNROLL_AND_JAM	Enables or disables loop unrolling and jamming.
VECTOR and NOVECTOR	Overrides default heuristics for vectorization of DO loops.

Syntax Rules for Compiler Directives

Rules for Placement of Directives

Directives can have different effects depending on placement:

- Some directives affect the next statement only.
- Some directives can appear only at the beginning of a scope and affect the rest of that scope.
- Some directives affect the statements starting at that point in the source and continue until changed by another directive or until the end of the scope containing the directive.

The scope can be a contained procedure or a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. A directive does not affect modules invoked with the USE statement in the program unit that contains it, but it does affect INCLUDE statements that follow the directive.

Certain directives may appear before program units or between program units in a source file. These directives affect only the next program unit that lexically follows the directive. The effect of the directive ceases at the end of the affected program unit. For example:

```
!dir$ integer:2
program m
integer k
print *, kind(k), kind(42)    ! this prints 2, 2 which means the directive took effect
call sub()
end

subroutine sub()
integer kk
print *, kind(kk), kind(-42)  ! this prints 4, 4 because the INTEGER:2 directive has no effect
here
end
```

The following directives have this behavior:

- ALIAS
- ATTRIBUTES
- DECLARE and NODECLARE
- DEFINE and UNDEFINE
- FIXEDFORMLINESIZE
- FREEFORM and NOFREEFORM
- IDENT
- INTEGER
- OPTIMIZE and NOOPTIMIZE

- PACK
- PREFETCH
- PSECT
- REAL
- STRICT and NOSTRICT

Other rules may apply to these directives. For more information, see the description of each directive.

Rules for General Directives that Affect DO Loops

This table lists the general directives that affect DO loops:

BLOCK_LOOP and NOBLOCK_LOOP	PARALLEL and NOPARALLEL
CODE_ALIGN	PREFETCH and NOPREFETCH
DISTRIBUTE POINT	SIMD
FORCEINLINE	UNROLL and NOUNROLL
INLINE and NOINLINE	UNROLL_AND_JAM
IVDEP	VECTOR and NOVECTOR
LOOP COUNT	
NOFUSION	
NOUNROLL_AND_JAM	

The following rules apply to all of the general directives:

- The directive must precede the DO statement for each DO loop it affects. The DO statement can be any of the following:
  - A counted DO loop
  - A DO WHILE loop
  - A DO CONCURRENT loop
- No source code lines, other than the following, can be placed between the directive statement and the DO statement:
  - One of the other general directives that affect DO loops
  - An OpenMP* Fortran PARALLEL DO directive
  - Comment lines
  - Blank lines

Other rules may apply to these directives. For more information, see the description of each directive.

See Also

Rules for Loop Directives that Affect Array Assignment Statements

Rules for Loop Directives that Affect Array Assignment Statements

When certain loop directives precede an array assignment statement, they affect the implicit loops that are generated by the compiler.

The following loop directives can affect array assignment statements:

BLOCK_LOOP and NOBLOCK_LOOP	NOVECTOR
CODE_ALIGN	PARALLEL and NOPARALLEL
DISTRIBUTE POINT	PREFETCH and NOPREFETCH

FORCEINLINE	SIMD
INLINE and NOINLINE	UNROLL and NOUNROLL
IVDEP	UNROLL_AND_JAM
LOOP COUNT	VECTOR
NOFUSION	
NOUNROLL_AND_JAM	

Usually only one of the general directives can precede the array assignment statement (`one-dimensional-array = expression`) to affect it. The BLOCK_LOOP and NOBLOCK_LOOP directives may precede array assignment statements with any rank variable on the left-hand-side of the assignment.

Other rules may apply to the general directives. For more information, see the description of each directive.

Examples

Consider the following:

```
            REAL A(10), B(10)
            ...
       !DIR$ IVDEP
            A = B + 3
```

This has the same effect as writing the following explicit loop:

```
      !DIR$ IVDEP
            DO I = 1, 10
               A (I) = B (I) + 3
            END DO
```

Rules for General Directives that Affect DO Loops

OpenMP* Fortran Compiler Directives

Intel® Fortran supports OpenMP* Fortran compiler directives that comply with OpenMP Fortran Application Program Interface (API) specification 5.0, most of the OpenMP Version 5.1 and OpenMP Version 5.2 specifications, and some of the OpenMP 6.0 Version TR12 specification.

To use these directives, you must specify compiler option `-qopenmp` (Linux*) or `/Qopenmp` (Windows*). Offloading directives are enabled with option -fopenmp-targets (Linux) or /Qopenmp-targets (Windows).

OpenMP directives are specially formatted Fortran comment lines embedded in the source file which provide the compiler with hints and suggestions for parallelization, optimization, vectorization, and offloading code to accelerator hardware. The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

Options that use OpenMP are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

Unless denoted as a pure directive, OpenMP directives are not allowed in Fortran procedures declared to be PURE.

The following is an alphabetical list of supported OpenMP Fortran directives:

ALLOCATE	Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.
ALLOCATORS	Specifies memory allocators to use for object allocation in Fortran ALLOCATE statements and for their deallocation. This feature is only available for ifx.
ASSUMES	Provides hints to the optimizer about the current compilation unit and all the code it can reach through procedure calls. It is a pure directive. This feature is only available for ifx.
ATOMIC	Specifies that a specific memory location is to be updated atomically.
BARRIER	Synchronizes all the threads in a team.
CANCEL	Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.
CANCELLATION POINT	Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.
CRITICAL	Restricts access for a block of code to only one thread at a time.
DECLARE MAPPER	Declares a user-defined data mapper for derived types and local variables that can subsequently be used in MAP clauses. It is a pure directive. This feature is only available for ifx.
DECLARE REDUCTION	Declares a user-defined reduction for one or more types. It is a pure directive.
DECLARE SIMD	Generates a SIMD procedure. It is a pure directive.
DECLARE TARGET	Causes the creation of a device-specific version of a named routine that can be called from a target region. It is a pure directive. This feature is only available for ifx.
DECLARE VARIANT	Identifies a variant of a base procedure and specifies the context in which this variant is used. It is a pure directive. This feature is only available for ifx.
DEPOBJ	Initializes, updates, or uninitializes an OpenMP depend object. This feature is only available for ifx.
DISPATCH	Determines if a variant of a base procedure is to be called for a given subroutine or function call. This feature is only available for ifx.
DISTRIBUTE	Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.
DISTRIBUTE PARALLEL DO	Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
DISTRIBUTE PARALLEL DO SIMD	Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
DISTRIBUTE SIMD	Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.
DO	Specifies that the iterations of the immediately following DO loop must be executed in parallel.

DO SIMD	Specifies a loop that can be executed concurrently using SIMD instructions.
ERROR	Causes the compiler or runtime system to process an error condition. It is a pure directive if COMPILATION is specified for the AT clause, or the AT clause does not appear. This feature is only available for ifx.
FLUSH	Specifies synchronization points where the threads in a team must have a consistent view of memory.
GROUPPRIVATE	Specifies that a variable is replicated once per group of threads participating in a parallel region. This feature is only available for ifx.
INTEROP	Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.
LOOP	Specifies that the iterations of the associated loops can execute concurrently. This feature is only available for ifx.
MASKED	Specifies a block of code to be executed by a subset of threads of the current team. This feature is only available for ifx.
MASKED TASKLOOP	Provides an abbreviated way to specify a TASKLOOP construct inside a MASKED construct. This feature is only available for ifx.
MASKED TASKLOOP SIMD	Provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASKED construct. This feature is only available for ifx.
MASTER construct	Deprecated; see MASKED. Specifies a block of code to be executed by the master thread of the team.
MASTER TASKLOOP	Deprecated; provides an abbreviated way to specify a TASKLOOP construct inside a MASTER construct. This feature is only available for ifx.
MASTER TASKLOOP SIMD	Deprecated; provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASTER construct. This feature is only available for ifx.
METADIRECTIVE	Specifies variant OpenMP directives, one of which may conditionally replace the metadirective based on the OpenMP context enclosing the metadirective. This feature is only available for ifx.
NOTHING	Provides documentary clarity in conditionally compiled code or conditional OpenMP* code. It has no effect on the semantics or execution of the program. It is a pure directive. This feature is only available for ifx.
ORDERED	Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.
PARALLEL	Defines a parallel region.
PARALLEL DO	Defines a parallel region that contains a single DO directive.
PARALLEL DO SIMD	Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.
PARALLEL LOOP	Specifies a shortcut for indicating that a loop or loop nest can execute concurrently across multiple threads. This feature is only available for ifx.
PARALLEL MASKED	Provides an abbreviated way to specify a MASKED construct inside a PARALLEL construct. This feature is only available for ifx.

PARALLEL MASKED TASKLOOP	Provides an abbreviated way to specify a MASKED TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASKED TASKLOOP SIMD	Provides an abbreviated way to specify a MASKED TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER	Deprecated; provides an abbreviated way to specify a MASTER construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP SIMD	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL SECTIONS	Defines a parallel region that contains a single SECTIONS directive.
PARALLEL WORKSHARE	Defines a parallel region that contains a single WORKSHARE directive.
PREFETCH DATA	Suggests to the compiler to preload data into cache. Preloading data in cache minimizes the effects of memory latency. It is a pure directive. This feature is only available for ifx.
REQUIRES	Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.
SCAN	Specifies a scan computation that updates each list item in each iteration of the loop the directive appears in.
SCOPE	Specifies a block of code to be executed by all threads in a team. This feature is only available for ifx.
SECTIONS	Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team.
SIMD	Requires and controls SIMD vectorization of loops. It is a pure directive.
SINGLE	Specifies a block of code to be executed by only one thread in a team at a time.
TARGET	Creates a device data environment and executes the construct on the same device. This feature is only available for ifx.
TARGET DATA	Creates a device data environment for the extent of the region. This feature is only available for ifx.
TARGET ENTER DATA	Specifies that variables are mapped to a device data environment. This feature is only available for ifx.
TARGET EXIT DATA	Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.
TARGET PARALLEL	Creates a device data environment in a parallel region and executes the construct on that device.
TARGET PARALLEL DO	Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.
TARGET PARALLEL DO SIMD	Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

TARGET PARALLEL LOOP	Specifies a shortcut for specifying a parallel loop inside a TARGET construct that contains no other statements than the parallel loop. This feature is only available for ifx.
TARGET SIMD	Specifies a TARGET construct that contains a SIMD construct and no other statement.
TARGET TEAMS	Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.
TARGET TEAMS DISTRIBUTE	Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.
TARGET TEAMS DISTRIBUTE PARALLEL DO	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.
TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.
TARGET TEAMS DISTRIBUTE SIMD	Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.
TARGET TEAMS LOOP	Specifies a shortcut for specifying a TEAMS LOOP construct inside a TEAMS construct that contains no other statements. This feature is only available for ifx.
TARGET UPDATE	Makes the list items in the device data environment consistent with their corresponding original list items. This feature is only available for ifx.
TASK	Defines a task region.
TASKGROUP	Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.
TASKLOOP	Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.
TASKLOOP SIMD	Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.
TASKWAIT	Specifies a wait on the completion of child tasks generated since the beginning of the current task.
TASKYIELD	Specifies that the current task can be suspended at this point in favor of execution of a different task.
TEAMS construct	Creates a group of thread teams to be used in a parallel region. This feature is only available for ifx.

TEAMS DISTRIBUTE	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.
TEAMS DISTRIBUTE PARALLEL DO	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
TEAMS DISTRIBUTE PARALLEL DO SIMD	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the primary threads of the teams region, which will be executed concurrently using SIMD instructions.
TEAMS DISTRIBUTE SIMD	Creates a league of thread teams to execute the structured block in the primary thread of each team. It also specifies a loop that will be distributed across the primary threads of the teams region. The loop will be executed concurrently using SIMD instructions.
TEAMS LOOP	Specifies a shortcut for specifying a LOOP construct inside a TEAMS construct. This feature is only available for ifx.
THREADPRIVATE	Makes named common blocks private to each thread, but global within the thread.
TILE	Tiles (or blocks) one or more loops in a loop nest. It is a pure directive. This feature is only available for ifx.
UNROLL	Partially or fully unrolls a DO loop. It is a pure directive. This feature is only available for ifx.
WORKSHARE	Divides the work of executing a block of statements or constructs into separate units.

The OpenMP Fortran directives can be grouped into categories. For more information about the categories for these directives, see Categories for OpenMP* Fortran Directives.

Categories for OpenMP* Fortran Directives

OpenMP* Fortran directives can be categorized as shown in the following tables.

Parallelism	OpenMP* Fortran Directive
Use this directive to form a team of threads and execute those threads in parallel.	PARALLEL

Use these directives for deferring execution.

Tasking	OpenMP* Fortran Directives
Use these directives for deferring execution.	TASK TASKLOOP

Worksharing	OpenMP* Fortran Directives
Use these directives to share work among a team of threads.	DO Directive LOOP Directive (ifx) SECTIONS SCOPE (ifx) SINGLE WORKSHARE

Synchronization	OpenMP* Fortran Directives
Use these directives to synchronize between threads.	ATOMIC BARRIER CRITICAL Directive FLUSH Directive MASKED (ifx) MASTER (deprecated, see MASKED) ORDERED TASKGROUP TASKWAIT TASKYIELD

Data Environment	OpenMP* Fortran Directives
Use these directives to affect the data environment.	DECLARE MAPPER (ifx) DEPOBJ (ifx) GROUPPRIVATE(ifx) PREFETCH DATA language extension (ifx) THREADPRIVATE

Offload Target Control	OpenMP* Fortran Directives
Use these directives to control execution on one or more offload targets.	DECLARE TARGET (ifx) DECLARE VARIANT (ifx) DISPATCH (ifx) DISTRIBUTE INTEROP (ifx) REQUIRES (ifx) TARGET Directive (ifx) TARGET DATA (ifx)

Offload Target Control	OpenMP* Fortran Directives
	TARGET ENTER DATA (ifx) TARGET EXIT DATA (ifx) TARGET UPDATE (ifx) TEAMS (ifx)

Vectorization	OpenMP* Fortran Directives
Use these directives to control execution on vector hardware.	DECLARE SIMD SCAN SIMD Directive (OpenMP*)

Loop Transformation	OpenMP* Fortran Directives
Use these directives to transform or restructure loops.	TILE (ifx) UNROLL (ifx)

Cancellation	OpenMP* Fortran Directives
Use these constructs to cancel an innermost enclosing region or to check if cancellation is in effect.	CANCEL CANCELLATION POINT

Memory Space Allocation	OpenMP* Fortran Directives
Use these declarative directives to allocate memory space.	ALLOCATE (ifx) ALLOCATORS (ifx)

User-Defined Reduction	OpenMP* Fortran Directive
Use this directive to declare a user-defined reduction operation.	DECLARE REDUCTION

Utility and Informational	OpenMP* Fortran Directives
Use these directives to get utility or informational data. Utility directives: These directives provide information that aids code readability, and may facilitate interactions with the implementation. Utility directives are informational unless an action time (AT) clause in an ERROR directive specifies EXECUTION; this makes the directive executable.	ASSUMES (ifx) ERROR (ifx) NOTHING (ifx)

Utility and Informational	OpenMP* Fortran Directives
Informational directives: These directives provide implementation information about properties of the code, which may aid in optimization.	

Metadirectives	OpenMP* Fortran Directive
Use this directive to conditionally select another directive.	METADIRECTIVE (ifx)

Combined and Composites	OpenMP* Fortran Directives
Combined directives: These are shortcuts for multiple directives in sequence. This kind of construct is a shortcut for specifying one construct immediately nested inside another construct. A combined construct is semantically identical to that of explicitly specifying the first construct containing one instance of the second construct and no other statements. Composite construct: These constructs are composed of two constructs but they do not have identical semantics to specifying one of the constructs immediately nested inside the other. This kind of construct either adds semantics not included in the constructs from which it is composed or the nesting of the one construct inside the other is not conforming.	DISTRIBUTE PARALLEL DO[1] DISTRIBUTE PARALLEL DO SIMD[1] DISTRIBUTE SIMD[1] DO SIMD[1] MASKED TASKLOOP (ifx) MASKED TASKLOOP SIMD (ifx) MASTER TASKLOOP (ifx) MASTER TASKLOOP SIMD (ifx) PARALLEL DO PARALLEL DO SIMD PARALLEL LOOP (ifx) PARALLEL MASKED (ifx) PARALLEL MASKED TASKLOOP (ifx) PARALLEL MASKED TASKLOOP SIMD (ifx) PARALLEL MASTER (ifx) PARALLEL MASTER TASKLOOP (ifx) PARALLEL MASTER TASKLOOP SIMD (ifx) PARALLEL SECTIONS PARALLEL WORKSHARE TARGET PARALLEL TARGET PARALLEL DO TARGET PARALLEL DO SIMD TARGET PARALLEL LOOP (ifx) TARGET SIMD TARGET TEAMS TARGET TEAMS DISTRIBUTE TARGET TEAMS DISTRIBUTE PARALLEL DO TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD TARGET TEAMS DISTRIBUTE SIMD TARGET TEAMS LOOP (ifx)

Combined and Composites	OpenMP* Fortran Directives
	TASKLOOP SIMD [1]
	TEAMS DISTRIBUTE
	TEAMS DISTRIBUTE PARALLEL DO
	TEAMS DISTRIBUTE PARALLEL DO SIMD
	TEAMS DISTRIBUTE SIMD
	TEAMS LOOP (ifx)

[1] This is a composite construct.

Clauses Used in Multiple OpenMP* Fortran Directives

This topic summarizes clauses that are used in more than one OpenMP* Fortran directive.

Other clauses (or keywords) are available for some OpenMP* Fortran directives. For more information, see each directive description.

Some of the OpenMP* Fortran directives have clauses (or options) you can specify to control the scope attributes of variables for the duration of the directive.

Data Scope Attribute Clauses

Name	Description
DEFAULT	Lets you specify a scope for all variables in the lexical extent of a parallel region.
FIRSTPRIVATE	Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.
IN_REDUCTION	Specifies that a task participates in a reduction.
LASTPRIVATE	Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.
LINEAR	Specifies that all variables in a list are private to a SIMD task and that they have a linear relationship within the iteration space of a loop.
PRIVATE	Declares one or more variables to be private to each thread in a team.
SHARED	Specifies variables that will be shared by all the threads in a team.

The data copying clauses let you copy data values from private or threadprivate variables in one implicit task or thread to the corresponding variables in other implicit tasks or threads in the team.

Data Copying Clauses

Name	Description
COPYIN	Specifies that the data in the primary thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.
COPYPRIVATE	Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.

The data motion clause MAP is used in OpenMP* Fortran TARGET directives. This data motion clause does not modify the values of any of the internal control variables (ICVs).

List items that appear in this data motion clause may have corresponding new list items created in the device data environment that is associated with the construct. If a new list item is created, a new list item of the same type, kind, and rank is allocated. The initial value of the new list item is undefined.

The original list items and new list items may share storage. This means that data races can occur. Data races are caused by unintended sharing of data; for example, when WRITEs to either item by one task or device are followed by a READ of the other item by another task or device without intervening synchronization.

Data Allocation and Data Mapping Clauses

Name	Description
ALLOCATE (ifx only)	Specifies the memory allocator to be used for one or more private variables or common blocks of a construct. This feature is only available for ifx.
MAP	Maps a variable from the data environment of the current task to the data environment of the device associated with the construct.

The following are other clauses that can be used in more than one OpenMP* Fortran directive.

Miscellaneous Clauses

Name	Description
ALIGNED	Specifies that all variables in a list are aligned.
COLLAPSE	Specifies how many loops are associated with the loop construct.
DEPEND	Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.
DEVICE	Specifies the target device for certain TARGET directives.
DEVICE_TYPE (ifx only)	Specifies whether a version of a procedure or a copy of a data entity is to be available on a HOST device, a non-HOST device, or both. This feature is only available for ifx.
FINAL	Specifies that the generated task will be a final task.

Name	Description
HINT	Specifies synchronization hints about a region to aid optimization.
IF	Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.
MERGEABLE	Specifies that the implementation may generate a merged task.
NOWAIT	Specifies that threads may resume execution before the execution of the region completes.
ORDER (ifx only)	Indicates that the iterations of the loop may execute in any order or simultaneously. For more information, see DO Directive, DISTRIBUTE, LOOP, and SIMD. This feature is only available for ifx.
PRIORITY	Specifies that the generated tasks have the indicated priority for execution.
REDUCTION	Performs a reduction operation on the specified variables.
SUBDEVICE (ifx only)	Specifies which tiles or compute slices (c-slices) of the offload device the offloaded code will run on. This feature is only available for ifx.
THREAD_LIMIT (ifx only)	Limits the number of threads that can participate in a construct. This feature is only available for ifx.
UNTIED	Specifies that the task is never tied to the thread that started its execution.

Conditional Compilation Rules

The OpenMP* Fortran API lets you conditionally compile Intel® Fortran statements if you use the appropriate directive prefix.

The prefix depends on which source form you are using, although `!$` is valid in all forms.

The prefix must be followed by a valid Intel Fortran statement on the same line.

Free Source Form

The free source form conditional compilation prefix is `!$`. This prefix can appear in any column as long as it is preceded only by white space. It must appear as a single word with no intervening white space. Free-form source rules apply to the directive line.

Initial lines must have a space after the prefix. Continued lines must have an ampersand as the last nonblank character on the line. Continuation lines can have an ampersand after the prefix with optional white space before and after the ampersand.

Fixed Source Form

For fixed source form programs, the conditional compilation prefix is one of the following: `!$`, `C$` (or `c$`), or `*$`.

The prefix must start in column one and appear as a single string with no intervening white space. Fixed-form source rules apply to the directive line.

After the prefix is replaced with two spaces, initial lines must have a space or zero in column six, and continuation lines must have a character other than a space or zero in column six. For example, the following forms for specifying conditional compilation are equivalent:

```
c23456789
!$    IAM = OMP_GET_THREAD_NUM( ) +
!$   *      INDEX
#IFDEF _OPENMP
      IAM = OMP_GET_THREAD_NUM( ) +
     *      INDEX
#ENDIF
```

Rules for Nesting and Binding

This section describes the dynamic nesting and binding rules for OpenMP* Fortran API directives.

Binding Rules

The following rules apply to dynamic binding:

- The DO, SECTIONS, SINGLE, MASKED, MASTER, and BARRIER directives bind to the dynamically enclosing PARALLEL directive, if one exists.
- The ORDERED directive binds to the dynamically enclosing DO directive.
- The ATOMIC directive enforces exclusive access with respect to ATOMIC directives in all threads, not just the current team.
- The CRITICAL directive enforces exclusive access with respect to CRITICAL directives in all threads, not just the current team.
- A directive can never bind to any directive outside the closest enclosing PARALLEL directive.

Nesting Rules

The following rules apply to dynamic nesting:

- A PARALLEL directive dynamically inside another PARALLEL directive logically establishes a new team, which is composed of only the current thread unless nested parallelism is enabled.
- DO, SECTIONS, and SINGLE directives that bind to the same PARALLEL directive are not allowed to be nested one inside the other.
- DO, SECTIONS, and SINGLE directives are not permitted in the dynamic extent of CRITICAL, MASKED, and MASTER directives.
- BARRIER directives are not permitted in the dynamic extent of DO, SECTIONS, SINGLE, MASKED, MASTER, and CRITICAL directives.
- MASKED and MASTER directives are not permitted in the dynamic extent of DO, SECTIONS, and SINGLE directives.
- ORDERED sections are not allowed in the dynamic extent of CRITICAL sections.
- Any directive set that is legal when executed dynamically inside a PARALLEL region is also legal when executed outside a parallel region. When executed dynamically outside a user-specified parallel region, the directive is executed with respect to a team composed of only the primary thread.

Examples

The following example shows nested PARALLEL regions:

```
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
        DO I =1, N
!$OMP PARALLEL SHARED(I,N)
!$OMP DO
        DO J =1, N
          CALL WORK(I,J)
        END DO
```

```
!$OMP END PARALLEL
      END DO
!$OMP END PARALLEL
```

Note that the inner and outer DO directives bind to different PARALLEL regions.

The following shows a variation of the preceding example:

```
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
        DO I =1, N
           CALL SOME_WORK(I,N)
        END DO
!$OMP END PARALLEL
      ...
      SUBROUTINE SOME_WORK(I,N)
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
        DO J =1, N
           CALL WORK(I,J)
        END DO
!$OMP END PARALLEL
        RETURN
        END
```

Equivalent Compiler Options

Some compiler directives and compiler options have the same effect, as shown in the table below. However, compiler directives can be turned on and off throughout a program, while compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

The following table shows compiler directives and equivalent command-line compiler options:

Compiler Directive	Equivalent Command-Line Compiler Option
DECLARE	`-warn declarations` (Linux*) `/warn:declarations` (Windows*)
NODECLARE	`-warn nodeclarations` (Linux) `/warn:nodeclarations` (Windows)
DEFINE *name*	`-D`*name* (Linux) `/D`*name* (Windows)
FIXEDFORMLINESIZE:*length*	`-extend-source` [*size*] (Linux) `/extend-source`[:*size*] (Windows)
FREEFORM	`-free` or `-nofixed` (Linux) `/free` or `/nofixed` (Windows)
NOFREEFORM	`-nofree` or `-fixed` (Linux) `/nofree` or `/fixed` (Windows)
INTEGER:*size*	`-integer_size`*size* (Linux) `/integer_size:`*size* (Windows)
OBJCOMMENT	`/libdir:user` (Windows)

Compiler Directive	Equivalent Command-Line Compiler Option
OPTIMIZE[: *n*]	`-On` (Linux) `/On` (Windows)
NOOPTIMIZE	`-O0` (Linux) `/Od` (Windows)
PACK:*alignment*	`-align` *recnbytes* (Linux) `/align:`*recnbytes* (Windows)
REAL:*size*	`-real-size`*size* (Linux) `/real-size:`*size* (Windows)
STRICT	`-warn stderrors` with `-stand f18` (Linux) `/warn:stderrors` with `/stand:f18` (Windows)
NOSTRICT	`-warn nostderrors` (Linux) `/warn:nostderrors` (Windows)

Scope and Association

Program entities are identified by names, labels, input/output unit numbers, operator symbols, or assignment symbols. For example, a variable, a derived type, or a subroutine is identified by its name.

Scope refers to the area in which a name is recognized. A scoping unit is the program or part of a program in which a name is defined or known. It can be any of the following:

- An entire executable program
- A single scoping unit
- A single statement (or part of a statement)

The region of the program in which a name is known and accessible is referred to as the scope of that name. These different scopes allow the same name to be used for different things in different regions of the program.

Association is the language concept that allows different names to refer to the same entity in a particular region of a program.

Scope

Program entities have the following kinds of scope (as shown in the table below):

- Global

  Entities that are accessible throughout an executable program. The name of a global entity must be unique. It cannot be used to identify any other global entity in the same executable program.
- Scoping unit (Local scope)

  Entities that are declared within a scoping unit. These entities are local to that scoping unit. The names of local entities are divided into classes (see the table below).

  A *scoping unit* is one of the following:

  - A derived-type definition
  - A procedure interface body (excluding any derived-type definitions and interface bodies contained within it)
  - A program unit or subprogram (excluding any derived-type definitions, interface bodies, and subprograms contained within it)

A scoping unit that immediately surrounds another scoping unit is called the host scoping unit. Named entities within the host scoping unit are accessible to the nested scoping unit by host association, unless access is blocked by an IMPORT ONLY or IMPORT NONE statement. For information about host association, see Use and Host Association.

Once an entity is declared in a scoping unit, its name can be used throughout that scoping unit. An entity declared in another scoping unit is a different entity even if it has the same name and properties.

Within a scoping unit, a local entity name that is not generic or an OpenMP* reduction identifier must be unique within its class. However, the name of a local entity in one class can be used to identify a local entity of another class.

Within a scoping unit, a generic name can be the same as any one of the procedure names in the interface block. A generic name can be the same as the name of a derived type.

An OpenMP* reduction identifier can be the same as any local entity name.

A component name has the same scope as the derived type of which it is a component. It can appear only within a component designator of a structure of that type.

For information on interactions between local and global names, see the table below.

- Statement

  Entities that are accessible only within a statement or part of a statement; such entities cannot be referenced in subsequent statements.

  The name of a statement entity can also be the name of a common block, or a local or construct variable accessible in the same scoping unit or construct; in this case, the name is interpreted within the statement as that of the statement entity.
- Construct

  Construct entities are accessible during the execution of the construct in which they are declared. Entities declared in the specification part of a BLOCK construct, associate names in ASSOCIATE, SELECT RANK, and SELECT TYPE constructs, and index variables in FORALL statements or constructs, or DO CONCURRENT constructs are construct entities. An index name of an inner FORALL statement or construct, or of a DO CONCURRENT construct cannot be the same as that of an index variable of an outer (containing) FORALL or DO CONCURRENT construct.

  An associate name of a SELECT TYPE construct has a different scope for each block of the construct; the declared type, dynamic type, type parameters, rank or bounds may differ from block to block. An associate name for a SELECT RANK construct has a different scope for each block of the construct since the rank of the associate name is different in each block. An associate name for an ASSOCIATE construct has the scope of the ASSOCIATE construct.

Scope of Program Entities

Entity	Scope	
Program units	Global	
Common blocks[1]	Global	
External procedures	Global	
Intrinsic procedures	Global[2]	
Module procedures	Local	Class I
Internal procedures	Local	Class I
Dummy procedures	Local	Class I
Statement functions	Local	Class I
Derived types	Local or construct	Class I
Components of derived types	Local	Class II

Entity	Scope	
Named constants	Local or construct	Class I
Named constructs	Local or construct	Class I
Namelist group names	Local	Class I
OpenMP* reduction identifier	Local	Class I
Generic identifiers	Local or construct	Class I
Argument keywords in procedures	Local	Class III
Variables	Local or construct	Class I
Variables that are dummy arguments in statement functions	Statement	
DO variables in an implied-DO list[3] of a DATA statement, or an array constructor	Statement	
DO index variables of a FORALL statement or construct, or a DO CONCURRENT construct	Construct	
Associate names	Construct	
Intrinsic operators	Global	
Defined operators	Local or construct	
Statement labels	Local	
External I/O unit numbers	Global	
Intrinsic assignment	Global[4]	
Defined assignment	Local or construct	

[1] Names of common blocks can also be used to identify local entities.

[2] If an intrinsic procedure is not used in a scoping unit, its name can be used as a local entity within that scoping unit. For example, if intrinsic function COS is not used in a program unit, COS can be used as a local variable there.

[3] The DO variable in an implied-DO list of an I/O list has local scope.

[4] The scope of the assignment symbol (=) is global, but it can identify additional operations (see Defining Generic Assignment).

Scoping units can contain other scoping units. For example, the following shows six scoping units:

```
MODULE MOD_1                    ! Scoping unit 1
   ...                          ! Scoping unit 1
CONTAINS                        ! Scoping unit 1
  FUNCTION FIRST                !   Scoping unit 2
    TYPE NAME                   !     Scoping unit 3
    ...                         !     Scoping unit 3
    END TYPE NAME               !     Scoping unit 3
    ...                         !   Scoping unit 2
  CONTAINS                      !   Scoping unit 2
    SUBROUTINE SUB_B            !       Scoping unit 4
      TYPE PROCESS              !         Scoping unit 5
```

```
      ...                          !         Scoping unit 5
      END TYPE PROCESS             !         Scoping unit 5
      INTERFACE                    !         Scoping unit 5
        SUBROUTINE SUB_A           !           Scoping unit 6
        ...                        !           Scoping unit 6
          BLOCK                    !             Scoping unit 7
          ...                      !             Scoping unit 7
          END BLOCK                !             Scoping unit 7
        END SUBROUTINE SUB_A       !           Scoping unit 6
      END INTERFACE                !         Scoping unit 5
    END SUBROUTINE SUB_B           !       Scoping unit 4
  END FUNCTION   FIRST             !   Scoping unit 2
END MODULE                         ! Scoping unit 1
```

Unambiguous Generic Procedure References

When a generic procedure reference is made, a specific procedure is invoked. If the following rules are used, the generic reference will be unambiguous:

- Two dummy arguments are said to be distinguishable if any of the following are true:
  - One is a procedure and the other is a data object.
  - One has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN).
  - They are both data objects or both known to be functions, and they have different type and kind parameters, or different rank.
  - One is a function with non-zero rank and the other is not known to be a function.
- Within a scoping unit, two procedures that have the same generic name must both be subroutines or both be functions. One of the procedures must have a non-optional dummy argument that is one of the following:
  - Not present by position or argument keyword in the other argument list
  - Is present, but is distinguishable from the dummy argument in the other argument list
- Within a scoping unit, two procedures that have the same generic operator must both have the same number of arguments or both define assignment.

  One of the procedures must have a dummy argument that corresponds, by position in the argument list, to a dummy argument of the other procedure. The dummy arguments must be distinguishable from each other in each argument list.

When an interface block extends an intrinsic procedure, operator, or assignment, the rules apply as if the intrinsic consists of a collection of specific procedures, one for each allowed set of arguments.

When a generic procedure is accessed from a module, the rules apply to all the specific versions, even if some of them are inaccessible by their specific names.

Defining Generic Names for Procedures for details on generic procedure names

Resolve Procedure References

The procedure name in a procedure reference is either established to be generic or specific, or is not established. The rules for resolving a procedure reference differ depending on whether the procedure is established and how it is established.

References to Generic Names

Within a scoping unit, a procedure name is established to be generic if any of the following is true:

- The scoping unit contains an interface block with that procedure name.
- The procedure name matches the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is established to be generic in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be generic in a host scoping unit.

To resolve a reference to a procedure name established to be generic, the following rules are used in the order shown:

1. If an interface block with that procedure name appears in one of the following, the reference is to the specific procedure providing that interface:
   a. The scoping unit that contains the reference
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with one of the specific interfaces of the interface block.
2. If the procedure name is specified with the INTRINSIC attribute in one of the following, the reference is to that intrinsic procedure:
   a. The same scoping unit
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with the interface of that intrinsic procedure.
3. If the following is true, the reference is resolved by applying rules 1 and 2 to the host scoping unit:
   a. The procedure name is established to be generic in the host scoping unit
   b. There is agreement between the scoping unit and the host scoping unit as to whether the procedure is a function or subroutine name.
4. If none of the preceding rules apply, the reference must be to the generic intrinsic procedure with that name. The reference must be consistent with the interface of that intrinsic procedure.

Examples

The following example shows how a module can define three separate procedures and give them a generic name DUP through an interface block. Although the main program calls all three by the generic name, there is no ambiguity since the arguments are of different data types, and DUP is a function rather than a subroutine. The module UN_MOD must give each procedure a different name.

```
MODULE UN_MOD
!

CONTAINS
   subroutine dup1(x,y)
   real x,y
   print *, ' Real arguments', x, y
   end subroutine dup1

   subroutine dup2(m,n)
   integer m,n
```

```
   print *, ' Integer arguments', m, n
   end subroutine dup2

   character function dup3 (z)
   character(len=2) z
   dup3 = 'String argument '// z
   end function dup3

END MODULE

program unclear
!
! shows how to use generic procedure references

USE UN_MOD
INTERFACE DUP
   MODULE PROCEDURE dup1, dup2, dup3
END INTERFACE

real a,b
integer c,d
character (len=2) state

a = 1.5
b = 2.32
c = 5
d = 47
state = 'WA'

call dup(a,b)
call dup(c,d)
print *, dup(state)       !actual output is 'S' only
END
```

Note that the function DUP3 only prints one character, since module UN_MOD specifies no length parameter for the function result.

If the dummy arguments x and y for DUP were declared as integers instead of reals, then any calls to DUP would be ambiguous. If this is the case, a compile-time error results.

The subroutine definitions, DUP1, DUP2, and DUP3, must have different names. The generic name is specified in the first line of the interface block, and in the example is DUP.

References to Specific Names

In a scoping unit, a procedure name is established to be specific if it is not established to be generic and any of the following is true:

- The scoping unit contains an interface body with that procedure name.
- The scoping unit contains an internal procedure, module procedure, or statement function with that procedure name.
- The procedure name is the same as the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is specified with the EXTERNAL attribute in that scoping unit.
- The procedure name is established to be specific in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be specific in a host scoping unit.

To resolve a reference to a procedure name established to be specific, the following rules are used in the order shown:

1. If either of the following is true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram, and it contains an interface body with that procedure name.
   b. The procedure name has been declared EXTERNAL, and the procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.
2. If the scoping unit contains an interface body or the procedure name has been declared EXTERNAL, and Rule 1 does not apply, the reference is to an external procedure with that name.
3. If the scoping unit contains an internal procedure or statement function with that procedure name, the reference is to that entity.
4. If the procedure name has been declared INTRINSIC in the scoping unit, the reference is to the intrinsic procedure with that name.
5. If the scoping unit contains a USE statement that makes the name of a module procedure accessible, the reference is to that procedure. Since the USE statement allows renaming, the name referenced may differ from the name of the module procedure.)
6. If none of the preceding rules apply, the reference is resolved by applying these rules to the host scoping unit.

References to Non-Established Names

In a scoping unit, a procedure name is not established if it is not determined to be generic or specific.

To resolve a reference to a procedure name that is not established, the following rules are used in the order shown:

1. If both of the following are true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram.
   b. The procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.
2. If both of the following are true, the procedure is an intrinsic procedure and the reference is to that intrinsic procedure:
   a. The procedure name matches the name of an intrinsic procedure.
   b. There is agreement between the intrinsic procedure definition and the reference of the name as a function or subroutine.
3. If neither of the preceding rules apply, the reference is to an external procedure with that name.

Association

Association allows different program units to access the same value through different names. Entities are associated when each is associated with the same storage location.

This section discusses the forms of association.

Name Association

Name association allows an entity to be accessed from different scoping units by the same name or by different names.

This section discusses the forms of name association.

To see an example of Name, Pointer, and Storage Association, see Storage Association.

Argument Association

Arguments are the values passed to and from functions and subroutines through calling program argument lists.

Execution of a procedure reference establishes argument association between an actual argument and its corresponding dummy argument. The name of a dummy argument can be different from the name of its associated actual argument (if any).

When the procedure completes execution, the argument association is terminated. A dummy argument of that procedure can be associated with an entirely different actual argument in a subsequent invocation of the procedure.

Association Between Actual Arguments and Dummy Data Objects

A scalar dummy argument of a non-elemental procedure can be associated only with a scalar actual argument.

If the actual argument is scalar, the corresponding dummy argument must be scalar unless the actual argument is one of the following:

- Of type default character
- Of type character with the C character kind
- An element or substring of an element of an array that is not an assumed-shape or pointer array

If the procedure is non-elemental and is referenced by a generic name or as a defined operator or defined assignment, the ranks of the actual arguments and corresponding dummy arguments must agree.

If a scalar dummy argument is of type default character, the length of the dummy argument must be less than or equal to the length of the actual argument. The dummy argument becomes associated with the leftmost *len* characters of the actual argument. If an array dummy argument is of type default character and is not assumed shape, it becomes associated with the leftmost characters of the actual argument element sequence and it must not extend beyond the end of that sequence.

If a dummy argument is not allocatable and is not a pointer, it must be type compatible with the associated actual argument. If a dummy argument is allocatable or a pointer, the associated actual argument must be polymorphic only if the dummy argument is polymorphic, and the declared type of the actual argument must be the same as the declared type of the dummy argument.

If the dummy argument is a pointer, the actual argument must be a pointer and the non-deferred type parameters and ranks must agree. If a dummy argument is allocatable, the actual argument must be allocatable and the non-deferred type parameters and ranks must agree. The actual argument can have an allocation status of unallocated.

At the invocation of the procedure, the pointer association status of an actual argument associated with a pointer dummy argument becomes undefined if the dummy argument has INTENT(OUT).

The dynamic type of a polymorphic, allocatable, or pointer dummy argument can change as a result of execution of an allocate statement or pointer assignment in the subprogram. Because of this behavior, the corresponding actual argument needs to be polymorphic and have a declared type that is the same as the declared type of the dummy argument, or an extension of that type.

The values of assumed type parameters of a dummy argument are assumed from the corresponding type parameters of the associated actual argument.

Except in references to intrinsic inquiry functions, if the dummy argument is not a pointer and the corresponding actual argument is a pointer, the actual argument must be associated with a target and the dummy argument becomes the argument associated with that target.

Except in references to intrinsic inquiry functions, if the dummy argument is not allocatable and the actual argument is allocatable, the actual argument must be allocated.

If the dummy argument has the VALUE attribute, it becomes associated with a definable anonymous data object whose initial value is that of the actual argument. Subsequent changes to the value or definition status of the dummy argument do not affect the actual argument.

If the dummy argument does not have the TARGET or POINTER attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument on invocation of the procedure.

If the dummy argument has the TARGET attribute, does not have the VALUE attribute, is either a scalar or an assumed-shape array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, then the following is true:

- Any pointers associated with the actual argument become associated with the corresponding dummy argument on invocation of the procedure.
- When execution of the procedure completes, any pointers that do not become undefined and are associated with the dummy argument remain associated with the actual argument.

Any pointers associated with the dummy argument become undefined when execution of the procedure completes in these cases:

- If the dummy argument has the TARGET attribute and the corresponding actual argument does not have the TARGET attribute or it is an array section with a vector subscript.
- If the dummy argument has the TARGET attribute and the VALUE attribute.

If a non-pointer dummy argument has INTENT (OUT) or INTENT (INOUT), the actual argument must be definable. If a dummy argument has INTENT (OUT), the corresponding actual argument becomes undefined at the time the association is established, except for components of an object of derived type for which default initialization has been specified. If the dummy argument is not polymorphic and the type of the actual argument is an extension of the type of the dummy argument, only the part of the actual argument that is of the same type as the dummy argument becomes undefined.

Association Between Actual Arguments and Dummy Procedure Entities

If a dummy argument is a procedure pointer, the associated actual argument must be a procedure pointer, a reference to a function that returns a procedure pointer, or a reference to the NULL intrinsic function.

If a dummy argument is a dummy procedure without the POINTER attribute, the associated actual argument must be the specific name of an external, module, dummy, or intrinsic procedure, an associated procedure pointer, or a reference to a function that returns an associated procedure pointer. If the specific name is also a generic name, only the specific procedure is associated with the dummy argument.

For generic declarations, a dummy argument is type, kind, and rank compatible with another dummy argument if following is true:

- The first is type compatible with the second.
- The kind type parameters of the first have the same values as the corresponding kind type parameters of the second.
- Both have the same rank or either one is assumed-rank.

If an external procedure name or a dummy procedure name is used as an actual argument, its interface must be explicit or it must be explicitly declared to have the EXTERNAL attribute.

If the interface of the dummy argument is explicit, the procedure characteristics must be the same for the associated actual argument and the corresponding dummy argument, except that a pure actual argument can be associated with a dummy argument that is not pure, and an elemental intrinsic actual procedure can be associated with a dummy procedure that is prohibited from being elemental.

If the interface of the dummy argument is implicit and either the name of the dummy argument is explicitly typed or it is referenced as a function, the dummy argument must not be referenced as a subroutine and the actual argument must be a function, function procedure pointer, or dummy procedure.

If the interface of the dummy argument is implicit and a reference to it appears as a subroutine reference, the actual argument must be a subroutine, subroutine procedure pointer, or dummy procedure.

An assumed-rank dummy argument can correspond to an actual argument of any rank. If the actual argument has rank zero (is a scalar), the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including the lack of a final extent in the case of an assumed-size array. If the actual argument is an array and the dummy argument is allocatable or a pointer, the bounds of the dummy argument are assumed from the actual argument.

An assumed-type dummy argument must not correspond to an actual argument that is of a derived type that has type parameters, type-bound procedures, or final subroutines.

Association For C Interoperability

When a Fortran procedure that has an INTENT(OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated upon entry to the Fortran procedure.

When a C function is invoked from a Fortran procedure by means of an interface with an INTENT(OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

Procedure Characteristics

Use and Host Association

Use association allows the entities in a module to be accessible to other scoping units. *Host association* allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program.

Use association and host association remain in effect throughout the execution of the executable program.

An interface body does not access named entities by host association, but it can access entities by use association.

Example

The following example shows host and use association:

```
MODULE SHARE_DATA
  REAL Y, Z
END MODULE

PROGRAM DEMO
  USE SHARE_DATA         ! All entities in SHARE_DATA are available
  REAL B, Q              !   through use association.
  ...
  CALL CONS (Y)
CONTAINS
  SUBROUTINE CONS (Y)    ! Y is a local entity (dummy argument).
    REAL C, Y
    ...
    Y = B + C + Q + Z    ! B and Q are available through host association.
    ...                  !   C is a local entity, explicitly declared.
  END SUBROUTINE CONS    !   is available through use association.
END PROGRAM DEMO
```

Scope for details on entities with local scope

Use Association

Use association allows the entities in a module to be accessible to other scoping units. This association remains in effect throughout the execution of the program. The mechanism for use association is the USE statement. The USE statement provides access to all public entities in the module, unless ONLY is specified. In this case, only the entities named in the ONLY list can be accessed.

If an entity that is accessed by use association has the same non-generic name as a host entity, the host entity is inaccessible. A name that appears in the scoping unit as an external name in an EXTERNAL statement is a global name, and any entity of the host that has this as its non-generic name is inaccessible.

For more information on rules that apply to use association, see the USE statement.

See Also

USE statement

Host Association

Scope for details on entities with local scope

Host Association

Host association allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program. This association remains in effect throughout the execution of the program.

The following also have access to entities from its host:

- A module procedure interface body
- A derived-type definition
- An interface body that is not a separate interface body has access to the named entities from its host that are made accessible by IMPORT statements in the interface body.

The accessed entities are known by the same name and have the same attributes as in the host, except that a local entity can have the ASYNCHRONOUS attribute even if the host entity does not, and a non-coarray local entity can have the VOLATILE attribute even if the host entity does not. The accessed entities can be named data objects, derived types, abstract interfaces, procedures, generic identifiers, and NAMELIST groups.

Entities that are local to a procedure are not accessible to their hosts.

The following are considered local identifiers within a scoping unit so they are not accessible to their hosts:

- A function name in a statement function, an entity declaration in a type declaration statement, or the name of an entity declared by an interface body, unless any of these are global identifiers.
- An object name in an entity declaration in a type declaration statement or a POINTER, SAVE, ALLOCATABLE, or TARGET statement.
- A type name in a derived type statement.
- A procedure pointer that has the EXTERNAL attribute.
- The name of a variable that is wholly or partially initialized in a DATA statement.
- The name of an object that is wholly or partially initialized in an EQUIVALENCE statement.
- A NAMELIST group name in a NAMELIST statement.
- A generic name in a generic specification in an INTERFACE statement.
- The name of a named construct.
- The name of a dummy argument in a FUNCTION, SUBROUTINE, or ENTRY statement, or a statement function.
- A named constant defined in a PARAMETER statement.
- An array name in a DIMENSION statement.
- A variable name in a common block object in a COMMON statement.
- A result name in a FUNCTION or ENTRY statement.
- An intrinsic procedure name in an INTRINSIC statement.

A name that appears in an ASYNCHRONOUS or VOLATILE statement is not necessarily the name of a local variable. In an internal or module procedure, if a variable that is accessible via host association is specified in an ASYNCHRONOUS or VOLATILE statement, that host variable is given the ASYNCHRONOUS or VOLATILE attribute in the local scope.

If an intrinsic procedure is accessed by means of host association, it must be established to be intrinsic in the host scoping unit by one of the following methods:

- It must be explicitly given the INTRINSIC attribute.
- It must be invoked as an intrinsic procedure.
- It must be accessed from a module or from its host where it is established to be intrinsic.

If a procedure gains access to a pointer by host association, the association of the pointer with a target that is current at the time the procedure is invoked remains current within the procedure. This pointer association can be changed within the procedure. After execution of the procedure, the pointer association remains current, unless the execution caused the target to become undefined. If this occurs, the host associated pointer becomes undefined.

NOTE
Implicit declarations can cause problems for host association. It is recommended that you use IMPLICIT NONE in both the host and the contained procedure, and that you explicitly declare all entities.

When all entities are explicitly declared, local declarations override host declarations, and host declarations that are not overridden are available in the contained procedure.

Examples

The following example shows how a host and an internal procedure can use host-associated entities:

```
program INTERNAL
! shows use of internal subroutine and CONTAINS statement
   real a,b,c
   call find
   print *, c
contains
   subroutine find
     read *, a,b
     c = sqrt(a**2 + b**2)
   end subroutine find
end
```

In this case, the variables `a`, `b`, and `c` are available to the internal subroutine `find` through host association. They do not have to be passed as arguments to the internal procedure. In fact, if they are, they become local variables to the subroutine and hide the variables declared in the host program.

Conversely, the host program knows the value of `c`, when it returns from the internal subroutine that has defined `c`.

Scope for details on entities with local scope

Linkage Association

Linkage association occurs between the following:

- A module variable that has the BIND attribute and the C variable with which it interoperates
- A Fortran common block and the C variable with which it interoperates

This association remains in effect throughout the execution of the program.

See Also
USE statement
Host Association
Scope for details on entities with local scope

Construct Association

Construct association establishes an association between each selector and the corresponding associate name of an ASSOCIATE, CHANGE TEAM, SELECT RANK, or SELECT TYPE construct.

If the selector is allocatable, it must be allocated. The associate name is associated with the data object and does not have the ALLOCATABLE attribute.

If the selector has the POINTER attribute, it must be associated. The associate name is associated with the target of the pointer and does not have the POINTER attribute; it has the TARGET attribute if the selector is a variable that has the POINTER or TARGET attribute.

If the selector has the ASYNCHRONOUS or VOLATILE attribute, the entity associated with the corresponding associate name also has that attribute. If the selector is polymorphic, the associated entity has the same dynamic type and type parameters as the selector. If the selector has the OPTIONAL attribute, it must be present. If the selector is contiguous, the associated entity is also contiguous.

If the selector is a variable other than an array section having a vector subscript, the association is with the data object specified by the selector; otherwise, the association is with the value of the selector expression, which is evaluated before the execution of the block.

Each associate name remains associated with the corresponding selector throughout the execution of the executed block. Within the block, each selector is known by, and can be accessed by, the corresponding associate name. When the construct is terminated, the association is terminated.

See Also
USE statement
Host Association
Scope for details on entities with local scope

Additional Attributes of Associate Names

In an ASSOCIATE, CHANGE TEAM, or SELECT TYPE construct, the rank of each entity identified by an associate name has the same rank as its corresponding selector. The lower bound of each dimension is the result of the intrinsic function LBOUND applied to the corresponding dimension of selector. The upper bound of each dimension is one less than the sum of the lower bound and the extent.

Each entity identified by an associate name in an ASSOCIATE, SELECT RANK, or SELECT TYPE construct has the same corank as the corresponding selector. The cobounds of each codimension of the entity are the same as those of the selector. In a CHANGE TEAM construct, the entity identified by an associate name is a coarray, with coshape and cobounds as specified in its codimension declaration.

The associated entity is a variable; it is not definable if the selector is not definable. An associate name or a subobject of the associate name is not allowed in a variable definition context or a pointer association context if the selector is not allowed in a variable definition context.

In a SELECT RANK construct, the selector has assumed rank, and assumed rank entities are not otherwise definable. However, in the block following a RANK(*) statement the associate name is the name of a one dimensional assumed-size array, and in the block following a RANK (*scalar-int-const-expr*), the variable has the specified rank. In these cases, if the selector is otherwise definable ignoring that it is assumed rank, the associated entity may be defined or undefined.

Pointer Association

A pointer can be associated with a target. At different times during the execution of a program, a pointer can be undefined, associated with different targets, or be disassociated. The initial association status of a pointer is undefined. A pointer can become associated by the following:

- Pointer assignment (pointer => target)

  The target must be associated, or specified with the TARGET attribute. If the target is allocatable, it must be currently allocated.
- Allocation (successful execution of an ALLOCATE statement)

  The ALLOCATE statement must reference the pointer.

A pointer becomes disassociated if any of the following occur:

- The pointer is nullified by a NULLIFY statement.
- The pointer is deallocated by a DEALLOCATE statement.
- The pointer is assigned a disassociated pointer or the NULL intrinsic function.
- The pointer is an ultimate component of an object of a type for which default initialization is specified for the component and one of the following is true:
  - A procedure is invoked with this object as an actual argument corresponding to a non-pointer, non-allocatable, dummy argument with INTENT (OUT).
  - A procedure is invoked with this object as an unsaved, non-pointer, non-allocatable local object that is not accessed by use or host association.
  - This object is allocated.

When a pointer is associated with a target, the definition status of the pointer is defined or undefined, depending on the definition status of the target. A target is undefined in the following cases:

- If it was never allocated
- If it is not deallocated through the pointer
- If a RETURN or END statement causes it to become undefined

If a pointer is associated with a definable target, the definition status of the pointer can be defined or undefined, according to the rules for a variable.

The association status of a pointer becomes undefined when a DO CONCURRENT construct is terminated and the pointer's association status was changed in more than one iteration of the construct.

If the association status of a pointer is disassociated or undefined, the pointer must not be referenced or deallocated.

Whatever its association status, a pointer can always be nullified, allocated, or associated with a target. When a pointer is nullified, it is disassociated. When a pointer is allocated, it becomes associated, but is undefined. When a pointer is associated with a target, its association and definition status are determined by its target.

To see an example of Name, Pointer, and Storage Association, see Storage Association.

Storage Association

Storage association describes the relationships that exist among data objects. It is the association of two or more data objects that occurs when two or more storage sequences share, or are aligned with, one or more *storage units*. Storage sequences are used to describe relationships among variables, common blocks, and result variables.

Example

The following shows an example of Name, Pointer, and Storage association:

```
! Scoping Unit 1: An external program unit

REAL A, B(4)
REAL, POINTER :: M(:)
REAL, TARGET :: N(12)
COMMON /COM/...
EQUIVALENCE (A, B(1))        ! Storage association between A and B(1)
M => N                       ! Pointer association
CALL P (actual-arg,...)
...

! Scoping Unit 2: An external procedure
SUBROUTINE P (dummy-arg,...)  ! Name and storage association between
                              !    these arguments and the calling
                              !    routine's arguments in scoping unit 1
  COMMON /COM/...             ! Storage association with common block COM
                              !    in scoping unit 1

  REAL Y
  CALL Q (actual-arg,...)
  CONTAINS
    SUBROUTINE Q (dummy-arg,...) ! Name and storage association
between
                                 !   these arguments and the calling
                                 !   routine's arguments in host procedure
                                 !   P (subprogram Q has host association
                                 !   with procedure P)
      Y = 2.0*(Y-1.0)       ! Name association with Y in host procedure P
    ...
```

Storage Units and Storage Sequence

A *storage unit* is a fixed unit of physical memory allocated to certain data. A *storage sequence* is a sequence of storage units. The size of a storage sequence is the number of storage units in the storage sequence. A storage unit can be numeric, character, or unspecified.

A non-pointer scalar of type default real, integer, or logical occupies one numeric storage unit. A non-pointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel® Fortran, one numeric storage unit corresponds to 4 bytes of memory.

A non-pointer scalar of type default character with character length 1 occupies one character storage unit. A non-pointer scalar of type default character with character length *len* occupies *len* contiguous character storage units. In Intel® Fortran, one character storage unit corresponds to 1 byte of memory.

A non-pointer scalar of nondefault data type occupies a single unspecified storage unit. The number of bytes corresponding to the unspecified storage unit differs depending on the data type.

The following table lists the storage requirements (in bytes) for the intrinsic data types:

Data Type Storage Requirements

Data Type	Storage Requirements (in bytes)
BYTE	1
LOGICAL	2, 4, or 8 [1]
LOGICAL(1)	1

Data Type	Storage Requirements (in bytes)
LOGICAL(2)	2
LOGICAL(4)	4
LOGICAL(8)	8
INTEGER	2, 4, or 8 [1]
INTEGER(1)	1
INTEGER(2)	2
INTEGER(4)	4
INTEGER(8)	8
REAL	4, 8, or 16[2]
REAL(4)	4
DOUBLE PRECISION	8
REAL(8)	8
REAL(16)	16
COMPLEX	8, 16, or 32[2]
COMPLEX(4)	8
DOUBLE COMPLEX	16
COMPLEX(8)	16
COMPLEX(16)	32
CHARACTER	1
CHARACTER*len	len [3]
CHARACTER*(*)	assumed-length [4]

[1] Depending on default integer, LOGICAL and INTEGER can have 2, 4, or 8 bytes. The default allocation is four bytes.

[2] Depending on default real, REAL can have 4, 8, or 16 bytes and COMPLEX can have 8, 16, or 32 bytes. The default allocations are four bytes for REAL and eight bytes for COMPLEX.

[3] The value of len is the number of characters specified. The largest valid value is 2**63-1 on Intel® 64 architecture; 2**31-1 on IA-32 architecture. Negative values are treated as zero.

[4] The assumed-length format *(*) applies to dummy arguments, PARAMETER statements, or character functions, and indicates that the length of the actual argument or function is used. (See Assumed-Length Character Arguments.)

A non-pointer scalar of sequence derived type occupies a sequence of storage sequences corresponding to the components of the structure, in the order they occur in the derived-type definition. Note that a sequence derived type has a SEQUENCE statement.

A pointer occupies a single unspecified storage unit that is different from that of any non-pointer object and is different for each combination of type, type parameters, and rank.

The definition status and value of a data object affects the definition status and value of any storage-associated entity.

When two objects occupy the same storage sequence, they are totally storage-associated. When two objects occupy parts of the same storage sequence, they are partially associated. An EQUIVALENCE statement, a COMMON statement, or an ENTRY statement can cause total or partial storage association of storage sequences.

Assumed-Length Character Arguments
COMMON
ENTRY
EQUIVALENCE

Array Association

A non-pointer array occupies a sequence of contiguous storage sequences, one for each array element, in array element order.

Two or more arrays are associated when each one is associated with the same storage location. They are partially associated when part of the storage associated with one array is the same as part or all of the storage associated with another array.

If arrays with different data types are associated, or partially associated, with the same storage location, and the value of one array is defined (for example, by assignment), the value of the other array becomes undefined. This happens because an element of an array is considered defined only if the storage associated with it contains data of the same type as the array name.

An array element, array section, or whole array is defined by a DATA statement before program execution. Note that the array properties must be declared in a previous specification statement. During program execution, array elements and sections are defined by an assignment or input statement, and entire arrays are defined by input statements.

Arrays
DATA statement
Array Elements for details on array element order

Inheritance Association

Inheritance association occurs between components of a parent component and components inherited by type extension into an extended type.

This association is not affected by the accessibility of the inherited components.

Example

The following example shows inheritance association:

```
TYPE POINT                  ! A base type
REAL :: X, Y
END TYPE POINT

TYPE, EXTENDS(POINT) :: COLOR_POINT   ! An extension of TYPE(POINT)
                                      ! Components X and Y, and component name POINT,
                                      !   are inherited from the parent type POINT
INTEGER :: COLOR
END TYPE COLOR_POINT
```

Deleted and Obsolescent Language Features

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 features, and identified some Fortran 90 language features to be obsolescent.

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 obsolescent features, and identified some Fortran 90 language features to become obsolescent. Subsequent standard revisions have continued to identify some features of previous standards as obsolescent and to delete selected features that were previously deemed obsolescent.

Fortran 2008 has also identified some earlier standard language features to be obsolescent. Features considered obsolescent may be removed from future revisions of the Fortran Standard.

Fortran 2018 identified the following language features as obsolescent: the COMMON and EQUIVALENCE statement, the FORALL statement and construct, BLOCK DATA subprograms, labeled DO loops, and specific names for intrinsic procedures. The arithmetic IF statement and the non-block form of DO constructs were deleted in Fortran 2018.

Fortran 2023 does not identify any additional obsolescent or deleted features.

To have these features flagged, you can specify compiler option `stand`.

NOTE
Intel® Fortran fully supports features identified as deleted from or obsolescent in the Fortran Standard.

See Also
stand compiler option

Deleted Language Features in the Fortran Standard

Some language features, considered redundant in older versions of the Fortran Standard, are not included in the current Fortran Standard. However, they are still fully supported by Intel® Fortran.

In the examples below, both forms are supported by Intel® Fortran, but the Fortran 2018 Standard only supports the second form:

- ASSIGN and assigned GO TO statements

  The ASSIGN statement, when assigning a label for use with the assigned GO TO statement, can be replaced by assigning the integer value of the label to an integer variable; the assigned GO TO statement can then be replaced by an IF statement that tests the integer variable for various values and then goes to the label that represents that value. For example, replace:

```
ASSIGN 10 TO J
...
ASSIGN 20 TO J
...
GO TO J
```

  with:

```
J = 10
...
J = 20
...
IF (J .EQ. 10) THEN
    GO TO 10
ELSE IF (J .EQ. 20) THEN
    GO TO 20
END IF
```

- Arithmetic IF statement

  The arithmetic IF statement can be replace by an IF-THEN-ELSE construct or a CASE SELECT construct.

For example, replace:

```
IF (expr) 10, 20, 30
```

with:

```
IF (expr .LT. 0) THEN
  GO TO 10
ELSE IF (expr .EQ. 0) THEN
  GO TO 20
ELSE
  GO TO 30
ENDIF
```

- Assigned FORMAT specifier

  The assigned FORMAT specifier sets an integer variable to the label of a FORMAT statement and then the integer variable is used in an I/O statement instead of the FORMAT label. You can replace the integer variable with a character variable whose value is the contents of the FORMAT statement, and then use the character variable in the I/O statement as the format. For example, replace:

```
ASSIGN 1000 TO IFMT
...
WRITE (6, IFMT) X, Y
...
1000     FORMAT (2E10.2)
```

  with:

```
CHARACTER(20) :: IFMT = "(2E10.2)"
...
WRITE (6, IFMT) X, Y
```

- The non-block form of a DO statement

  The non-block form of a DO loop contains a statement label in the DO statement identifying the terminal statement of the DO. The terminal statement may be an executable statement and may be shared with another non-block DO statement. Use an END DO statement as the terminal statement for each DO loop.

  You should not use statement labels on the terminating statement and in the DO statement, because labeled DO loops are now obsolescent.

  For example, replace the following:

```
   DO 10 I = 1, N
     DO 10 J = 1, M
10 A(I, J) = F_OF (I, J)
```

  with this:

```
DO I = 1, N
  DO J = 1, M
    A(I, J) = F_OF (I, J)
  END DO
END DO
```

- Branching to an END IF statement from outside its IF block

  The END IF statement can no longer be a target of a GO TO statement that is outside the IF block that ends with that END IF statement. Use a CONTINUE statement after the END IF as the target of the GO TO statement. For example, replace:

```
IF ...
    GO TO 100
ELSE IF ...
100  END IF
```

with:

```
IF ...
     GO TO 100
ELSE IF ...
END IF
100  CONTINUE
```

- H edit descriptor

  Replace the H edit descriptor of the form *n*H*characters* with "*characters*". Remember to double any quotes or apostrophes in the string *characters*.
- PAUSE statement

  The PAUSE statement displays a character string on the standard output device and then suspends program execution until any character is typed on the standard input device. You can replace the PAUSE statement with a WRITE statement followed by a READ statement. For example, replace:

```
PAUSE " don't forget to buy milk"
```

  with:

```
WRITE (6, *) " don't forget to buy milk"
READ (5, *)    ! no io-list is necessary, the input is ignored
```

- Real and double precision DO control variables and DO loop control expressions

  REAL variables of any KIND can no longer be used as DO loop control variables and expressions. You can replace such DO loops with the appropriate DO WHILE loop that explicitly initializes, increments, and tests the REAL variable. For example, replace:

```
DO X = 0.1, 0.5, 0.01
   ...
END DO
```

  with:

```
X = 0.1
DO WHILE (X .LE. 0.5)
   ...
   X = X + 0.01
END DO
```

- Vertical format control

  Formatted output to certain printing output units used to result in the first character of each record being interpreted as controlling vertical spacing on the unit. There is no standard way to detect whether output to such a unit should result in such vertical format control and no way to specify that it should be applied. The effect can be achieved by post-processing a formatted file after it is created to interpret the first character as some form of control character. This is left to the user.

Intel Fortran flags these features if you specify compiler option stand.

See Also

Obsolescent Language Features in the Fortran Standard

`stand` compiler option

Obsolescent Language Features in the Fortran Standard

Some language features, considered redundant in older versions of the Fortran Standard, are identified as obsolescent in the current Fortran Standard.

Intel® Fortran flags these features if you specify compiler option stand.

Other methods are suggested to achieve the functionality of the following obsolescent features:

- Alternate returns (labels in an argument list)

To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program use a CASE construct to test the value and perform operations.

- Assumed-length character functions

  To replace this functionality, it is recommended that you use one of the following:

  - An automatic character-length function, where the length of the function result is declared in a specification expression
  - A subroutine whose arguments correspond to the function result and the function arguments

  Dummy arguments of a function can still have assumed character length; this feature is not obsolescent.
- BLOCK DATA subprograms

  BLOCK DATA was used to initialize COMMON block variables. This can be achieved with initialization of MODULE data when it is declared. MODULE data is the preferred method of sharing data between compilation units, and for replacing COMMON blocks.
- CHARACTER*(*) form of CHARACTER declaration

  To replace this functionality, it is recommended that you use the Fortran 90 forms of specifying a length selector in CHARACTER declarations (see Declaration Statements for Character Types).
- COMMON blocks

  To replace this functionality, it is recommended data specified in COMMON be declared in a MODULE which can be made available through USE association where the data is needed.
- Computed GO TO statement

  To replace this functionality, it is recommended that you use a CASE construct.
- DATA statements among executable statements

  This functionality has been included since FORTRAN 66, but is considered to be a potential source of errors.
- ENTRY statement

  To replace this functionality, it is recommended that you use multiple module procedures that can access shared data in the module.
- EQUIVALENCE

  The use of storage association thru EQUIVALENCE statements is not recommended.
- Fixed source form

  Newer methods of entering data have made this source form obsolescent and error-prone.

  The recommended method for coding is to use free source form.
- FORALL statement and construct

  These were added to the language with the expectation they would result in very efficient and possibly parallel code. The complexity and many restrictions prevented compilers from taking advantage of them.

  The DO CONCURRENT construct makes FORALL redundant. Data manipulations which can be done with FORALL can be done more effectively with pointers using rank remapping. Both the FORALL statement form and the construct became obsolescent in Fortran 2018.
- Labeled DO loops

  To replace this functionality, it is recommended that you use an END DO statements to terminate loops, and CYCLE statements to branch to the end of the loop to start the next iteration of the loop (or exit the loop, if the last iteration of the loop takes the branch).
- Statement functions

  To replace this functionality, it is recommended that you use an internal function.
- Specific names of intrinsic functions that also have generic names

  To replace this functionality, it is recommended that you use the generic names.

Additional Language Features

To facilitate compatibility with older versions of Fortran, Intel® Fortran provides additional language features. Some are discussed in this section.

Others language features that facilitate compatibility with older versions of Fortran are the following:

- The DEFINE FILE statement
- The ENCODE and DECODE statements
- The FIND statement
- The INTERFACE TO statement
- The integer POINTER statement
- The VIRTUAL statement

These language features are particularly useful in porting older Fortran programs to Standard Fortran. However, you should avoid using them in new programs on these systems, and in new programs for which portability to other Standard Fortran implementations is important.

FORTRAN 66 Interpretation of the EXTERNAL Statement

If you specify compiler option f66, the EXTERNAL statement is interpreted in the way that was specified by the FORTRAN 66 (FORTRAN IV) standard. This interpretation became incompatible with FORTRAN 77 and later revisions of the Fortran standard.

The FORTRAN 66 interpretation of the EXTERNAL statement combines the functionalities of the INTRINSIC statement and the EXTERNAL statement.

This lets you use subprograms as arguments to other subprograms. The subprograms to be used as arguments can be either user-supplied procedures or Fortran intrinsic procedures.

The FORTRAN 66 EXTERNAL statement takes the following form:

EXTERNAL [*]*v* [, [*]*v*] ...

*	Specifies that a user-supplied external procedure is to be used instead of a Fortran intrinsic procedure having the same name. This modifier is not standard FORTRAN 66, but was an extension in some FORTRAN 66 compilers, and provides the FORTRAN 77 meaning of EXTERNAL where required.
v	Is the name of a subprogram or the name of a dummy argument associated with the name of a subprogram.

Description

The FORTRAN 66 EXTERNAL statement declares that each name in its list is an external procedure name. Such a name can then be used as an actual argument to a subprogram, which then can use the corresponding dummy argument in a function reference or CALL statement.

However, when used as an argument, a complete function reference represents a value, not a subprogram name; for example, SQRT(B) in CALL SUBR(A, SQRT(B), C). Therefore, it does not need to be defined in an EXTERNAL statement. Note that the incomplete reference SQRT *would* need to be defined in an EXTERNAL statement.

Examples

The following example, when compiled with compiler option f66, shows the FORTRAN 66 EXTERNAL statement:

```
Main Program                        Subprograms
EXTERNAL SIN, COS, *TAN, SINDEG     SUBROUTINE TRIG(X,F,Y)
   .                                Y = F(X)
   .                                RETURN
   .                                END
CALL TRIG(ANGLE, SIN, SINE)
   .
   .                                FUNCTION TAN(X)
   .                                TAN = SIN(X)/COS(X)
CALL TRIG(ANGLE, COS, COSINE)       RETURN
```

```
   .                                 END
   .
   .
CALL TRIG(ANGLE, TAN, TANGNT)        FUNCTION SINDEG(X)/
   .                                 SINDEG = SIN(X*3.1459/180)
   .                                 RETURN
   .                                 END
CALL TRIG(ANGLED, SINDEG, SINE)
```

The CALL statements pass the name of a function to the subroutine TRIG. The function reference F(X) subsequently invokes the function in the second statement of TRIG. Depending on which CALL statement invoked TRIG, the second statement is equivalent to one of the following:

```
Y = SIN(X)
Y = COS(X)
Y = TAN(X)
Y = SINDEG(X)
```

The functions SIN and COS are examples of trigonometric functions supplied in the Fortran intrinsic procedure library. The function TAN is also supplied in the library, but the asterisk (*) in the EXTERNAL statement specifies that the user-supplied function be used, instead of the intrinsic function. The function SINDEG is also a user-supplied function. Because no library function has the same name, no asterisk is required.

f66 compiler option

Alternative Syntax for the PARAMETER Statement

The PARAMETER statement discussed here is similar to the one discussed in PARAMETER; they both assign a name to a constant. However, this PARAMETER statement differs from the other one in the following ways:

- Its list is not bounded with parentheses.
- The form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

This PARAMETER statement takes the following form:

PARAMETER *c* = *expr* [, *c* = *expr*] ...

c	Is the name of the constant.
expr	Is a constant expression. It can be of any data type.

Description

Each name *c* becomes a constant and is defined as the value of expression *expr*. Once a name is defined as a constant, it can appear in any position in which a constant is allowed. The effect is the same as if the constant were written there instead of the name.

The name of a constant cannot appear as part of another constant, except as the real or imaginary part of a complex constant. For example:

```
  PARAMETER I=3
  PARAMETER M=I.25            ! Not allowed
  PARAMETER N=(1.703, I)      ! Allowed
```

The name used in the PARAMETER statement identifies only the name's corresponding constant in that program unit. Such a name can be defined only once in PARAMETER statements within the same program unit.

The name of a constant assumes the data type of its corresponding constant expression. The data type of a parameter constant cannot be specified in a type declaration statement. Nor does the initial letter of the constant's name implicitly affect its data type.

Examples

The following are valid examples of this form of the PARAMETER statement:

```
PARAMETER PI=3.1415927, DPI=3.141592653589793238D0
PARAMETER PIOV2=PI/2, DPIOV2=DPI/2
PARAMETER FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS'
```

PARAMETER for details on compile-time constant expressions

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

In Intel® Fortran, you can use an alternative syntax for binary, octal, and hexadecimal constants. The following table shows the alternative syntax and equivalents:

Constant	Alternative Syntax	Equivalent
Binary	'0..1'B	B'0..1'
Octal	'0..7'O	O'0..7'
Hexadecimal	'0..F'X	Z'0..F'
	X'0..F'	

You can use a quotation mark (") in place of an apostrophe in all the above syntax forms.

For information on the # syntax for integers not in base 10, see Integer Constants.

See Also

Binary constants
Octal constants
Hexadecimal constants

Alternative Syntax for a Record Specifier

In Intel® Fortran, you can specify the following form for a record specifier in an I/O control list:

'*r*

r — Is a numeric expression with a value that represents the position of the record to be accessed using direct access I/O.

The value must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file. If necessary, a record number is converted to integer data type before being used.

If this nonkeyword form is used in an I/O control list, it must immediately follow the nonkeyword form of the io-unit specifier.

Alternative Syntax for the DELETE Statement

In Intel® Fortran, you can specify the following form of the DELETE statement when deleting records from a relative file:

DELETE (*io-unit* '*r* [, ERR=*label*] [, IOSTAT=*i-var*])

io-unit — Is the number of the logical unit containing the record to be deleted.

r	Is the positional number of the record to be deleted.
label	Is the label of an executable statement that receives control if an error condition occurs.
i-var	Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

This form deletes the direct access record specified by *r*.

DELETE statement

Alternative Form for Namelist External Records

In Intel® Fortran, you can use the following form for an external record:

$*group-nameobject* = *value* [*object* = *value*] ...$[END]

group-name	Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit.
object	Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks, but it can be preceded or followed by blanks.
value	Is a null value, a constant (or list of constants), a repetition of constants in the form r*c, or a repetition of null values in the form r*.

If more than one *object=value* or more than one value is specified, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks.

Record Structures

The record structure was defined in earlier versions of Intel® Fortran as a language extension. It is still supported, although its functionality has been replaced by Standard Fortran derived data types.

Record structures in existing code can be easily converted to Standard Fortran derived type structures for portability, but can also be left in their old form. In most cases, an Intel Fortran record and a Standard Fortran derived type can be used interchangeably.

Intel Fortran record structures are similar to Standard Fortran derived types.

A *record structure* is an aggregate entity containing one or more elements. (Record elements are also called fields or components.) You can use records when you need to declare and operate on multi-field data structures in your programs.

Creating a record is a two-step process:

1. You must define the form of the record with a multistatement *structure declaration*.
2. You must use a RECORD statement to declare the record as an entity with a name. (More than one RECORD statement can refer to a given structure.)

Examples

Intel Fortran record structures, using only intrinsic types, easily convert to Standard Fortran derived types. The conversion can be as simple as replacing the keyword STRUCTURE with TYPE and removing slash (/) marks. The following shows an example conversion:

Record Structure	Standard Fortran Derived-Type

`STRUCTURE /employee_name/`
`  CHARACTER*25  last_name`
`  CHARACTER*15  first_name`
`END STRUCTURE`
`STRUCTURE /employee_addr/`
`  CHARACTER*20  street_name`
`  INTEGER(2)  street_number`
`  INTEGER(2)  apt_number`
`  CHARACTER*20  city`
`  CHARACTER*2  state`
`  INTEGER(4)  zip`
`END STRUCTURE`
	`TYPE employee_name`
	`  CHARACTER*25  last_name`
	`  CHARACTER*15  first_name`
	`END TYPE`
	`TYPE employee_addr`
	`  CHARACTER*20  street_name`
	`  INTEGER(2)  street_number`
	`  INTEGER(2)  apt_number`
	`  CHARACTER*20  city`
	`  CHARACTER*2  state`
	`  INTEGER(4)  zip`
	`END TYPE`

The record structures can be used as subordinate record variables within another record, such as the `employee_data` record. The equivalent Standard Fortran derived type would use the derived-type objects as components in a similar manner, as shown below:

Record Structure	Standard Fortran Derived-Type

`STRUCTURE /employee_data/`
`  RECORD  /employee_name/ name`
`  RECORD  /employee_addr/ addr`
`  INTEGER(4) telephone`
`  INTEGER(2) date_of_birth`
`  INTEGER(2) date_of_hire`
`  INTEGER(2) social_security(3)`
`  LOGICAL(2) married`
`  INTEGER(2) dependents`
`END STRUCTURE`
	`TYPE employee_data`
	`  TYPE (employee_name) name`
	`  TYPE (employee_addr) addr`
	`  INTEGER(4) telephone`
	`  INTEGER(2) date_of_birth`
	`  INTEGER(2) date_of_hire`
	`  INTEGER(2) social_security(3)`
	`  LOGICAL(2) married`
	`  INTEGER(2) dependents`
	`END TYPE`

RECORD Statement

Structure Declarations

A *structure declaration* defines the field names, types of data within fields, and order and alignment of fields within a record. Fields and structures can be initialized, but records cannot be initialized. For more information, see STRUCTURE.

See Also

Union Declarations

Type Declarations within Record Structures

The syntax of a type declaration within a record structure is identical to that of a normal Fortran type statement.

The following rules and behavior apply to type declarations in record structures:

- %FILL can be specified in place of a field name to leave space in a record for purposes such as alignment. This creates an unnamed field.

  %FILL can have an array specification; for example:

```
INTEGER %FILL (2,2)
```

  Unnamed fields cannot be initialized. For example, the following statement is invalid and generates an error message:

```
INTEGER %FILL /1980/
```

- Initial values can be supplied in field declaration statements. Unnamed fields cannot be initialized; they are always undefined.
- Field names must always be given explicit data types. The IMPLICIT statement does not affect field declarations.
- Any required array dimensions must be specified in the field declaration statements. DIMENSION statements cannot be used to define field names.
- Adjustable or assumed sized arrays and assumed-length CHARACTER declarations are not allowed in field declarations.

Substructure Declarations

A field within a structure can itself be a structured item composed of other fields, other structures, or both. You can declare a substructure in two ways:

- By nesting structure declarations within other structure or union declarations (with the limitation that you cannot refer to a structure inside itself at any level of nesting).

  One or more field names must be defined in the STRUCTURE statement for the substructure, because all fields in a structure must be named. In this case, the substructure is being used as a field within a structure or union.

  Field names within the same declaration nesting level must be unique, but an inner structure declaration can include field names used in an outer structure declaration without conflict.
- By using a RECORD statement that specifies another previously defined record structure, thereby including it in the structure being declared.

See the example in STRUCTURE for a sample structure declaration containing both a nested structure declaration (TIME) and an included structure (DATE).

References to Record Fields

References to record fields must correspond to the kind of field being referenced. Aggregate field references refer to composite structures (and substructures). Scalar field references refer to singular data items, such as variables.

An operation on a record can involve one or more fields.

Record field references take one of the following forms:

Aggregate Field Reference:

record-name [.*aggregate-field-name*] ...

Scalar Field Reference:

record-name [.*aggregate-field-name*] ... .*scalar-field-name*

record-name	Is the name used in a RECORD statement to identify a record.
aggregate-field-name	Is the name of a field that is a substructure (a record or a nested structure declaration) within the record structure identified by the record name.

scalar-field-name	Is the name of a data item (having a data type) defined within a structure declaration.

Description

Records and record fields cannot be used in DATA statements, but individual fields can be initialized in the STRUCTURE definition.

An automatic array cannot be a record field.

A scalar field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names followed by the name of a scalar field. A scalar field reference refers to a single data item (having a data type) and can be treated like a normal reference to a Fortran variable or array element.

You can use scalar field references in statement functions and in executable statements. However, they cannot be used in COMMON, SAVE, NAMELIST, or EQUIVALENCE statements, or as the control variable in an indexed DO-loop.

Type conversion rules for scalar field references are the same as those for variables and array elements.

An aggregate field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names.

You can only assign an aggregate field to another aggregate field (record = record) if the records have the same structure. Intel® Fortran supports no other operations (such as arithmetic or comparison) on aggregate fields.

Intel Fortran requires qualification on all levels. While some languages allow omission of aggregate field names when there is no ambiguity as to which field is intended, Intel Fortran requires all aggregate field names to be included in references.

You can use aggregate field references in unformatted I/O statements; one I/O record is written no matter how many aggregate and array name references appear in the I/O list. You cannot use aggregate field references in formatted, namelist, and list-directed I/O statements.

You can use aggregate field references as actual arguments and record dummy arguments. The declaration of the dummy record in the subprogram must match the form of the aggregate field reference passed by the calling program unit; each structure must have the same number and types of fields in the same order. The order of map fields within a union declaration is irrelevant.

Records are passed by reference. Aggregate field references are treated like normal variables. You can use adjustable arrays in RECORD statements that are used as dummy arguments.

Examples

The following examples show record and field references. Consider the following structure declarations:

Structure DATE:

```
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
STRUCTURE
```

Structure APPOINTMENT:

```
STRUCTURE /APPOINTMENT/
  RECORD /DATE/      APP_DATE
  STRUCTURE /TIME/   APP_TIME(2)
    INTEGER*1        HOUR, MINUTE
  END STRUCTURE
```

```
  CHARACTER*20       APP_MEMO(4)
  LOGICAL*1          APP_FLAG
END STRUCTURE
```

The following RECORD statement creates a variable named NEXT_APP and a 10-element array named APP_LIST. Both the variable and each element of the array take the form of the structure APPOINTMENT.

```
RECORD /APPOINTMENT/    NEXT_APP,APP_LIST(10)
```

Each of the following examples of record and field references are derived from the previous structure declarations and RECORD statement:

Aggregate Field References

- The record NEXT_APP:

```
NEXT_APP
```

- The field APP_DATE, a 4-byte array field in the record array APP_LIST(3):

```
APP_LIST(3).APP_DATE
```

Scalar Field References

- The field APP_FLAG, a LOGICAL field of the record NEXT_APP:

```
NEXT_APP.APP_FLAG
```

- The first character of APP_MEMO(1), a CHARACTER*20 field of the record NEXT_APP:

```
NEXT_APP.APP_MEMO(1)(1:1)
```

NOTE
Because periods are used in record references to separate fields, you should avoid using relational operators (.EQ., .XOR.), logical constants (.TRUE., .FALSE.), and logical expressions (.AND., .NOT., .OR.) as field names in structure declarations. Dots can also be used instead of % to separate fields of a derived type.

Consider the following example:

```
module mod
   type T1_t
     integer :: i
   end type T1_t
  type T2_t
     type (T1_t) :: eq
     integer     :: i
  end type T2_t

  interface operator (.eq.)
     module procedure eq_func
  end interface operator (.eq.)
contains
  function eq_func(t2, i) result (rslt)
  type(T2_t), intent (in) :: t2
  integer,    intent (in) :: i
      rslt = t2%eq%i + i
  end function eq_func
end module mod

use mod
type(T2_t) :: t2
```

```
integer    :: i
  t2%eq%i = 0
  t2%i    = -10
  i       = -10
  print *, t2.eq.i, (t2).eq.i
end
```

In this case, the reference "t2.eq.i" prints 0. The reference "(t2).eq.i" will invoke eq_func and will print -10.

Aggregate Assignment

For aggregate assignment statements, the variable and expression must have the same structure as the aggregate they reference.

The aggregate assignment statement assigns the value of each field of the aggregate on the right of an equal sign to the corresponding field of the aggregate on the left. Both aggregates must be declared with the same structure.

Examples

The following example shows valid aggregate assignments:

```
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

RECORD /DATE/ TODAY, THIS_WEEK(7)
STRUCTURE /APPOINTMENT/
  ...
  RECORD /DATE/ APP_DATE
END STRUCTURE

RECORD /APPOINTMENT/ MEETING

DO I =  1,7
  CALL GET_DATE (TODAY)
  THIS_WEEK(I) =     TODAY
  THIS_WEEK(I).DAY = TODAY.DAY + 1
END DO
MEETING.APP_DATE =   TODAY
```

Additional Character Sets

This topic contains information about the additional character sets you can use in your Fortran programs.

ANSI Character Codes for Windows*

The ANSI character code chart lists the extended character set of most of the programs used by Windows operating systems. The codes of the ANSI (American National Standards Institute) character set from 32 through 126 are displayable characters from the ASCII character set. The ANSI characters displayed as solid blocks are undefined characters and may appear differently on output devices.

■ Indicates that this character isn't supported by Windows.

TT Indicates that this character is available only in TrueType fonts.

Key Codes for Windows*

Some keys, such as function keys, cursor keys, and ALT+KEY combinations, have no ASCII code. When a key is pressed, a microprocessor within the keyboard generates an "extended scan code" of two bytes.

The first (low-order) byte contains the ASCII code, if any. The second (high-order) byte has the scan code--a unique code generated by the keyboard when a key is either pressed or released. Because the extended scan code is more extensive than the standard ASCII code, programs can use it to identify keys which do not have an ASCII code.

Key Codes Chart 1 (Windows)

† Extended codes return 0 (NUL) or E0 (decimal 224) as the initial character. This is a signal that a second (extended) code is available in the keystroke buffer.
§§ These key combinations are only recognized on extended keyboards.
£ These keys are only available on extended keyboards. Most are in the Cursor/Control cluster. If the raw scan code is read from the keyboard port (60h), it appears as two bytes (E0h) followed by the normal scan code. However, when the keypad ENTER and / keys are read through the BIOS interrupt 16h, only E0h is seen since the interrupt only gives one-byte scan codes.
†† Under MS-DOS, SHIFT + PRTSC causes interrupt 5, which prints the screen unless an interrupt handler has been defined to replace the default interrupt 5 handler.

ASCII Character Set for Linux*

This topic describes the ASCII character set that is available on Linux* operating systems.

The ASCII character set contains characters with decimal values 0 through 127. The first half of each of the numbered columns identifies the character as you would enter it on a terminal or as you would see it on a printer. Except for SP and HT, the characters with names are nonprintable. In the figure, the characters with names are defined as follows:

NUL	Null	DC1	Device Control 1 (XON)
SOH	Start of Heading	DC2	Device Control 2

STX	Start of Text	DC3	Device Control 1 (XOFF)
ETX	End of Text	DC4	Device Control 4
EOT	End of Transmission	NAK	Negative Acknowledge
ENQ	Enquiry	SYN	Synchronous Idle
ACK	Acknowledge	ETB	End of Transmission Block
BEL	Bell	CAN	Cancel
BS	Backspace	EM	End of Medium
HT	Horizontal Tab	SUB	Substitute
LF	Line Feed	ESC	Escape
VT	Vertical Tab	FS	File Separator
FF	Form Feed	GS	Group Separator
CR	Carriage Return	RS	Record Separator
SO	Shift Out	US	Unit Separator
SI	Shift In	SP	Space
DLE	Data Link Escape	DEL	Delete

The remaining half of each column identifies the character by the binary value of the byte; the value is stated in three radixes—octal, decimal, and hexadecimal. For example, the uppercase letter A has, under ASCII conventions, a storage value of hexadecimal 41 (a bit configuration of 01000001), equivalent to 101 in octal notation and 65 in decimal notation.

The following is the ASCII Character Set for Linux.

Row	Bits b8 b7 b6 b5 b4 b3 b2 b1	0		1		2		3		4		5		6		7

Data Representation Models

Several of the numeric intrinsic functions are defined by a model set for integers (for each intrinsic kind used) and reals (for each real kind used). The bit functions are defined by a model set for bits (binary digits).

The following intrinsic functions provide information on the data representation models:

Intrinsic function	Model	Value returned
BIT_SIZE	Bit	The number of bits (s) in the bit model
DIGITS	Integer or Real	The number of significant digits in the model for the argument
EPSILON	Real	The number that is almost negligible when compared to one
EXPONENT	Real	The value of the exponent part of a real argument
FRACTION	Real	The fractional part of a real argument
HUGE	Integer or Real	The largest number in the model for the argument
MAXEXPONENT	Real	The maximum exponent in the model for the argument
MINEXPONENT	Real	The minimum exponent in the model for the argument
NEAREST	Real	The nearest different machine-representable number in a given direction
PRECISION	Real	The decimal precision (real or complex) of the argument
RADIX	Integer or Real	The base of the model for the argument
RANGE	Integer or Real	The decimal exponent range of the model for the argument
RRSPACING	Real	The reciprocal of the relative spacing near the argument
SCALE	Real	The value of the exponent part (of the model for the argument) changed by a specified value
SET_EXPONENT	Real	The value of the exponent part (of the model for the argument) set to a specified value
SPACING	Real	The value of the absolute spacing of model numbers near the argument
TINY	Real	The smallest positive number in the model for the argument

For more information on the range of values for each data type (and kind), see Data and I/O in the *Compiler Reference*.

Model for Integer Data

In general, the model set for integers is defined as follows:

$$i = s \times \sum_{k=1}^{q} w_k \times r^{k-1}$$

The following values apply to this model set:

- *i* is the integer value.
- *s* is the sign (either +1 or -1).
- *q* is the number of digits (a positive integer).
- *r* is the radix (an integer greater than 1).
- w_k is a nonnegative number less than *r*.

The model for INTEGER(4) follows:

$$i = s \times \sum_{k=1}^{31} w_k \times 2^{k-1}$$

The following example shows the general integer model for *i* = -20 using a base (*r*) of 2:

$$i = (-1) \times (0 \times 2^0 + 0 \times 2^1 + 1 \times 2^2 + 0 \times 2^3 + 1 \times 2^4)$$

$$i = (-1) \times (4 + 16)$$

$$i = -1 \times 20$$

$$i = -20$$

Model for Real Data

The model set for reals, in general, is defined as one of the following:

$$x = 0$$

$$x = s \times b^e \times \sum_{k=1}^{p} f_k \times b^{-k}$$

The following values apply to this model set:

- *x* is the real value.
- *s* is the sign (either +1 or -1).
- *b* is the base (real radix; an integer greater than 1; *b* = 2 in Intel® Fortran).
- *p* is the number of mantissa digits (an integer greater than 1). The number of digits differs depending on the real format, as follows:

REAL(4)	IEEE binary32	24
REAL(8)	IEEE binary64	53
REAL(16)	IEEE binary128	113

- *e* is an integer in the range e_{min} to e_{max} inclusive. This range differs depending on the real format, as follows:

		e_{min}	e_{max}
REAL(4)	IEEE binary32	-125	128
REAL(8)	IEEE binary64	-1021	1024
REAL(16)	IEEE binary128	-16381	16384

- f_k is a nonnegative number less than *b* (f_1 is also nonzero).

For x = 0, its exponent *e* and digits f_k are defined to be zero.

The model set for single-precision real (REAL(4)) is defined as one of the following:

$$x = 0$$

$$x = s \times 2^{e} \times \left[1/2 + \sum_{k=2}^{24} f_k \times 2^{-k}\right], -125 \le e \le 128$$

The following example shows the general real model for x = 20.0 using a base (b) of 2:

$$x = 1 \times 2^{5} \times (1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3})$$

$$x = 1 \times 32 \times (.5 + .125)$$

$$x = 32 \times (.625)$$

$$x = 20.0$$

Model for Bit Data

The model set for bits (binary digits) interprets a binary digit w located at position k of a nonnegative integer scalar object based on a model nonnegative integer defined by the following:

$$j = \sum_{k=0}^{s-1} w_k \times 2^{k}$$

The following values apply to this model set:

- j is the integer value.
- s is the number of bits (the length of a sequence of bits).
- w_k is a bit value of 0 or 1. This defines a sequence of bits $w_{s-1}...w_0$, with w_{s-1} the leftmost bit and w_0 the rightmost bit. The positions of bits in the sequence are numbered from right to left, with the position of the rightmost bit being zero.

The interpretation of a negative integer as a sequence of bits is processor dependent.

The inquiry function BIT_SIZE provides the value of the parameter s of the model.

The following example shows the bit model for j = 1001 (integer 9) using a bit number (s) of 4:

$$\begin{array}{cccc} 1 & 0 & 0 & 1 \\ \downarrow & \downarrow & \downarrow & \downarrow \\ w_3 & w_2 & w_1 & w_0 \end{array}$$

$$j = (w_0 \times 2^{0}) + (w_1 \times 2^{1}) + (w_2 \times 2^{2}) + (w_3 \times 2^{3})$$

$$j = 1 + 0 + 0 + 8$$

$$j = 9$$

See Also

BIT_SIZE

Bit Sequence Comparisons

When bit sequences of unequal length are compared, the shorter sequence is padded with zero bits on the left, so that it is the same length as the longer sequence.

Bit sequences are compared from left to right, one bit at a time, until unequal bits are found, or until all bits have been compared and found to be equal.

If unequal bits are found, the sequence with zero in the unequal position is considered to be less than the sequence with one in the unequal position. Otherwise the sequences are considered to be equal.

Library Modules and Runtime Library Routines

Intel® Fortran provides a library of modules that contain routines you can use in your programs:

Module Name	Description
IFAUTO	Interfaces to Automation library routines
IFCOM	Interfaces to COM library routines
IFCOMMONALLOC	Interface to a user-defined routine to dynamically allocate commons
IFCORE	Interfaces to miscellaneous runtime library routines
IFESTABLISH	Interface to a routine to handle Runtime Library (RTL) errors
IFLOGM	Interfaces to routines from the dialog library
IFMT	Defines derived types for Thread/Process/Synchronization Windows APIs
IFNLS	Interfaces to National Language Support routines
IFPORT	Interfaces to portability routines
IFPOSIX	Interfaces to Posix-compliant routines
IFQWIN	Interfaces to QuickWin and Graphics library routines
IFWINTY	Defines Fortran parameter constants and derived data types for use with Windows APIs
KERNEL32	Interfaces to the Windows APIs provided by kernel32.dll

NOTE
The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

Runtime Library Routines

Intel® Fortran provides library modules containing the following routines. Note that the links in this list go to the relevant language summary table:

- Routines that help you write programs for graphics, QuickWin, and other applications (in modules IFQWIN, IFLOGM, and IFCORE):
  - QuickWin routines for Windows
  - Graphics routines for Windows
  - Dialog routines for Windows
  - Miscellaneous runtime routines
- Routines systems that help you write programs using Component Object Model (COM) and Automation servers (in modules IFCOM and IFAUTO):
  - COM routines for Windows
  - AUTO routines for Windows
- Portability routines that help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows* systems (in module IFPORT).

- National Language Support routines that help you write foreign language programs for international markets (in module IFNLS). These routines are only available on Windows* systems.
- POSIX routines that help you write Fortran programs that comply with the POSIX* Standard (in module IFPOSIX).
- ESTABLISHQQ lets you specify a routine to handle Runtime Library (RTL) errors (in module IFESTABLISH).
- FOR_SET_FTN_ALLOC lets you specify a user-defined routine to dynamically allocate commons. The caller of FOR_SET_FTN_ALLOC must include module IFCOMMONALLOC.

When you include the statement USE *module-name* in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement.

NOTE
The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

USE

NLS and MCBS Routines on Windows

The NLS and MCBS routines are only available on Windows* systems. These library routines for handling extended and multibyte character sets are divided into three categories:

- Locale Setting and Inquiry routines to set locales (local code sets) and inquire about their current settings

  At program startup, the current language and country setting is retrieved from the operating system. The user can change this setting through the Control Panel Regional Settings icon. The current codepage is also retrieved from the system.

  There is a system default console codepage and a system default Windows codepage. Console programs retrieve the system console codepage, while Windows programs (including QuickWin applications) retrieve the system Windows codepage.

  The NLS Library provides routines to determine the current locale (local code set), to return parameters of the current locale, to provide a list of all the system supported locales, and to set the locale to another language, country and/or codepage. Note that the locales and codepages set with these routines affect only the program or console that calls the routine. They do not change the system defaults or affect other programs or consoles.
- NLS Formatting routines to format dates, currency, and numbers

  You can set time, date, currency and number formats from the Control Panel, by clicking on the Regional Settings icon. The NLS Library also provides formatting routines for the current locale. These routines return strings in the current codepage, set by default at program start or by NLSSetLocale.

  All the formatting routines return the number of bytes in the formatted string (not the number of characters, which can vary if multibyte characters are included). If the output string is longer than the formatted string, the output string is blank padded. If the output string is shorter than the formatted string, an error occurs, NLS$ErrorInsufficientBuffer is returned, and nothing is written to the output string.
- Multibyte Character Set (MBCS) routines for using multi-byte characters

  Examples of multibyte character sets are Japanese, Korean, and Chinese.

  - The MBCS inquiry routines provide information on the maximum length of multibyte characters, the length, number and position of multibyte characters in strings, and whether a multibyte character is a leading or trailing byte. The NLS library provides a parameter, MBLenMax, defined in the NLS module to be the longest length (in bytes) of any character, in any codepage. This parameter can be useful in comparisons and tests. To determine the maximum character length of the current codepage, use the MBCurMax function.

- There are four MBCS conversion routines. Two convert Japan Industry Standard (JIS) characters to Microsoft Kanji characters or vice versa. Two convert between a codepage multibyte character string and a Unicode string.
- There are several MBCS Fortran equivalent routines. They are the exact equivalents of Fortran intrinsic routines except that the MBCS equivalents allow character strings to contain multibyte characters.

Examples

The following example uses Locale Setting and Inquiry routines:

```
    USE IFNLS
    INTEGER(4) strlen, status
    CHARACTER(40) str
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
    print *, str    ! prints Monday
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
    print *, str    ! prints Tuesday
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
    print *, str    ! prints Wednesday
! Change locale to Spanish, Mexico
    status = NLSSetLocale("Spanish", "Mexico")
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
    print *, str    ! prints lunes
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
    print *, str    ! prints martes
    strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
    print *, str    ! prints miércoles
    END
```

The following example uses NLS Formatting routines:

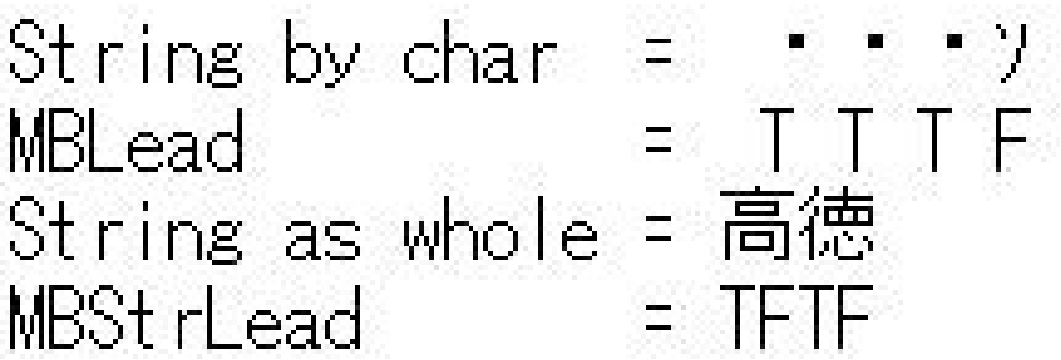
```
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str
strlen = NLSFormatTime(str)
print *, str             ! prints               11:42:24 AM
strlen = NLSFormatDate(str, flags= NLS$LongDate)
print *, str             ! prints        Friday, July 14, 2000
status = NLSSetLocale ("Spanish", "Mexico")
strlen = NLSFormatTime(str)
print *, str             ! prints               11:42:24
print *, str             ! prints viernes 14 de julio de 2000
```

The following example uses Multibyte Character Set (MBCS) inquiry routines:

```
  USE IFNLS
  CHARACTER(4) str
  INTEGER status
  status = NLSSetLocale ("Japan")
  str = " ･, " ¿"
  PRINT '(1X,''String by char = '',\)'
  DO i = 1, len(str)
     PRINT '(A2,\)',str(i:i)
  END DO
  PRINT '(/,1X,''MBLead = '',\)'
  DO i = 1, len(str)
     PRINT '(L2,\)',mblead(str(i:i))
  END DO
```

```
  PRINT '(/,1X,''String as whole = '',A,\)',str
  PRINT '(/,1X,''MBStrLead = '',\)'
  DO i = 1, len(str)
     PRINT '(L1,\)',MBStrLead(str,i)
  END DO
  END
```

This code produces the following output for *str* = · , " ¿



The following example uses Multibyte Character Set (MBCS) Fortran equivalent routines:

```
  USE IFNLS
  INTEGER(4) i, len(7), infotype(7)
  CHARACTER(10) str(7)
  LOGICAL(4) log4
  data infotype / NLS$LI_SDAYNAME1, NLS$LI_SDAYNAME2, &
 & NLS$LI_SDAYNAME3, NLS$LI_SDAYNAME4, &
 & NLS$LI_SDAYNAME5, NLS$LI_SDAYNAME6, &
 & NLS$LI_SDAYNAME7 /
  WRITE(*,*) 'NLSGetLocaleInfo'
  WRITE(*,*) '----------------'
  WRITE(*,*) ' '
  WRITE(*,*) 'Getting the names of the days of the week...'
  DO i = 1, 7
     len(i) = NLSGetLocaleInfo(infotype(i), str(i))
     WRITE(*, 11) 'len/str/hex = ', len(i), str(i), str(i)
  END DO
11 FORMAT (1X, A, I2, 2X, A10, 2X, '[', Z20, ']')
  WRITE(*,*) ' '
  WRITE(*,*) 'Lexically comparing the names of the days...'
  DO i = 1, 6
     log4 = MBLGE(str(i), str(i+1), NLS$IgnoreCase)
     WRITE(*, 12) 'Is day ', i, ' GT day ', i+1, '? Answer = ', log4
  END DO
12 FORMAT (1X, A, I1, A, I1, A, L1)
  WRITE(*,*) ' '
  WRITE(*,*) 'Done.'
  END
```

This code produces the following output when the locale is Japan:

```
NLSGetLocaleInfo
----------------

Getting the names of the days of the week...
len/str/hex =  6  月曜日      [8C8E976A93FA20202020]
len/str/hex =  6  火曜日      [89CE976A93FA20202020]
len/str/hex =  6  水曜日      [9085976A93FA20202020]
len/str/hex =  6  木曜日      [96D8976A93FA20202020]
len/str/hex =  6  金曜日      [8BE0976A93FA20202020]
len/str/hex =  6  土曜日      [9379976A93FA20202020]
len/str/hex =  6  日曜日      [93FA976A93FA20202020]

Lexically comparing the names of the days...
Is day 1 GT day 2?  Answer = T
Is day 2 GT day 3?  Answer = F
Is day 3 GT day 4?  Answer = F
Is day 4 GT day 5?  Answer = T
Is day 5 GT day 6?  Answer = F
Is day 6 GT day 7?  Answer = F

Done.
```

Standard Fortran Routines That Handle MBCS Characters
USE

Standard Fortran Routines that Handle MBCS Characters on Windows

This section describes Fortran routines that work as usual even if MBCS characters are included in strings.

Because a space can never be a lead or tail byte, many routines that deal with spaces work as expected on strings containing MBCS characters. Such functions include:

- ADJUSTL (*string*)
- ADJUSTR (*string*)
- TRIM (*string*)

Some routines work with the computer collating sequence to return a character in a certain position in the sequence or the position in the sequence of a certain character. These functions are not dependent on a particular collating sequence. (You should note, however, that elsewhere in this manual the ASCII collating sequence is mentioned in reference to these functions.) Such functions use *position* and *c* values between 0 and 255 (inclusive) and include:

- ACHAR (*position*)
- CHAR (*position*[,*kind*])
- IACHAR (*c*)
- ICHAR (*c*)

Because Fortran uses character lengths instead of NULLs to indicate the length of a string, some functions work solely from the length of the string, and not with the contents of the string. This function works as usual on strings containing MBCS characters, and include:

REPEAT (*string*, *ncopies*)

Portability Routines

This section summarizes portability routines.

Information Retrieval Routines

Information retrieval routines return information about system commands, command-line arguments, environment variables, and process or user information.

Group, user, and process ID are INTEGER(4) variables. Login name and host name are character variables. The functions GETGID and GETUID are provided for portability, but always return 1.

Process Control Routines

Process control routines control the operation of a process or subprocess. You can wait for a subprocess to complete with either SLEEP or ALARM, monitor its progress and send signals via KILL, and stop its execution with ABORT.

In spite of its name, KILL does not necessarily stop execution of a program. Rather, the routine signaled could include a handler routine that examines the signal and takes appropriate action depending on the code passed.

Note that when you use SYSTEM, commands are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The portability library does not include the FORK routine. On Linux* systems, FORK creates a duplicate image of the parent process. Child and parent processes each have their own copies of resources, and become independent from one another.

On Windows* systems, you can create a child process (called a thread), but both parent and child processes share the same address space and share system resources. If you need to create another process, use the CreateProcessWindows API routine.

Numeric Values and Conversion Routines

Numeric values and conversion routines are available for calculating Bessel functions, data type conversion, and generating random numbers. Some of these functions have equivalents in Standard Fortran, in which case the standard Fortran routines should be used.

Data object conversion can be accomplished by using the INT intrinsic function instead of LONG or SHORT. The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED perform the same functions as some random number functions that are shown in table Numeric Values and Conversion, which appears in Portability Library Routines.

Other bit manipulation functions such as AND, XOR, OR, LSHIFT, and RSHIFT are intrinsic functions. You do not need the IFPORT module to access them. Standard Fortran includes many bit operation routines, which are listed in the Bit Operation and Representation Routines table.

Input and Output Routines

The portability library contains routines that change file properties, read and write characters and buffers, and change the offset position in a file. These input and output routines can be used with standard Fortran input or output statements such as READ or WRITE on the same files, provided that you take into account the following:

- When used with direct files, after an FSEEK, GETC, or PUTC operation, the record number is the number of the next whole record. Any subsequent normal Fortran I/O to that unit occurs at the next whole record. For example, if you seek to absolute location 1 of a file whose record length is 10, the NEXTREC returned by an INQUIRE would be 2. If you seek to absolute location 10, NEXTREC would still return 2.
- On units with CARRIAGECONTROL='FORTRAN' (the default), PUTC and FPUTC characters are treated as carriage control characters if they appear in column 1.
- On sequentially formatted units, the C string "\n"c, which represents the carriage return/line feed escape sequence, is written as CHAR(13) (carriage return) and CHAR(10) (line feed), instead of just line feed, or CHAR(10). On input, the sequence 13 followed by 10 is returned as just 10. (The length of character string "\n"c is 1 character, whose ASCII value, indicated by ICHAR('\n'c), is 10.)
- Reading and writing is in a raw form for direct files. Separators between records can be read and overwritten. Therefore, be careful if you continue using the file as a direct file.

I/O errors arising from the use of these routines result in an Intel® Fortran runtime error.

Some portability file I/O routines have equivalents in Standard Fortran. For example, you could use the ACCESS function to check a file specified by name for accessibility according to mode. It tests a file for read, write, or execute permission, as well as checking to see if the file exists. It works on the file attributes as they exist on disk, not as a program's OPEN statement specifies them.

Instead of ACCESS, you can use the INQUIRE statement with the ACTION specifier to check for similar information. (The ACCESS function always returns 0 for read permission on FAT files, meaning that all files have read permission.)

Date and Time Routines

Various date and time routines are available to determine system time, or convert it to local time, Greenwich Mean Time, arrays of date and time elements, or an ASCII character string.

DATE and TIME are available as either a function or subroutine. Because of the name duplication, if your programs do not include the USE IFPORT statement, each separately compiled program unit can use only one of these versions. For example, if a program calls the subroutine TIME once, it cannot also use TIME as a function.

Standard Fortran includes date and time intrinsic subroutines. For more information, see DATE_AND_TIME.

Error Handling Routines

Error handling routines detect and report errors.

IERRNO error codes are analogous to *errno* on Linux* systems. The IFPORT module provides parameter definitions for many of UNIX's *errno* names, found typically in `errno.h` on UNIX systems.

IERRNO is updated only when an error occurs. For example, if a call to the GETC function results in an error, but two subsequent calls to PUTC succeed, a call to IERRNO returns the error for the GETC call. Examine IERRNO immediately after returning from one of the portability library routines. Other Standard Fortran routines might also change the value to an undefined value.

If your application uses multithreading, remember that IERRNO is set on a per-thread basis.

System, Drive, or Directory Control and Inquiry Routines

You can retrieve information about devices, directories, and files with the functions listed below. File names can be long file names or UNC file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications.

Standard Fortran provides the INQUIRE statement, which returns detailed file information either by file name or unit number. Use INQUIRE as an equivalent to FSTAT, LSTAT, or STAT. LSTAT and STAT return the same information; STAT is the preferred function.

Serial Port Routines on Windows

The serial port I/O (SPORT_*xxx*) routines help you perform basic input and output to serial ports.

Additional Routines

You can also use portability routines for program call and control, keyboards and speakers, file management, arrays, floating-point inquiry and control, IEEE* functionality, and other miscellaneous uses.

NOTE
On Windows* systems, all portability routines that take path names also accept long file names or UNC (Universal Naming Convention) file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications as well as MBCS (multiple-byte character set) characters.

Portability Routines
Overview of Serial Port I/O Routines

Serial Port I/O Routines on Windows

The serial port I/O (SPORT_*xxx*) routines help you perform basic input and output to serial ports. These routines are available only on Windows* systems.

The programming model is much the same as a normal file except the user does a connect (SPORT_CONNECT, SPORT_CONNECT_EX) and release (SPORT_RELEASE) to the port instead of an open and close of a file.

Two types of read and write operations (as determined in a mode on the connect call) are provided:

- Read and write arbitrary data from/to the port using SPORT_READ_DATA and SPORT_WRITE_DATA.
- Read and writes line-terminated data using SPORT_READ_LINE and SPORT_WRITE_LINE.

Once any I/O operation has been requested on the port, an additional thread is started that keeps a read outstanding on the port so that data will not be missed.

The SPORT_SET_STATE, SPORT_SET_STATE_EX, and SPORT_SET_TIMEOUTS routines allow you to set basic port parameters such as baud rate, stop bits, timeouts, and so on. Additionally, you can call SPORT_GET_HANDLE to return the Windows* handle to the port so that you can call Windows* Communication Functions to implement additional needs.

Call the Serial Port I/O Routines

The SPORT_*xxx* routines are functions that return an error status:

- An error status of 0 (zero) indicates success
- Other values are Windows* error values that indicate an error

As described in the calling syntax, these routines require the following `USE` statement:

```
USE IFPORT
```

The `USE IFPORT` statement includes the routine definitions in the compilation. You may also need to add a `USE IFWINTY` statement to your program because some Windows* constants may be required that are typically defined in the IFWINTY module.

Many arguments are optional. If a constant is used where an argument is both input and output, a probe for writeability is done before the output. Thus, in many cases, a constant may be used without creating a temporary variable. It should be noted, however, that doing so may not be compatible with all Fortran implementations.

Runtime Behavior of the Serial Port I/O Routines

To help ensure that data overruns do not occur, the SPORT_*xxx* runtime support creates a separate thread that maintains an outstanding read to the connected port. This thread is started when any read or write operation is performed to the port using the affiliated read/write routine. As such, port parameters must not be changed after you have started reading or writing to the port. Instead, you should set up the port parameters after connecting to the port and then leave them unchanged until after the port has been released.

If the parameters of the port must be changed more dynamically, use the SPORT_CANCEL_IO routine to ensure that no I/O is in progress. Additionally, that call will kill the helper thread so that it will automatically pick up the new, correct, parameters when it restarts during the next I/O operation.

Serial Port Usage

Depending upon the application, serial port programming can be very simple or very complex . The SPORT_*xxx* routines are intended to provide a level of support that will help the user implement simple applications as well as providing a foundation that can be used for more complex applications. Users needing to implement full serial port protocols (such as a PPP/SLIP implementation or some other complex protocol) should use the Windows* Communication Functions directly to achieve the detailed level of control needed in those cases. Simple tasks, such as communicating with a terminal or some other data collection device are well suited for implementations using the SPORT_*xxx* routines.

You should first familiarize yourself with the hardware connection to the serial device. Typical connections used today involve either a 9 pin/wire connector or a 25 pin/wire connector. Many cables do not implement all 9 or 25 connections in order to save on costs. For certain applications these subset cables may work just fine but others may require the full 9 or 25 connections. All cables will implement the Receive/SendData signals as well as the SignalGround. Without these signals, there can be no data transfer. There are two other categories of important signals:

- Signals used for flow control

  Flow control signals tell the device/computer on the other end of the cable that data may be sent or that they should wait. Typically, the RequestToSend/ClearToSend signals are used for this purpose. Other signals such as DataSetReady or DataTerminalReady may also be used. Make sure that the cable used implements all the signals required by your hardware/software solution. Special characters (normally as XON/XOFF) may also be used to control the flow of data instead of or in addition to the hardware signals. Check your specific application to see what cabling is needed.
- Signals that indicate status or state of a modem or phone connection.

  These signals may not be required if the connection between the computer and the device is direct and not through a modem. This signals typically convey information such as the state of the carrier (CarrierDetect) or if the phone line is ringing (Ring). Again, make sure the cable used implements all the signals required for your application.

After the correct physical connection has been set up the programmer must become familiar with the data protocol used to communicate with the remote device/system.

Many simple devices terminate parcels of data with a "record terminator" (often a carriage return or line feed character). Other devices may simply send data in fixed length packets or packets containing some sort of count information. The two types of I/O routines provided by the SPORT_*xxx* support (line oriented using SPORT_READ_LINE and SPORT_WRITE_LINE or transfer raw data using SPORT_READ_DATA and SPORT_WRITE_DATA) can handle these two types of data transfer. The programmer must become familiar with the particular application to determine which type of I/O is more appropriate to use.

The SPORT_*xxx* routines call Windows* routines. For example, the SPORT_SET_STATE routine calls the routine SetCommState, which uses the DCB Communications Structure.

Portability Routines for a list of the SPORT routines

Summary of Language Extensions

This appendix summarizes the Intel© Fortran language extensions to the ANSI/ISO Fortran 2003 Standard.

Most extensions are available on all supported operating systems. However, some extensions are limited to one or more platforms. If an extension is limited, it is labeled.

Language Extensions: Source Forms

The following are extensions to the methods and rules for source forms:

- Tab-formatting as a method to code lines
- The letter D as a debugging statement indicator in column 1 of fixed or tab source form
- An optional statement field width of 132 columns for fixed or tab source form
- An optional sequence number field for fixed source form
- Up to 511 continuation lines in a source program

Language Extensions: Names

As an extension, the dollar sign ($) is a valid character in names, and can be the first character.

Language Extensions: Character Sets

The following are extensions to the standard character set:

- The Tab (<Tab>) character (see Character Sets)
- ASCII Character Code Chart 2 -- IBM* Character Set
- ANSI Character Code Chart
- Key Code Charts

Language Extensions: Intrinsic Data Types

The following are data-type extensions:

BYTE	INTEGER*1	REAL*16
DOUBLE COMPLEX	INTEGER*2	COMPLEX*8
LOGICAL*1	INTEGER*4	COMPLEX*16
LOGICAL*2	INTEGER*8	COMPLEX*32
LOGICAL*4	REAL*4	
LOGICAL*8	REAL*8	

See Also

Intrinsic Data Types

Language Extensions: Constants

Hollerith constants are allowed as an extension.

C Strings are allowed as extensions in character constants.

Language Extensions: Expressions and Assignment

When operands of different intrinsic data types are combined in expressions, conversions are performed as necessary (see Data Type of Numeric Expressions).

Binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

The following are extensions allowed in logical expressions:

- .XOR. as a synonym for .NEQV.
- Integers as valid logical items
- Logical operators applied to integers bit-by-bit

Language Extensions: Specification Statements

The following specification attributes and statements are extensions:

- AUTOMATIC attribute and statement
- STATIC attribute and statement

Language Extensions: Execution Control

The following control statements are extensions:

- ASSIGN
- Assigned GO TO
- IF - Arithmetic
- Non-block form of a DO statement
- PAUSE

These are older Fortran features that have been deleted from the Fortran Standard. Intel® Fortran fully supports these features.

Language Extensions: Compilation Control Lines and Statements

The following line option and statement are extensions that can influence compilation:

- [/[NO]LIST], which can be specified in an INCLUDE line
- The OPTIONS statement

Language Extensions: Built-In Functions

The following built-in functions are extensions:

- %VAL, %REF, and %LOC, which facilitate references to non-Fortran procedures
- %FILL, which can be used in record structure type definitions

Language Extensions: I/O Statements

The following I/O statements are extensions:

- The ACCEPT statement
- The REWRITE statement
- The TYPE statement, which is a synonym for the PRINT statement

Language Extensions: I/O Formatting

The following are extensions allowed in I/O Formatting:

- The Q edit descriptor
- The dollar sign ($) edit descriptor and carriage-control character
- The backslash (\) edit descriptor
- The ASCII NUL carriage-control character
- Variable format expressions
- The H edit descriptor

  This is an older Fortran feature that has been deleted in Fortran 95. Intel® Fortran fully supports this feature.

Language Extensions: File Operation Statements

The following statement specifiers and statements are extensions:

- CLOSE statement specifiers:
  - STATUS values: 'SAVE' (as a synonym for 'KEEP'), 'PRINT', 'PRINT/DELETE', 'SUBMIT', 'SUBMIT/DELETE'
  - DISPOSE (or DISP)
- DELETE statement
- INQUIRE statement specifiers:
  - BINARY (Windows)
  - BLOCKSIZE
  - BUFFERED
  - CARRIAGECONTROL
  - CONVERT
  - DEFAULTFILE
  - FORM values: 'UNKNOWN', 'BINARY' (Windows)
  - IOFOCUS (Windows)
  - MODE as a synonym for ACTION
  - ORGANIZATION
  - RECORDTYPE
  - SHARE (Windows)

  See also INQUIRE Statement.
- OPEN statement specifiers:
  - ACCESS values: 'APPEND'
  - ASSOCIATEVARIABLE
  - BLOCKSIZE
  - BUFFERCOUNT
  - BUFFERED
  - CARRIAGECONTROL
  - CONVERT
  - DEFAULTFILE
  - DISPOSE (or DISP)
  - FORM value: 'BINARY' (Windows)
  - IOFOCUS (Windows)
  - MAXREC
  - MODE as a synonym for ACTION
  - NAME as a synonym for FILE
  - NOSHARED
  - ORGANIZATION
  - READONLY
  - RECORDSIZE as a synonym for RECL
  - RECORDTYPE
  - SHARE (Windows)
  - SHARED
  - TITLE (Windows)
  - TYPE as a synonym for STATUS
  - USEROPEN

  See also OPEN Statement.

Language Extensions: Compiler Directives

The following General Directives are extensions:

- ALIAS
- ASSUME
- ASSUME_ALIGNED

- ATTRIBUTES
- BLOCK_LOOP and NOBLOCK_LOOP
- DECLARE and NODECLARE
- DEFINE and UNDEFINE
- DISTRIBUTE POINT
- FIXEDFORMLINESIZE
- FMA and NOFMA
- FORCEINLINE
- FREEFORM and NOFREEFORM
- IDENT
- IF and IF DEFINED
- INLINE and NOINLINE
- INTEGER
- IVDEP
- LOOP COUNT
- MESSAGE
- NOFUSION
- OBJCOMMENT
- OPTIMIZE and NOOPTIMIZE
- OPTIONS
- PACK
- PARALLEL and NOPARALLEL (loop)
- PREFETCH and NOPREFETCH
- PSECT
- REAL
- SIMD
- STRICT and NOSTRICT
- UNROLL and NOUNROLL
- UNROLL_AND_JAM and NOUNROLL_AND_JAM
- VECTOR and NOVECTOR

Language Extensions: Intrinsic Procedures

The following intrinsic procedures are extensions available on all platforms:

A to D

AIMIN0	BJTEST	CQEXP	DCOTAN
AJMAX0	BKTEST	CQLOG	DCOTAND
AJMIN0	BMOD	CQSIN	DERF
AKMAX0	BMVBITS	CQSQRT	DERFC
AKMIN0	BNOT	CQTAN	DFLOAT
AND	BSHFT	CTAN	DFLOTI
ASINH	BSHFTC	DACOSD	DFLOTJ
BABS	BSIGN	DACOSH	DFLOTK
BADDRESS	CACHESIZE	DASIND	DIMAG

Language Extensions: Additional Language Features

The following are language extensions that facilitate compatibility with other versions of Fortran:

- DEFINE FILE statement
- ENCODE and DECODE statements
- FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL statement
- An alternative syntax for the PARAMETER statement

- VIRTUAL statement
- AND, OR, XOR, IMAG, LSHIFT, RSHIFT intrinsics (see the *A to Z Reference*)
- An alternative syntax for octal and hexadecimal constants
- An alternative syntax for an I/O record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

Language Extensions: Runtime Library Routines

The following runtime library routines are available as extensions:

- Runtime Library Routines
- OpenMP* Runtime Library Routines for Fortran

A to Z Reference

This section contains the following:

- Language Summary Tables

  This section organizes the Fortran functions, subroutines, and statements by the operations they perform, and shows short descriptions of each routine. You can use the tables to locate a particular routine for a particular task.
- The descriptions of all Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.

  Certain routine groups, such as POSIX* routines and NLS routines, are in separate sections.

> **NOTE**
> In the description of routines, pointers and handles are INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.
>
> ifx does not generate code to run on IA-32 architecture.

The Fortran compiler understands statements and intrinsic functions in your program without any additional information, such as that provided in modules.

However, modules must be included in programs that contain the following routines. Note that the links in this list go to the relevant language summary table:

- Quickwin routines and graphics routines

  These routines require a USE IFQWIN statement to include the library and graphics modules.
- Portability routines

  It is recommended that you specify USE IFPORT when accessing routines in the portability library.
- Serial port I/O routines

  These routines require a USE IFPORT statement to access the portability library.
- NLS routines

  These routines require a USE IFNLS statement to access the NLS library.
- POSIX* routines

  These routines require a USE IFPOSIX statement to access the POSIX library.
- Dialog routines

  These routines require a USE IFLOGM statement to access the dialog library.
- Component Object Module (COM) routines

  These routines require a USE IFCOM statement to access the COM library.
- Automation server routines

These routines require a USE IFAUTO statement to access the AUTO library.

- Miscellaneous Runtime Routines

  Most of these routines require a USE IFCORE statement to obtain the proper interfaces.

When a USE module is required for a routine, it will be specified in the individual procedure description.

In addition to the appropriate USE statement, for some routines you must specify the types of libraries to be used when linking.

Language Summary Tables

This section contains tables that summarize language features such as statements, directives, and routines.

Statements for Program Unit Calls and Definitions

The following table lists statements used for program unit definition and procedure call and return.

Name	Description
BLOCK DATA	Identifies a block-data subprogram.
CALL	Executes a subroutine.
COMMON	Delineates variables shared between program units.
CONTAINS	Identifies the start of module procedures within a host module, contained procedures within a procedure, or bound procedures within a type.
ENTRY	Specifies a secondary entry point to a subroutine or external function.
EXTERNAL	Declares a name to be that of a user-defined subroutine or function, making it passable as an argument.
FUNCTION	Identifies a program unit as a function.
GENERIC	Specifies a generic identifier for one or more specific procedures or type bound procedures.
IMPORT	Makes entities from the host scoping unit accessible or inaccessible.
INCLUDE	Inserts the contents of a specified file into the source file. It is not considered a Fortran statement; it is referred to as an include line.
INTERFACE	Specifies an explicit interface for external functions and subroutines.
INTRINSIC	Declares a predefined function.
MODULE	Identifies a module program unit.
PROCEDURE	Declares procedure pointers, dummy procedures, external procedures, and type-bound procedures.
PROGRAM	Identifies a program unit as a main program.
RETURN	Returns control to the program unit that called a subroutine or function.
SUBROUTINE	Identifies a program unit as a subroutine.

Name	Description
USE	Gives a program unit access to a module.

Statements Affecting Variables

The following table lists statements that are used to declare variables of intrinsic and derived types, to declare new types, and that can affect the value of variables. Statements that declare variables can specify attributes of the variables. Attributes are listed in the table following this one.

Name	Description
ASSOCIATE[1]	Associates a name (alias) with a data designator or expression that can be used to identify that designator or expression in a block of code.
BYTE	Specifies variables as the BYTE data type; BYTE is equivalent to INTEGER(1).
CHARACTER	Specifies variables as the CHARACTER data type.
COMMON	Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program.
COMPLEX	Specifies variables as the COMPLEX data type.
DATA	Assigns initial values to variables.
DOUBLE COMPLEX	Specifies variables as the DOUBLE COMPLEX data type, equivalent to COMPLEX(8).
DOUBLE PRECISION	Specifies variables as the DOUBLE-PRECISION real data type, equivalent to REAL(8).
ENUM	Begins the definition of an interoperable enumeration and may give the type a name.
ENUMERATOR	Associates integer values with named constant enumerators.
EQUIVALENCE	Specifies that two or more variables or arrays share the same memory location.
FINAL	Indicates a derived type is finalizable and specifies what its final subroutines are.
IMPLICIT	Specifies the default types for variables and functions.
IMPLICIT NONE	Disables implicit typing in the scope, or requires all external procedures to have explicit interfaces if invoked from the scope.
INTEGER	Specifies variables as the INTEGER data type.
LOGICAL	Specifies variables as the LOGICAL data type.
MAP	Within a UNION statement, delimits a group of variable type declarations that are to be ordered contiguously within memory.

Name	Description
NAMELIST	Declares a group name for a set of variables to be read or written in a single statement.
NULLIFY[1]	Disassociates a variable with the POINTER attribute (sets it to NULL).
REAL	Specifies variables as the REAL data type.
RECORD	Declares one or more variables of a user-defined structure type.
SEQUENCE	Prevents the compiler from optimizing the storage order of components in a derived type.
STRUCTURE	Defines a new variable type, composed of a collection of other variable types.
TYPE	Defines a new variable type, composed of a collection of other variable types.
UNION	Within a structure, causes two or more maps to occupy the same memory locations.

[1] This is an executable statement.

The following table lists statements that give attributes to variables. Attributes also can be given to variables in their type declaration statement.

Name	Description
ALLOCATABLE	Indicates an entity can be dynamically allocated and deallocated.
ASYNCHRONOUS	Indicates a variable may be used in asynchronous input or output, or asynchronous communication.
AUTOMATIC	Declares a variable on the stack, rather than at a static memory location.
BIND	Indicates a variable or common block can interoperate with a C variable whose name has external linkage.
CODIMENSION	Specifies that an entity is a coarray and indicates its corank and cobounds, if any.
CONTIGUOUS	Indicates an array object is contiguous.
DIMENSION	Specifies that an entity is an array and indicates its rank and bounds.
EXTERNAL	Indicates an entity is an external procedure, a dummy procedure, a procedure pointer, or a block data subprogram.
INTENT	Indicates how a dummy argument is to be used: as an input argument (IN), an output argument (OUT), or as both input and output (INOUT).
INTRINSIC	Indicates an entity is an intrinsic procedure.

Name	Description
OPTIONAL	Indicates a dummy argument need not be associated with an actual argument in a procedure invocation.
PARAMETER	Equates a constant expression with a name.
POINTER	Indicates an entity can be associated with different data objects or procedures during the execution of a program. A pointer is either a data pointer or a procedure pointer, but not both.
PRIVATE	Limits the accessibility of a module entity by a particular name, or that of a component of a derived type declared in a module.
PROTECTED	Specifies limitations on the use of module entities.
PUBLIC	Makes a module entity accessible by USE association, or it makes a component of a derived type declared in a module accessible when the derived type is USE associated.
SAVE	Causes variables to retain their values between invocations of the procedure in which they are defined.
STATIC	Declares a variable is in a static memory location, rather than on the stack.
TARGET	Indicates a data object may become associated with a data pointer.
VALUE	Indicates a dummy argument is passed by value rather than by reference.
VOLATILE	Specifies that the value of an object is totally unpredictable based on information available to the current program unit.

Statements and Intrinsic Functions for Input and Output

The following table lists statements and intrinsic functions used for input and output.

Name	Procedure Type	Description
ACCEPT	Statement	Similar to a formatted, sequential READ statement.
BACKSPACE	Statement	Positions a file to the beginning of the previous record.
CLOSE	Statement	Disconnects the specified unit.
DELETE	Statement	Deletes a record from a relative file.
ENDFILE	Statement	Writes an end-of-file record or truncates a file.

Name	Procedure Type	Description
FLUSH	Statement	Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.
FORMAT	Statement	Associates a statement label with a sequence of format edit descriptors. The statement label is used in other input and output statements as the format specifier.
INQUIRE	Statement	Returns the properties of a file or unit.
IS_IOSTAT_END	Intrinsic function	Tests IOSTAT value for end of file.
IS_IOSTAT_EOR	Intrinsic function	Tests IOSTAT value for end of record.
OPEN	Statement	Associates a unit number with an external device or file.
PRINT(or TYPE)	Statement	Displays data on the screen.
READ	Statement	Transfers data from a file to the items in an I/O list.
REWIND	Statement	Repositions a file to its first record.
REWRITE	Statement	Rewrites the current record.
WRITE	Statement	Transfers data from the items in an I/O list to a file.

Compiler Directives

The following tables list available compiler directives.

Each OpenMP* Fortran directive name is preceded by the prefix !$OMP in free format source; in fixed format source the prefix is c$OMP, where c is one of the following: !, C (or c), or *; for example, !$OMP ATOMIC.

Directives that are extensions to OpenMP are preceded by the prefix !$OMPX in free format source; in fixed format source the prefix is *c*$OMP, where *c* is one of the following: !, C (or c), or *.

Compiler directives are specially formatted comments in the source file that provide information to the compiler. Some directives, such as line length or conditional compilation directives, provide the compiler information that is used in interpreting the source file. Other directives, such as optimization directives, provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler, based on the heuristics of the optimizer and/or code generator. If the directive is ignored by the compiler, no diagnostic message is issued.

You do not need to specify a compiler option to enable general directives.

Some directives may perform differently on Intel® microprocessors than on non-Intel microprocessors.

General Directives

Name	Description
ALIAS	Specifies an alternate external name to be used when referring to an external subprogram.
ASSUME	Provides heuristic information to the compiler optimizer.
ASSUME_ALIGNED	Specifies that an entity in memory is aligned.
ATTRIBUTES	Applies attributes to variables and procedures.
BLOCK_LOOP	Enables loop blocking for the immediately following nested DO loops.
DECLARE	Generates warning messages for undeclared variables.
DEFINE	Creates a variable whose existence can be tested during conditional compilation.
DISTRIBUTE POINT	Suggests a location at which a DO loop may be split.
ELSE	Marks the beginning of an alternative conditional-compilation block to an IF directive construct.
ELSEIF	Marks the beginning of an alternative conditional-compilation block to an IF directive construct.
ENDIF	Marks the end of a conditional-compilation block.
FIXEDFORMLINESIZE	Sets fixed-form line length. This directive has no effect on freeform code.
FMA	Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.
FORCEINLINE	Specifies that a routine should be inlined whenever the compiler can do so.
FREEFORM	Uses freeform format for source code.
IDENT	Specifies an identifier for an object module.
IF	Marks the beginning of a conditional-compilation block.
IF DEFINED	Marks the beginning of a conditional-compilation block.
INLINE	Specifies that the routines can be inlined.
INTEGER	Selects default integer size.
IVDEP	Assists the compiler's dependence analysis of iterative DO loops.

Name	Description
LOOP COUNT	Specifies the typical trip loop count for a DO loop; which assists the optimizer.
MESSAGE	Sends a character string to the standard output device.
NOBLOCK_LOOP	Disables loop blocking for the immediately following nested DO loops.
NODECLARE	(Default) Turns off warning messages for undeclared variables.
NOFMA	Disables the generation of FMA instructions.
NOFREEFORM	(Default) Uses standard FORTRAN 77 code formatting column rules.
NOFUSION	Prevents a loop from fusing with adjacent loops.
NOINLINE	Specifies that a routine should not be inlined.
NOPARALLEL	Disables auto-parallelization for an immediately following DO loop. This feature is only available for ifort.
NOOPTIMIZE	Disables optimizations for the program unit.
NOPREFETCH	Disables a data prefetch from memory.
NOSTRICT	(Default) Disables a previous STRICT directive.
NOUNROLL	Disables the unrolling of a DO loop.
NOUNROLL_AND_JAM	Disables loop unrolling and jamming.
NOVECTOR	Disables vectorization of a DO loop.
OBJCOMMENT	Specifies a library search path in an object file.
OPTIMIZE	Enables optimizations for the program unit.
OPTIONS	Controls whether fields in records and data items in common blocks are naturally aligned or packed on arbitrary byte boundaries.
PACK	Specifies the memory alignment of derived-type items.
PARALLEL	Helps auto-parallelization by assisting the compiler's dependence analysis of an immediately following DO loop. This feature is only available for ifort.
PREFETCH	Hints to the compiler to prefetch data from memory.
PSECT	Modifies certain characteristics of a common block.
REAL	Selects default real size.

Name	Description
SIMD	Requires and controls SIMD vectorization of loops. This feature is only available for ifort.
STRICT	Disables Intel® Fortran features not in the language standard specified on the command line.
UNDEFINE	Removes a symbolic variable name created with the DEFINE directive.
UNROLL	Tells the compiler's optimizer how many times to unroll a DO loop.
UNROLL_AND_JAM	Enables loop unrolling and jamming.
VECTOR	Overrides default heuristics for vectorization of DO loops.

OpenMP* Fortran Directives

OpenMP* directives are specially formatted Fortran comment lines embedded in the source file that provide the compiler with hints and suggestions for parallelization, optimization, vectorization, and offloading code to accelerator hardware.

The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

To use the following directives, you must specify compiler option `[q or Q]openmp`. For more information, refer to the option description in the Compiler Options reference.

Name	Description
ALLOCATE	Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.
ALLOCATORS	Specifies memory allocators to be used to allocate variables in the associated Fortran ALLOCATE statement and to use in their deallocation. This feature is only available for ifx.
ASSUMES	Provides hints to the optimizer about the current compilation unit and all the code it can reach through procedure calls. This feature is only available for ifx.
ATOMIC	Specifies that a specific memory location is to be updated atomically.
BARRIER	Synchronizes all the threads in a team.
CANCEL	Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

Name	Description
CANCELLATION POINT	Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.
CRITICAL	Restricts access for a block of code to only one thread at a time.
DECLARE MAPPER	Declares a user defined data mapper for derived types and local variables that can subsequently be used in MAP clauses. This feature is only available for ifx.
DECLARE REDUCTION	Declares a user defined reduction for one or more types.
DECLARE SIMD	Generates a SIMD procedure.
DECLARE TARGET	Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This feature is only available for ifx.
DECLARE VARIANT	Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.
DEPOBJ	Initializes, updates, or uninitializes an OpenMP depend object. This feature is only available for ifx.
DISPATCH	Determines if a variant of a procedure is called for a given function or subroutine call. This feature is only available for ifx.
DISTRIBUTE	Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.
DISTRIBUTE PARALLEL DO	Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
DISTRIBUTE PARALLEL DO SIMD	Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
DISTRIBUTE SIMD	Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.
DO	Specifies that the iterations of the immediately following DO loop must be executed in parallel.
DO SIMD	Specifies a loop that can be executed concurrently using SIMD instructions.

Name	Description
ERROR	Causes the compiler or runtime system to process an error condition. This feature is only available for ifx.
FLUSH	Specifies synchronization points where the implementation must have a consistent view of memory.
GROUPPRIVATE	Specifies that a variable is replicated once per group of threads participating in a parallel region. This feature is only available for ifx.
INTEROP	Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.
LOOP	Specifies that all iterations of the associated DO loop(s) can execute in any order or concurrently. This feature is only available for ifx.
MASKED	Specifies a block of code to be executed by a subset of threads of the current team. This feature is only available for ifx.
MASKED TASKLOOP	Provides an abbreviated way to specify a TASKLOOP construct inside a MASKED construct. This feature is only available for ifx.
MASKED TASKLOOP SIMD	Provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASKED construct. This feature is only available for ifx.
MASTER	(Deprecated, see MASKED) Specifies a block of code to be executed by the master thread of the team.
MASTER TASKLOOP	Deprecated; provides an abbreviated way to specify a TASKLOOP construct inside a MASTER construct. This feature is only available for ifx.
MASTER TASKLOOP SIMD	Deprecated; provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASTER construct. This feature is only available for ifx.
METADIRECTIVE	Specifies variant OpenMP directives, one of which may conditionally replace the metadirective based on the OpenMP context enclosing the metadirective. This feature is only available for ifx.
NOTHING	Provides documentary clarity in conditionally compiled code or conditional OpenMP* code. It has no effect on the semantics or execution of the program. This feature is only available for ifx.

Name	Description
ORDERED	Specifies a block of code to be executed sequentially.
PARALLEL	Defines a parallel region.
PARALLEL DO	Defines a parallel region that contains a single DO directive.
PARALLEL DO SIMD	Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.
PARALLEL LOOP	Provides an abbreviated way to specify a PARALLEL region containing a single LOOP construct and no other statements. This feature is only available for ifx.
PARALLEL MASKED	Provides an abbreviated way to specify a MASKED construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL MASKED TASKLOOP	Provides an abbreviated way to specify a MASKED TASKLOOP construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL MASKED TASKLOOP SIMD	Provides an abbreviated way to specify a MASKED TASKLOOP SIMD construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER	Deprecated; provides an abbreviated way to specify a MASTER construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP SIMD	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP SIMD construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.
PARALLEL SECTIONS	Defines a parallel region that contains SECTIONS directives.
PARALLEL WORKSHARE	Defines a parallel region that contains a single WORKSHARE directive.

Name	Description
PREFETCH DATA	Suggests to the compiler to preload data into cache. Preloading data in cache minimizes the effects of memory latency. This feature is only available for ifx.
REQUIRES	Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.
SCAN	Specifies a scan computation that updates each list item in each iteration of the loop.
SCOPE	Specifies a block of code to be executed by all threads of a team. This feature is only available for ifx.
SECTION	Appears within a SECTIONS construct to indicate a block (section) of code. This directive is optional for the first block of code within the SECTIONS construct.
SECTIONS	Specifies a block of code to be divided among threads in a team (a worksharing area).
SIMD	Requires and controls SIMD vectorization of loops.
SINGLE	Specifies a block of code to be executed by only one thread in a team.
TARGET	Creates a device data environment and executes the construct on the same device. This feature is only available for ifx.
TARGET DATA	Creates a device data environment for the extent of the region. This feature is only available for ifx.
TARGET ENTER DATA	Specifies that variables are mapped to a device data environment. This feature is only available for ifx.
TARGET EXIT DATA	Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.
TARGET PARALLEL	Creates a device data environment in a parallel region and executes the construct on that device.
TARGET PARALLEL DO	Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.
TARGET PARALLEL DO SIMD	Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

Name	Description
TARGET PARALLEL LOOP	Provides an abbreviated way to specify a TARGET region containing a single PARALLEL LOOP construct and no other statements. This feature is only available for ifx.
TARGET SIMD	Specifies a TARGET construct that contains a SIMD construct and no other statement.
TARGET TEAMS	Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.
TARGET TEAMS DISTRIBUTE	Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.
TARGET TEAMS DISTRIBUTE PARALLEL DO	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.
TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.
TARGET TEAMS DISTRIBUTE SIMD	Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.
TARGET TEAMS LOOP	Provides an abbreviated way to specify a TARGET region containing a single TEAMS LOOP construct and no other statements. This feature is only available for ifx.
TARGET UPDATE	Makes the list items in the device data environment consistent with their corresponding original list items. This feature is only available for ifx.
TASK	Defines a task region.
TASKGROUP	Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

Name	Description
TASKLOOP	Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.
TASKLOOP SIMD	Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.
TASKWAIT	Specifies a wait on the completion of child tasks generated since the beginning of the current task.
TASKYIELD	Specifies that the current task can be suspended in favor of execution of a different task.
TEAMS	Creates a league of thread teams inside a target region to execute a structured block in the primary thread of each team. This feature is only available for ifx.
TEAMS DISTRIBUTE	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.
TEAMS DISTRIBUTE PARALLEL DO	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
TEAMS DISTRIBUTE PARALLEL DO SIMD	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the primary threads of the teams region, which will be executed concurrently using SIMD instructions.
TEAMS DISTRIBUTE SIMD	Creates a league of thread teams to execute the structured block in the primary thread of each team. It also specifies a loop that will be distributed across the primary threads of the teams region. The loop will be executed concurrently using SIMD instructions.
TEAMS LOOP	Provides an abbreviated way to specify a TEAMS region containing a single LOOP construct and no other statements. This feature is only available for ifx.

Name	Description
THREADPRIVATE	Makes named common blocks private to a thread but global within the thread.
TILE	Tiles (or blocks) one or more loops in a loop nest. This feature is only available for ifx.
UNROLL	Partially or fully unrolls a DO loop. This feature is only available for ifx.
WORKSHARE	Divides the work of executing a block of statements or constructs into separate units.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Program Control Statements

The following table lists statements that affect program control.

Unless identified as an image control statement, the statement affects execution on a single image. With the exception of STOP, ERROR STOP, and END PROGRAM, image control statements are used with coarrays; they involve synchronization of images and they divide the program into segments.

Name	Description
ALLOCATE[1]	Allocates a coarray.
BLOCK[2]	Identifies a block of code. It can contain declarations of entities that are local to the block.
CALL	Transfers control to a subroutine.
CALL MOVE_ALLOC[1]	Relocates a coarray in memory.
CASE	Within a SELECT CASE construct, marks a block of statements that are executed if an associated value matches the SELECT CASE expression.
CASE DEFAULT or CLASS DEFAULT	Identifies the block of statements to be executed in a SELECT CASE construct if the value of the expression does not match any of the CASE selectors, or in a SELECT TYPE construct if the dynamic type of the selector does not match the type of any of the TYPE IS or CLASS IS statements.
CHANGE TEAM[3]	Causes images of the current team to begin execution on sibling (sub) teams as specified by a team variable created by a FORM_TEAM statement previous executed by the team encountering the CHANGE_TEAM statement.

Name	Description
CLASS IS	Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the CLASS IS expression.
CONTINUE	Often used as the target of GOTO or as the terminal statement in a DO loop; performs no operation.
CRITICAL[3]	Begins a critical construct. Only one image can execute the block of statements in the construct at a time.
CYCLE	Advances control to the end statement of a DO loop; the intervening loop statements are not executed.
DEALLOCATE[1]	Deallocates a coarray.
DO	Marks the beginning of a loop construct. Statements through and including the ending statement may be executed repeatedly.
DO CONCURRENT	Marks the beginning of a DO CONCURRENT construct. The order of executions of iterations of a DO CONCURRENT construct are indeterminate.
DO WHILE	Evaluates statements in the DO WHILE loop, through and including the ending statement, until a logical condition becomes .FALSE..
ELSE	Marks an optional branch in an IF construct.
ELSE IF	Marks an optional branch in an IF construct.
ELSEWHERE	Marks an optional branch in a WHERE construct.
END [PROGRAM][3]	Marks the end the main program. When executed, it initiates normal termination for the image that executes it.
END [FUNCTION] | [MODULE] | [SUBROUTINE][4]	Marks the end of a program unit.
END BLOCK[4]	Terminates a block construct.
END CRITICAL[3]	Terminates a critical construct.
END DO	Marks the end of a series of statements in a DO, DO CONCURRENT, or DO WHILE construct.
END FORALL	Marks the end of a series of statements following a block FORALL statement.
END IF	Marks the end of a series of statements following a block IF statement.
END SELECT	Marks the end of a SELECT CASE, SELECT RANK, or SELECT TYPE statement.
END TEAM[3]	Changes the current team to the parent team of the team of images that executes the END TEAM statement.

Name	Description
END WHERE	Marks the end of a series of statements following a block WHERE statement.
ERROR STOP	Initiates error termination for all images.
EVENT POST[3]	Increments the count of an event variable by one.
EVENT WAIT[3]	Tells the image executing this statement to wait until an event has been posted and to decrement the count of the event variable.
EXIT	Terminates execution of a DO loop or other construct. Execution continues with the first statement that follows the construct.
FAIL_IMAGE	Causes the image that executes it to execute no more statements and stop participating in program execution.
FORALL	Indicates a loop construct where the output from one iteration cannot change the input to another.
FORM TEAM[3]	Creates one or more subteams of the images in the current team and assigns a value describing the teams to a variable of type TEAM_TYPE, which is defined in the intrinsic module ISO_FORTRAN_ENV.
GOTO	Transfers control to a specified part of the program.
IF	Controls conditional execution of other statements.
LOCK[3]	Acquires a LOCK_TYPE variable, preventing other images from acquiring it until it has been unlocked by the image that locked it.
PAUSE	Suspends program execution and, optionally, executes operating-system commands.
RANK	Within a SELECT RANK construct, marks a block of statements that are executed if the rank of an assumed rank array matches the RANK selector.
RANK DEFAULT	Identifies the block of statements to be executed in a SELECT RANK construct if the rank of the array does not match any of the RANK selectors.
RETURN[4]	Returns control to the program unit that called a subroutine or function.
SELECT CASE	Transfers program control to a block of statements, determined by the value of an expression.
SELECT RANK	Transfers the program to a block of statements, determined by the rank of an assumed rank array.
SELECT TYPE	Transfers the program to a block of statements, determined by the dynamic type of an expression.
STOP	Initiates normal termination for the image that executes the statement.
SYNC ALL[3]	Synchronizes all of the images of the current team.

Name	Description
SYNC IMAGES[3]	Synchronizes an image with all of the specified images in the image set.
SYNC MEMORY[3]	Ends a segment and begins another; the two segments may be ordered in a user defined manner with respects to segments on other images.
SYNC TEAM[3]	Synchronizes all images on a specified team.
TYPE IS	Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the TYPE IS expression.
UNLOCK[3]	Unlocks a variable of type LOCK_TYPE.
WHERE	Controls conditional execution of array assignments and elemental function calls.

[1] This is an image control statement only if it involves a coarray; otherwise, it's not a program control statement.

[2] This is an image control statement only if the block declares a non-allocatable, non-SAVEd coarray.

[3] This is an image control statement

[4] This is an image control statement only if it involves implicit deallocation of a coarray.

Inquiry Intrinsic Functions

The following table lists inquiry intrinsic functions. Unless noted, inquiry intrinsic functions can be used in specification expressions.

Name	Description
ALLOCATED	Determines whether an allocatable variable is allocated.
ASSOCIATED	Determines if a pointer is associated or if two pointers are associated with the same target.
BIT_SIZE	Returns the number of bits in an integer type.
CACHESIZE	Returns the size of a level of the memory cache.
COSHAPE	Returns the sizes of codimensions of a coarray.
COMMAND_ARGUMENT_COUNT[1]	Returns the number of command-line arguments.
DIGITS	Returns number of significant digits for data of the same type as the argument.
EOF	Determines whether a file is at or beyond the end-of-file record.
EPSILON	Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.
EXTENDS_TYPE_OF	Determines if a derived type extends another derived type.

Name	Description
GET_TEAM[1]	Returns a variable of type TEAM_TYPE that describes a team of images that for the team inquired about. TEAM_TYPE is defined in the intrinsic module ISO_FORTRAN_ENV.
HUGE	Returns the largest number that can be represented by numbers of the type of the argument.
IARGC	Returns the index of the last command-line argument.
INT_PTR_KIND	Returns the INTEGER KIND that will hold an address.
IS_CONTIGUOUS	Returns whether an array is contiguous.
KIND	Returns the value of the kind parameter of the argument.
LBOUND	Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.
LCOBOUND	Returns the lower cobounds for all codimensions of a coarray, or the lower cobound for a specified codimension.
LEN	Returns the length of a character expression.
LOC[1]	Returns the address of the argument.
MAXEXPONENT	Returns the largest positive decimal exponent for data of the same type as the argument.
MINEXPONENT	Returns the largest negative decimal exponent for data of the same type as the argument.
NARGS	Returns the total number of command-line arguments, including the command.
NEW_LINE	Returns a newline character.
PRECISION	Returns the number of significant digits for data of the same type as the argument.
PRESENT	Determines whether an optional argument is present.
RADIX	Returns the base for data of the same type as the argument.
RANGE	Returns the decimal exponent range for data of the same type as the argument.
RANK	Returns the rank of a data object.
SAME_TYPE_AS	Determines if two polymorphic objects have the same dynamic type.
SELECTED_INT_KIND	Returns the value of the kind parameter of integers in range *r*.

Name	Description
SELECTED_REAL_KIND	Returns the value of the kind parameter of reals with (optional) first argument digits and (optional) second argument exponent range. At least one optional argument is required.
SHAPE	Returns the shape of an array or scalar argument.
SIZE	Returns the size of an array or the size of one extent of the array.
SIZEOF	Returns the number of bytes of storage used by the argument.
STORAGE_SIZE	Returns the number of bits occupied by an object.
TINY	Returns the smallest positive number that can be represented by numbers of type the argument.
UBOUND	Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.
UCOBOUND	Returns the upper cobounds for all codimensions of a coarray, or the upper cobound for a specified codimension.

[1] This function cannot be used in a specification expression because it is not a Fortran standard inquiry function.

Random Number Intrinsic Procedures

The following table lists random number intrinsic procedures.

Name	Procedure Type	Description
RAN	Intrinsic function	Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1.
RANF	Intrinsic function	Generates a random number between 0.0 and RAND_MAX.
RANDOM_INIT	Intrinsic subroutine	Initailizes the pseudorandom number generator used by RANDOM_NUMBER.
RANDOM_NUMBER	Intrinsic subroutine	Returns a pseudorandom real value greater than or equal to zero and less than one.
RANDOM_SEED	Intrinsic subroutine	Changes the starting point of RANDOM_NUMBER; takes one or no arguments.
RANDU	Intrinsic subroutine	Computes a pseudorandom number as a single-precision value.

The portability routines RANF, RANDOM, and SEED also supply this functionality.

Atomic Intrinsic Subroutines

The following table lists atomic intrinsic subroutines.

Atomic Operation

Name	Procedure Type	Description
ATOMIC_ADD	Intrinsic Subroutine	Performs atomic addition.
ATOMIC_AND	Intrinsic Subroutine	Performs atomic bitwise AND.
ATOMIC_CAS	Intrinsic Subroutine	Performs atomic compare and swap.
ATOMIC_DEFINE	Intrinsic Subroutine	Performs atomically defines a variable.
ATOMIC_FETCH_ADD	Intrinsic Subroutine	Performs atomic fetch and add.
ATOMIC_FETCH_AND	Intrinsic Subroutine	Performs atomic fetch and bitwise AND.
ATOMIC_FETCH_OR	Intrinsic Subroutine	Performs atomic fetch and bitwise OR.
ATOMIC_FETCH_XOR	Intrinsic Subroutine	Performs atomic fetch and bitwise exclusive OR.
ATOMIC_OR	Intrinsic Subroutine	Performs atomic bitwise OR.
ATOMIC_REF	Intrinsic Subroutine	Performs atomically references a variable.
ATOMIC_XOR	Intrinsic Subroutine	Performs atomic bitwise exclusive OR.

Collective Intrinsic Subroutines

The following table lists collective intrinsic subroutines.

Collective Operation

Name	Procedure Type	Description
CO_BROADCAST	Intrinsic Subroutine	Broadcasts a value to other images.
CO_MAX	Intrinsic Subroutine	Finds maximum value across images.
CO_MIN	Intrinsic Subroutine	Finds minimum value across images.
CO_REDUCE	Intrinsic Subroutine	Performs user-defined reduction across images.
CO_SUM	Intrinsic Subroutine	Performs sum reduction across images.

Date and Time Intrinsic Subroutines

The following table lists date and time intrinsic subroutines.

Name	Procedure Type	Description
CPU_TIME	Intrinsic subroutine	Returns the processor time in seconds.
DATE	Intrinsic subroutine	Returns the ASCII representation of the current date (in dd-mmm-yy form).
DATE_AND_TIME	Intrinsic subroutine	Returns the date and time. This is the preferred procedure for date and time.
IDATE	Intrinsic subroutine	Returns three integer values representing the current month, day, and year.
SYSTEM_CLOCK	Intrinsic subroutine	Returns data from the system clock.
TIME	Intrinsic subroutine	Returns the ASCII representation of the current time (in hh:mm:ss form).

The portability routines GETDAT, GETTIM, SETDAT, and SETTIM also supply this functionality.

Keyboard and Speaker Library Routines

The following table lists keyboard and speaker library routines.

Name	Routine Type	Description
GETCHARQQ	Runtime Function	Returns the next keyboard keystroke.
BEEPQQ	Portability subroutine	Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.
GETSTRQQ	Runtime function	Reads a character string from the keyboard using buffered input.
PEEKCHARQQ	Runtime function	Checks the buffer to see if a keystroke is waiting.

Statements and Intrinsic Procedures for Memory Allocation and Deallocation

The following table lists statements and intrinsic procedures that are used for memory allocation and deallocation.

Name	Procedure Type	Description
ALLOCATE	Statement	Dynamically establishes allocatable array dimensions.
ALLOCATED	Intrinsic Function	Determines whether an allocatable array is allocated.

Name	Procedure Type	Description
DEALLOCATE	Statement	Frees the storage space previously reserved in an ALLOCATE statement.
FREE	Intrinsic Subroutine	Frees the memory block specified by the integer pointer argument.
MALLOC	Intrinsic Function	Allocates a memory block of size bytes and returns an integer pointer to the block.
MOVE_ALLOC	Intrinsic Subroutine	Moves an allocation from one allocatable object to another.

Intrinsic Functions for Arrays and Coarrays

The following table lists intrinsic functions for arrays.

Name	Description
ALL	Determines whether all array values meet the conditions in a mask along a (optional) dimension.
ANY	Determines whether any array values meet the conditions in a mask along a (optional) dimension.
COUNT	Counts the number of array elements that meet the conditions in a mask along a (optional) dimension.
CSHIFT	Performs a circular shift along a (optional) dimension.
DOT_PRODUCT	Performs dot-product multiplication on vectors (one-dimensional arrays).
EOSHIFT	Shifts elements off one end of *array* along a (optional) dimension and copies (optional) boundary values in other end.
IALL	Reduces an array by the IAND function.
IANY	Reduces an array by the IOR function.
IPARITY	Reduces an array by the IEOR function.
LBOUND	Returns lower dimensional bounds of an array along a (optional) dimension.
MATMUL	Performs matrix multiplication on matrices (two-dimensional arrays).
MAXLOC	Returns the location of the maximum value in an array meeting conditions in a (optional) mask along a (optional) dimension.
MAXVAL	Returns the maximum value in an array along a (optional) dimension that meets conditions in a (optional) mask.
MERGE	Merges two arrays according to conditions in a mask.

Name	Description
MINLOC	Returns the location of the minimum value in an array meeting conditions in a (optional) mask along a (optional) dimension.
MINVAL	Returns the minimum value in an array along a (optional) dimension that meets conditions in a (optional) mask.
NORM2	Returns the L_2 norm of an array.
PACK	Packs an array into a vector (one-dimensional array) of a (optional) size using a mask.
PRODUCT	Returns product of elements of an array along a (optional) dimension that meet conditions in a (optional) mask.
RANK	Returns the rank of a data object.
REDUCE	Performs user-specified array reduction.
RESHAPE	Reshapes an array with (optional) subscript order, padded with (optional) array elements.
SHAPE	Returns the shape of an array.
SIZE	Returns the extent of an array along a (optional) dimension.
SPREAD	Replicates an array by adding a dimension.
SUM	Sums array elements along a (optional) dimension that meet conditions of an (optional) mask.
TRANSPOSE	Transposes a two-dimensional array.
UBOUND	Returns upper dimensional bounds of an array along a (optional) dimension.
UNPACK	Unpacks a vector (one-dimensional array) into an array under a mask padding with values from a field.

The following table lists intrinsic functions for coarrays.

Name	Description
COSHAPE	Returns the sizes of codimensions of a coarray.
EVENT_QUERY	Returns the event count.
FAILED_IMAGES	Returns the indices of images that are no longer responding.
IMAGE_INDEX	Returns the image index corresponding to an element of a coarray with a given set of cosubscripts.
IMAGE_STATUS	Returns the execution status of an image.
LCOBOUND	Returns the lower cobounds of a coarray.
NUM_IMAGES	Returns the number of images.

Name	Description
STOPPED_IMAGES	Returns the indices images that have initiated termination.
TEAM_NUMBER	Returns the team number of its argument.
THIS_IMAGE	Returns the index of the invoking image, or the cosubscripts for this image.
UCOBOUND	Returns the upper cobounds of a coarray.

Intrinsic Functions for Numeric and Type Conversion

The following table lists intrinsic functions for numeric and type conversion.

Name	Description
ABS	Returns the absolute value of the argument.
AIMAG	Returns imaginary part of complex number *z*.
AINT	Truncates the argument to a whole number of a specified (optional) kind.
AMAX0	Returns largest value among integer arguments as real.
AMIN0	Returns smallest value among integer arguments as real.
ANINT	Rounds to the nearest whole number of a specified (optional) kind.
CEILING	Returns smallest integer greater than the argument.
CMPLX	Converts the first argument and (optional) second argument to complex of a (optional) kind.
CONJG	Returns the conjugate of a complex number.
DBLE	Converts the argument to double precision type.
DCMPLX	Converts the argument to double complex type.
DFLOAT	Converts an integer to double precision type.
DIM	Returns the first argument minus the second argument if positive; else 0.
DPROD	Returns double-precision product of two single precision arguments.
FLOAT	Converts the argument to REAL(4).
FLOOR	Returns the greatest integer less than or equal to the argument.
IFIX	Converts a single-precision real argument to an integer argument by truncating.
IMAG	Same as AIMAG.

Name	Description
INT	Converts a value to integer type.
LOGICAL	Converts between logical arguments of (optional) kind.
MAX	Returns largest value among arguments.
MAX1	Returns largest value among real arguments as integer.
MIN	Returns smallest value among arguments.
MIN1	Returns smallest value among real arguments as integer
MOD	Returns the remainder of the first argument divided by the second argument.
MODULO	Returns the first argument modulo the second argument.
NINT	Returns the nearest integer to the argument.
NULL	Returns a disassociated pointer or an unallocated allocatable entity.
OUT_OF_RANGE	Indicates if a value can safely be converted to a specified type.
REAL	Converts a value to real type.
SIGN	Returns absolute value of the first argument times the sign of the second argument.
SNGL	Converts a double-precision argument to single-precision real type.
TRANSFER	Transforms first argument into type of second argument with (optional) size if an array.
ZEXT	Extends the argument with zeros.

Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures

The following table lists intrinsic procedures for trigonometric, exponential, root, and logarithmic operations.

NOTE
Many routines in the LIBM library (Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Name	Description
ACOS	Returns the arccosine of the argument, expressed in radians between 0 and pi.
ACOSD	Returns the arccosine of the argument, expressed in degrees between 0 and 180.
ALOG	Returns natural log of the argument.

Name	Description
ALOG10	Returns common log (base 10) of the argument.
ASIN	Returns the arcsine of the argument, expressed in radians between ±pi/2.
ASIND	Returns the arcsine of the argument, expressed in degrees between ±90°.
ATAN	Returns the arctangent of the argument, expressed in radians between ±pi/2.
ATAND	Returns the arctangent of the argument, expressed in degrees.
ATAN2	Returns the arctangent of the first argument divided by the second argument, expressed in radians between ±pi.
ATAN2D	Returns the arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.
CCOS	Returns complex cosine of the argument.
CDCOS	Returns the double-precision complex cosine of the argument.
CDEXP	Returns double-precision complex exponential value of the argument.
CDLOG	Returns the double-precision complex natural log of the argument.
CDSIN	Returns the double-precision complex sine of the argument.
CDSQRT	Returns the double-precision complex square root of the argument.
CEXP	Returns the complex exponential value of the argument.
CLOG	Returns the complex natural log of the argument.
COS	Returns the cosine of the argument, which is in radians.
COSD	Returns the cosine of the argument, which is in degrees.
COSH	Returns the hyperbolic cosine of the argument.
COTAN	Returns the cotangent of the argument, which is in radians.
COTAND	Returns the cotangent of the argument, which is in degrees.
CSIN	Returns the complex sine of the argument.
CSQRT	Returns the complex square root of the argument.

Name	Description
DACOS	Returns the double-precision arccosine of the argument radians between 0 and pi.
DACOSD	Returns the arccosine of the argument in degrees between 0 and 180.
DASIN	Returns the double-precision arcsine of the argument in radians between ±pi/2.
DASIND	Returns the double-precision arcsine of the argument degrees between ±90°.
DATAN	Returns the double-precision arctangent of the argument radians between ±pi/2.
DATAND	Returns the double-precision arctangent of the argument degrees between ±90°.
DATAN2	Returns the double-precision arctangent of the first argument divided by the second argument, expressed in radians between ±pi.
DATAN2D	Returns the double-precision arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.
DCOS	Returns the double-precision cosine of the argument, which is in radians.
DCOSD	Returns the double-precision cosine of the argument, which is in degrees.
DCOSH	Returns the double-precision hyperbolic cosine of the argument.
DCOTAN	Returns the double-precision cotangent of the argument.
DEXP	Returns the double-precision exponential value of the argument.
DLOG	Returns the double-precision natural log of the argument.
DLOG10	Returns the double-precision common log (base 10) of the argument.
DSIN	Returns the double-precision sin of the argument, whch is in radians.
DSIND	Returns the double-precision sin of the argument, which is in degrees.
DSINH	Returns the double-precision hyperbolic sine of the argument.
DSQRT	Returns the double-precision square root of the argument.
DTAN	Returns the double-precision tangent of the argument, which is in radians.

Name	Description
DTAND	Returns the double-precision tangent of the argument, which is in degrees.
DTANH	Returns the double-precision hyperbolic tangent of the argument.
EXP	Returns the exponential value of the argument.
EXP10	Returns the base 10 exponential value of the argument.
LOG	Returns the natural log of the argument.
LOG10	Returns the common log (base 10) of the argument.
SIN	Returns the sine of the argument, which is in radians.
SIND	Returns the sine of the argument, which is in degrees.
SINH	Returns the hyperbolic sine of the argument.
SQRT	Returns the square root of the argument.
TAN	Returns the tangent of the argument, which is in radians.
TAND	Returns the tangent of the argument, which is in degrees.
TANH	Returns the hyperbolic tangent of the argument.

Intrinsic Functions for Floating-Point Inquiry and Control

The following table lists intrinsic functions for floating-point inquiry and control.

Certain functions (EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, and SPACING) return values related to components of the model set of real numbers. For a description of this model, see the Model for Real Data.

Name	Description
DIGITS	Returns number of significant digits for data of the same type as the argument.
EPSILON	Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.
EXPONENT	Returns the exponent part of the representation of *x*.
FRACTION	Returns the fractional part of the representation of the argument.
HUGE	Returns largest number that can be represented by data of type the argument.
MAXEXPONENT	Returns the largest positive decimal exponent for data of the same type as the argument.

Name	Description
MINEXPONENT	Returns the largest negative decimal exponent for data of the same type as the argument.
NEAREST	Returns the nearest different machine representable number to the first argument in the direction of the sign of the second argument.
PRECISION	Returns the number of significant digits for data of the same type as the argument.
RADIX	Returns the base for data of the same type as the argument.
RANGE	Returns the decimal exponent range for data of the same type as the argument.
RRSPACING	Returns the reciprocal of the relative spacing of numbers near the argument.
SCALE	Multiplies the first argument by 2 raised to the power of the second argument.
SET_EXPONENT	Returns a number whose fractional part is the first argument and whose exponential part is the second argument.
SPACING	Returns the absolute spacing of numbers near the argument.
TINY	Returns smallest positive number that can be represented by data of type of the argument.

The portability routines GETCONTROLFPQQ, GETSTATUSFPQQ, LCWRQQ, SCWRQQ, SETCONTROLFPQQ, and SSWRQQ also supply this functionality.

Character Intrinsic Functions

The following table lists character intrinsic functions.

Name	Description
ACHAR	Returns character in a specified position in the ASCII character set.
ADJUSTL	Adjusts left, removing leading blanks and inserting trailing blanks.
ADJUSTR	Adjusts right, removing trailing blanks and inserting leading blanks.
CHAR	Returns character in a specified position in the processor's character set of (optional) kind.
IACHAR	Returns the position of the argument in the ASCII character set.
ICHAR	Returns the position of the argument in the processor's character set.
INDEX	Returns the starting position of a substring in a string, leftmost or (optional) rightmost occurance.

Name	Description
LEN	Returns the size of the argument.
LEN_TRIM	Returns the number of characters in the argument, not counting trailing blanks.
LGE	Tests whether the the first argument is greater than or equal to the second argument, based on the ASCII collating sequence.
LGT	Tests whether the first argument is greater than the second argument, based on the ASCII collating sequence.
LLE	Tests whether the first argument is less than or equal to the second argument, based on the ASCII collating sequence.
LLT	Tests whether the first argument is less than the second argument, based on the ASCII collating sequence.
REPEAT	Concatenates multiple copies of a string.
SCAN	Scans a string for any characters in a set and returns leftmost or (optional) rightmost position where a match is found.
TRIM	Removes trailing blanks from a string.
VERIFY	Returns the position of the leftmost or (optional) rightmost character in the argument string not in a set, or zero if all characters in the set are present.

Intrinsic Procedures for Bit Operation and Representation

The following tables list intrinsic procedures for bit operation and representation.

Bit Operation

Name	Procedure Type	Description
BIT_SIZE	Intrinsic Function	Returns the number of bits in integers of the type the argument.
BTEST	Intrinsic Function	Tests a bit in a position of the argument; true if bit is 1.
IAND	Intrinsic Function	Performs a logical AND.
IBCHNG	Intrinsic Function	Reverses value of bit in a position of the argument.
IBCLR	Intrinsic Function	Clears the bit in a position of the argument to zero.

Name	Procedure Type	Description
IBITS	Intrinsic Function	Extracts a sequence of bits of length from the argument starting in a position.
IBSET	Intrinsic Function	Sets the bit in a position of the argument to one.
IEOR	Intrinsic Function	Performs an exclusive OR.
IOR	Intrinsic Function	Performs an inclusive OR.
ISHA	Intrinsic Function	Shifts the argument arithmetically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from the right, ones shifted in from the left.
ISHC	Intrinsic Function	Performs a circular shift of the argument left or right by shift bits; left if shift positive, right if shift negative. No bits lost.
ISHFT	Intrinsic Function	Shifts the argument logically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from opposite end.
ISHFTC	Intrinsic Function	Performs a circular shift of the rightmost bits of (optional) size by shift bits. No bits lost.
ISHL	Intrinsic Function	Shifts the argument logically left or right by shift bits. Zeros shifted in from opposite end.
MVBITS	Intrinsic Subroutine	Copies a sequence of bits from one integer to another.
NOT	Intrinsic Function	Performs a logical complement.

Bit Representation

Name	Procedure Type	Description
LEADZ	Intrinsic Function	Returns leading zero bits in an integer.

Name	Procedure Type	Description
POPCNT	Intrinsic Function	Returns number of 1 bits in an integer.
POPPAR	Intrinsic Function	Returns the parity of an integer.
TRAILZ	Intrinsic Function	Returns trailing zero bits in an integer.

QuickWin Library Routines Summary

The following table lists Quickwin library routines.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

Name	Routine Type	Description
ABOUTBOXQQ	Function	Adds an About Box with customized text.
APPENDMENUQQ	Function	Appends a menu item.
CLICKMENUQQ	Function	Sends menu click messages to the application window.
DELETEMENUQQ	Function	Deletes a menu item.
FOCUSQQ	Function	Makes a child window active, and gives focus to the child window.
GETACTIVEQQ	Function	Gets the unit number of the active child window.
GETEXITQQ	Function	Gets the setting for a QuickWin application's exit behavior.
GETHWNDQQ	Function	Gets the true windows handle from window with the specified unit number.
GETWINDOWCONFIG	Function	Returns the current window's properties.
GETWSIZEQQ	Function	Gets the size of the child or frame window.
GETUNITQQ	Function	Gets the unit number corresponding to the specified windows handle. Inverse of GETHWNDQQ.
INCHARQQ	Function	Reads a keyboard input and return its ASCII value.
INITIALSETTINGS	Function	Controls initial menu settings and initial frame window settings.
INQFOCUSQQ	Function	Determines which window is active and has the focus.
INSERTMENUQQ	Function	Inserts a menu item.

Name	Routine Type	Description
INTEGERTORGB	Subroutine	Converts a true color value into its red, green and blue components.
MESSAGEBOXQQ	Function	Displays a message box.
MODIFYMENUFLAGSQQ	Function	Modifies a menu item state.
MODIFYMENUROUTINEQQ	Function	Modifies a menu item's callback routine.
MODIFYMENUSTRINGQQ	Function	Changes a menu item's text string.
PASSDIRKEYSQQ	Function	Determines the behavior of direction and page keys.
REGISTERMOUSEEVENT	Function	Registers the application-defined routines to be called on mouse events.
RGBTOINTEGER	Function	Converts a trio of red, green and blue values to a true color value for use with RGB functions and subroutines.
SETACTIVEQQ	Function	Makes the specified window the current active window without giving it the focus.
SETEXITQQ	Function	Sets a QuickWin application's exit behavior.
SETMESSAGEQQ	Subroutine	Changes any QuickWin message, including status bar messages, state messages and dialog box messages.
SETMOUSECURSOR	Function	Sets the mouse cursor for the window in focus.
SETWINDOWCONFIG	Function	Configures the current window's properties.
SETWINDOWMENUQQ	Function	Sets the Window menu to which current child window names will be appended.
SETWSIZEQQ	Function	Sets the size of the child or frame window.
UNREGISTERMOUSEEVENT	Function	Removes the callback routine registered by REGISTERMOUSEEVENT.
WAITONMOUSEEVENT	Function	Blocks return until a mouse event occurs.

Graphics Library Routines Summary

The following table lists library routines for graphics.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

Name	Routine Type	Description
ARC, ARC_W	Functions	Draws an arc.
CLEARSCREEN	Subroutine	Clears the screen, viewport, or text window.
DISPLAYCURSOR	Function	Turns the cursor off and on.
ELLIPSE, ELLIPSE_W	Functions	Draws an ellipse or circle.
FLOODFILL, FLOODFILL_W	Functions	Fills an enclosed area of the screen with the current color index, using the current fill mask.
FLOODFILLRGB, FLOODFILLRGB_W	Functions	Fills an enclosed area of the screen with the current RGB color, using the current fill mask.
GETARCINFO	Function	Determines the end points of the most recently drawn arc or pie.
GETBKCOLOR	Function	Returns the current background color index.
GETBKCOLORRGB	Function	Returns the current background RGB color.
GETCOLOR	Function	Returns the current color index.
GETCOLORRGB	Function	Returns the current RGB color.
GETCURRENTPOSITION, GETCURRENTPOSITION_W	Subroutines	Returns the coordinates of the current graphics-output position.
GETFILLMASK	Subroutine	Returns the current fill mask.
GETFONTINFO	Function	Returns the current font characteristics.
GETGTEXTEXTENT	Function	Determines the width of the specified text in the current font.
GETGTEXTROTATION	Function	Get the current text rotation angle.
GETIMAGE, GETIMAGE_W	Subroutines	Stores a screen image in memory.
GETLINESTYLE	Function	Returns the current line style.
GETLINEWIDTHQQ	Function	Returns the current line width or the line width set by the last call to SETLINEWIDTHQQ.
GETPHYSCOORD	Subroutine	Converts viewport coordinates to physical coordinates.
GETPIXEL, GETPIXEL_W	Functions	Returns a pixel's color index.
GETPIXELRGB, GETPIXELRGB_W	Functions	Returns a pixel's RGB color.

Name	Routine Type	Description
GETPIXELS	Function	Returns the color indices of multiple pixels.
GETPIXELSRGB	Function	Returns the RGB colors of multiple pixels.
GETTEXTCOLOR	Function	Returns the current text color index.
GETTEXTCOLORRGB	Function	Returns the current text RGB color.
GETTEXTPOSITION	Subroutine	Returns the current text-output position.
GETTEXTWINDOW	Subroutine	Returns the boundaries of the current text window.
GETVIEWCOORD, GETVIEWCOORD_W	Subroutines	Converts physical or window coordinates to viewport coordinates.
GETWINDOWCOORD	Subroutine	Converts viewport coordinates to window coordinates.
GETWRITEMODE	Function	Returns the logical write mode for lines.
GRSTATUS	Function	Returns the status (success or failure) of the most recently called graphics routine.
IMAGESIZE, IMAGESIZE_W	Functions	Returns image size in bytes.
INITIALIZEFONTS	Function	Initializes the font library.
LINETO, LINETO_W	Functions	Draws a line from the current position to a specified point.
LINETOAR	Function	Draws a line between points in one array and corresponding points in another array.
LINETOAREX	Function	Similar to LINETOAR, but also lets you specify color and line style.
LOADIMAGE, LOADIMAGE_W	Functions	Reads a Windows bitmap file (.BMP) and displays it at the specified location.
MOVETO, MOVETO_W	Subroutines	Moves the current position to the specified point.
OUTGTEXT	Subroutine	Sends text in the current font to the screen at the current position.
OUTTEXT	Subroutine	Sends text to the screen at the current position.
PIE, PIE_W	Functions	Draws a pie slice.

Name	Routine Type	Description
POLYBEZIER, POLYBEZIER_W	Functions	Draws one or more Bezier curves.
POLYBEZIERTO, POLYBEZIERTO_W	Functions	Draws one or more Bezier curves.
POLYGON, POLYGON_W	Functions	Draws a polygon.
POLYLINEQQ	Function	Draws a line between successive points in an array.
PUTIMAGE, PUTIMAGE_W	Subroutines	Retrieves an image from memory and displays it.
RECTANGLE, RECTANGLE_W	Functions	Draws a rectangle.
REMAPALLPALETTERGB	Function	Remaps a set of RGB color values to indices recognized by the current video configuration.
REMAPPALETTERGB	Function	Remaps a single RGB color value to a color index.
SAVEIMAGE, SAVEIMAGE_W	Functions	Captures a screen image and saves it as a Windows bitmap file.
SCROLLTEXTWINDOW	Subroutine	Scrolls the contents of a text window.
SETBKCOLOR	Function	Sets the current background color.
SETBKCOLORRGB	Function	Sets the current background color to a direct color value rather than an index to a defined palette.
SETCLIPRGN	Subroutine	Limits graphics output to a part of the screen.
SETCOLOR	Function	Sets the current color to a new color index.
SETCOLORRGB	Function	Sets the current color to a direct color value rather than an index to a defined palette.
SETFILLMASK	Subroutine	Changes the current fill mask to a new pattern.
SETFONT	Function	Finds a single font matching the specified characteristics and assigns it to OUTGTEXT.
SETGTEXTROTATION	Subroutine	Sets the direction in which text is written to the specified angle.
SETLINESTYLE	Subroutine	Changes the current line style.
SETLINEWIDTHQQ	Subroutine	Sets the width of a solid line drawn using any of the supported graphics functions.

Name	Routine Type	Description
SETPIXEL, SETPIXEL_W	Functions	Sets color of a pixel at a specified location.
SETPIXELRGB, SETPIXELRGB_W	Functions	Sets RGB color of a pixel at a specified location.
SETPIXELS	Subroutine	Sets the color indices of multiple pixels.
SETPIXELSRGB	Subroutine	Sets the RGB color of multiple pixels.
SETTEXTCOLOR	Function	Sets the current text color to a new color index.
SETTEXTCOLORRGB	Function	Sets the current text color to a direct color value rather than an index to a defined palette.
SETTEXTCURSOR	Function	Sets the height and width of the text cursor for the window in focus.
SETTEXTPOSITION	Subroutine	Changes the current text position.
SETTEXTWINDOW	Subroutine	Sets the current text display window.
SETVIEWORG	Subroutine	Positions the viewport coordinate origin.
SETVIEWPORT	Subroutine	Defines the size and screen position of the viewport.
SETWINDOW	Function	Defines the window coordinate system.
SETWRITEMODE	Function	Changes the current logical write mode for lines.
WRAPON	Function	Turns line wrapping on or off.

Portability Library Routines

The following tables list library routines for portability.

If you have programs that use these routines, it is recommended that they access the portability library with USE IFPORT.

Some routines in this library can be called with different sets of arguments, and some can be used as a function or a subroutine. In these cases, the arguments and calling mechanism determine the meaning of the routine. The IFPORT module contains generic interface blocks that give procedure definitions for these routines.

Fortran contains intrinsic procedures for many of the portability functions. The portability routines are extensions to the Fortran 2018 standard. For portability and performance, you should write code using Fortran standard intrinsic procedures whenever possible.

Information Retrieval

Name	Procedure Type	Description
FOR_IFCORE_VERSION	Function	Returns the version of the Fortran runtime library (ifcore).
FOR_IFPORT_VERSION	Function	Returns the version of the Fortran portability library (ifport).
FSTAT	Function	Returns information about a logical file unit.
GETCWD	Function	Returns the pathname of the current working directory.
GETENV	Subroutine	Searches the environment for a given string and returns its value if found.
GETGID	Function	Returns the group ID of the user.
GETLOG	Subroutine	Returns the user's login name.
GETPID	Function	Returns the process ID of the process.
GETUID	Function	Returns the user ID of the user of the process.
HOSTNAM[1]	Function	Returns the name of the user's host.
ISATTY	Function	Checks whether a logical unit number is a terminal.
LSTAT	Function	Returns information about a named file. STAT is the preferred form of this function.
RENAME	Function	Renames a file.
STAT	Function	Returns information about a named file.
UNLINK	Function	Deletes the file given by path.

Process Control

Name	Procedure Type	Description
ABORT	Subroutine	Stops execution of the current process, clears I/O buffers, and writes a string to external unit 0.
ALARM	Function	Executes an external subroutine after waiting a specified number of seconds.
KILL	Function	Sends a signal code to the process given by ID.
SIGNAL	Function	Changes the action for signal.
SLEEP	Subroutine	Suspends program execution for a specified number of seconds.

Name	Procedure Type	Description
SYSTEM	Function	Executes a command in a separate shell.

Numeric Values and Conversion

Name	Procedure Type	Description
BESJ0, BESJ1,BESJN, BESY0,BESY1, BESYN	Functions	Return single-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.
BIC, BIS	Subroutines	Perform bit level clear, set, and test for integers.
BIT	Function	Performs bit level clear, set, and test for integers.
CDFLOAT	Function	Converts a COMPLEX(4) argument to DOUBLE PRECISION type.
COMPLINT, COMPLREAL, COMPLLOG	Functions	Return a BIT-WISE complement or logical .NOT. of the argument.
CSMG	Function	Performs an effective BIT-WISE store under mask.
DBESJ0, DBESJ1,DBESJN, DBESY0,DBESY1, DBESYN	Functions	Return double-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.
DFLOATI, DFLOATJ, DFLOATK	Functions	Convert an integer to double-precision real type.
DRAND, DRANDM	Functions	Return random numbers between 0.0 and 1.0.
DRANSET	Subroutine	Sets the seed for the random number generator.
IDFLOAT	Function	Converts an INTEGER(4) argument to double-precision real type.
IFLOATI, IFLOATJ	Functions	Convert an integer to single-precision real type.
INMAX	Function	Returns the maximum positive value for an integer.
INTC	Function	Converts an INTEGER(4) argument to INTEGER(2) type.
IRAND, IRANDM	Functions	Return a positive integer in the range 0 through 2**31-1 or 2**15-1 if called without an argument.
IRANGET	Subroutine	Returns the current seed.

Name	Procedure Type	Description
IRANSET	Subroutine	Sets the seed for the random number generator.
JABS	Function	Computes an absolute value.
LONG	Function	Converts an INTEGER(2) argument to INTEGER(4) type.
QRANSET	Subroutine	Sets the seed for a sequence of pseudo-random numbers.
RAND, RANDOM[2]	Functions	Return random values in the range 0 through 1.0.
RANF	Function	Generates a random number between 0.0 and RAND_MAX.
RANGET	Subroutine	Returns the current seed.
RANSET	Subroutine	Sets the seed for the random number generator.
SEED	Subroutine	Changes the starting point of RANDOM.
SHORT	Function	Converts an INTEGER(4) argument to INTEGER(2) type.
SRAND	Subroutine	Seeds the random number generator used with IRAND and RAND.

Input and Output

Name	Procedure Type	Description
ACCESS	Function	Checks a file for accessibility according to mode.
CHMOD	Function	Changes file attributes.
FGETC	Function	Reads a character from an external unit.
FLUSH	Function	Flushes the buffer for an external unit to its associated file.
FPUTC	Function	Writes a character to an external unit.
FSEEK	Subroutine	Repositions a file on an external unit.
FTELL, FTELLI8	Function	Return the offset, in bytes, from the beginning of the file.
GETC	Function	Reads a character from unit 5.
GETPOS, GETPOSI8	Functions	Return the offset, in bytes, from the beginning of the file.
PUTC	Function	Writes a character to unit 6.

Date and Time

Name	Procedure Type	Description
CLOCK	Function	Returns current time in HH:MM:SS format using a 24-hour clock.
CLOCKX	Subroutine	Returns the processor clock to the nearest microsecond.
CTIME	Function	Converts system time to a 24-character ASCII string.
DATE[3]	Subroutine or Function	Returns the current system date.
DATE4	Subroutine	Returns the current system date.
DCLOCK	Function	Returns the elapsed time in seconds since the start of the current process.
DTIME	Function	Returns CPU time since later of (1) start of program, or (2) most recent call to DTIME.
ETIME	Function	Returns elapsed CPU time since the start of program execution.
FDATE	Subroutine or Function	Returns the current date and time as an ASCII string.
GETDAT	Subroutine	Returns the date.
GETTIM	Subroutine	Returns the time.
GMTIME	Subroutine	Returns Greenwich Mean Time as a 9-element integer array.
IDATE[3]	Subroutine	Returns the date either as one 3-element array or three scalar parameters (month, day, year).
IDATE4	Subroutine	Returns the date either as one 3-element array or three scalar parameters (month, day, year).
ITIME	Subroutine	Returns current time as a 3-element array (hour, minute, second).
JDATE[3]	Function	Returns current date as an 8-character string with the Julian date.
JDATE4	Function	Returns current date as a 10-character string with the Julian date.
LTIME	Subroutine	Returns local time as a 9-element integer array.
RTC	Function	Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.

Name	Procedure Type	Description
SECNDS	Function	Returns number of seconds since midnight, less the value of its argument.
SETDAT	Function	Sets the date.
SETTIM	Function	Sets the time.
TIME	Subroutine or Function	As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.
TIMEF	Function	Returns the number of seconds since the first time this function was called (or zero).

Error Handling

Name	Procedure Type	Description
GETLASTERROR	Function	Returns the last error set.
GETLASTERRORQQ	Function	Returns the last error set by a runtime function or subroutine.
IERRNO	Function	Returns the last code error.
SETERRORMODEQQ	Subroutine	Sets the mode for handling critical errors.

Program Control

Name	Procedure Type	Description
RAISEQQ	Function	Sends an interrupt to the executing program, simulating an interrupt from the operating system.
RUNQQ	Function	Calls another program and waits for it to execute.
SIGNALQQ	Function	Controls signal handling.
SLEEPQQ	Subroutine	Delays execution of the program for the specified time.

System, Drive, and Directory

Name	Procedure Type	Description
CHDIR	Function	Changes the current working directory.
CHANGEDIRQQ	Function	Makes the specified directory the current (default) directory.
CHANGEDRIVEQQ	Function	Makes the specified drive the current drive.
DELDIRQQ	Function	Deletes a specified directory.

Name	Procedure Type	Description
GETDRIVEDIRQQ	Function	Returns the current drive and directory path.
GETDRIVESIZEQQ	Function	Gets the size of the specified drive.
GETDRIVESQQ	Function	Reports the drives available to the system.
GETENVQQ	Function	Gets a value from the current environment.
MAKEDIRQQ	Function	Makes a directory with the specified directory name.
SETENVQQ	Function	Adds a new environment variable, or sets the value of an existing one.
SYSTEMQQ	Function	Executes a command by passing a command string to the operating system's command interpretor.

Speaker

Name	Procedure Type	Description
BEEPQQ	Subroutine	Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.

File Management

Name	Procedure Type	Description
DELFILESQQ	Function	Deletes the specified files in a specified directory.
FINDFILEQQ	Function	Searches for a file in the directories specified in the PATH environment variable.
FULLPATHQQ	Function	Returns the full path for a specified file or directory.
GETFILEINFOQQ	Function	Returns information about files with names that match a request string.
PACKTIMEQQ	Subroutine	Packs time values for use by SETFILETIMEQQ.
RENAMEFILEQQ	Function	Renames a file.
SETFILEACCESSQQ	Function	Sets file-access mode for the specified file.
SETFILETIMEQQ	Function	Sets modification time for a given file.
SPLITPATHQQ	Function	Breaks a full path into four components.

Name	Procedure Type	Description
UNPACKTIMEQQ	Subroutine	Unpacks a file's packed time and date value into its component parts.

Arrays

Name	Procedure Type	Description
BSEARCHQQ	Function	Performs a binary search for a specified element on a sorted one-dimensional array of non-structure data types (derived types are not allowed).
SORTQQ	Subroutine	Sorts a one-dimensional array of non-structure data types (derived types are not allowed).

Floating-Point Inquiry and Control

Name	Procedure Type	Description
CLEARSTATUSFPQQ	Subroutine	Clears the exception flags in the floating-point processor status word.
GETCONTROLFPQQ	Subroutine	Returns the value of the floating-point processor control word.
GETSTATUSFPQQ	Subroutine	Returns the value of the floating-point processor status word.
LCWRQQ	Subroutine	Same as SETCONTROLFPQQ.
SCWRQQ	Subroutine	Same as GETCONTROLFPQQ.
SETCONTROLFPQQ	Subroutine	Sets the value of the floating-point processor control word.
SSWRQQ	Subroutine	Same as GETSTATUSFPQQ.

IEEE Functionality

Name	Procedure Type	Description
IEEE_FLAGS	Function	Sets, gets, or clears IEEE flags.
IEEE_HANDLER	Function	Establishes a handler for IEEE exceptions.

Serial Port I/O[4]

Name	Procedure Type	Description
SPORT_CANCEL_IO	Function	Cancels any I/O in progress to the specified port.
SPORT_CONNECT	Function	Establishes the connection to a serial port and defines certain usage parameters.

Name	Procedure Type	Description
SPORT_CONNECT_EX	Function	Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.
SPORT_GET_HANDLE	Function	Returns the Windows* handle associated with the communications port.
SPORT_GET_STATE	Function	Returns the baud rate, parity, data bits, and stop bit settings of the communications port.
SPORT_GET_STATE_EX	Function	Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.
SPORT_GET_TIMEOUTS	Function	Returns the user selectable timeouts for the serial port.
SPORT_PEEK_DATA	Function	Returns information about the availability of input data.
SPORT_PEEK_LINE	Function	Returns information about the availability of input records.
SPORT_PURGE	Function	Executes a purge function on the specified port.
SPORT_READ_DATA	Function	Reads available data from the port specified.
SPORT_READ_LINE	Function	Reads a record from the port specified.
SPORT_RELEASE	Function	Releases a serial port that has previously been connected.
SPORT_SET_STATE	Function	Sets the baud rate, parity, data bits and stop bit settings of the communications port.
SPORT_SET_STATE_EX	Function	Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.
SPORT_SET_TIMEOUTS	Function	Sets the user selectable timeouts for the serial port.
SPORT_SHOW_STATE	Function	Displays the state of a port.
SPORT_SPECIAL_FUNC	Function	Executes a communications function on a specified port.
SPORT_WRITE_DATA	Function	Outputs data to a specified port.
SPORT_WRITE_LINE	Function	Outputs data to a specified port and follows it with a record terminator.

Miscellaneous

Name	Procedure Type	Description
LNBLNK	Function	Returns the index of the last non-blank character in a string.
QSORT	Subroutine	Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.
RINDEX	Function	Returns the index of the last occurrence of a substring in a string.
SCANENV	Subroutine	Scans the environment for the value of an environment variable.
TTYNAM	Subroutine	Checks whether a logical unit is a terminal.

[1] This routine can also be specified as HOSTNM.

[2] There is also a RANDOM subroutine in the portability library.

[3] The two-digit year return value of DATE, IDATE, and JDATE may cause problems with the year 2000. Use the intrinsic subroutine DATE_AND_TIME instead.

[4] Windows

National Language Support Library Routines Summary

The following table lists library routines for National Language Support (NLS).

Programs that use these routines must access the NLS library with USE IFNLS. These routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

Name	Routine Type	Description
MBCharLen	Function	Returns the length of the first multibyte character in a string.
MBConvertMBToUnicode	Function	Converts a character string from a multibyte codepage to a Unicode string.
MBConvertUnicodeToMB	Function	Converts a Unicode string to a multibyte character string of the current codepage.
MBCurMax	Function	Returns the longest possible mutlibyte character for the current codepage.
MBINCHARQQ	Function	Same as INCHARQQ, but can read a single multibyte character at once.
MBINDEX	Function	Same as INDEX, except that multibyte characters can be included in its arguments.

Name	Routine Type	Description
MBJISToJMS	Function	Converts a Japan Industry Standard (JIS) character to a Kanji (Shift JIS or JMS) character.
MBJMSToJIS	Function	Converts a Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.
MBLead	Function	Determines whether a given character is the first byte of a multibyte character.
MBLen	Function	Returns the number of multibyte characters in a string, including trailing spaces.
MBLen_Trim	Function	Returns the number of multibyte characters in a string, not including trailing spaces.
MBLGE, MBLGT, MBLLE, MBLLT,MBLEQ, MBLNE	Function	Same as LGE, LGT, LLE, and LLT, and the logical operators .EQ. and .NE., except that multibyte characters can be included in their arguments.
MBNext	Function	Returns the string position of the first byte of the multibyte character immediately after the given string position.
MBPrev	Function	Returns the string position of the first byte of the multibyte character immediately before the given string position.
MBSCAN	Function	Same as SCAN, except that multibyte characters can be included. in its arguments
MBStrLead	Function	Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.
MBVERIFY	Function	Same as VERIFY, except that multibyte characters can be included in its arguments.
NLSEnumCodepages	Function	Returns an array of valid codepages for the current console.
NLSEnumLocales	Function	Returns an array of locales (langauge/country combinations) installed on the system.

Name	Routine Type	Description
NLSFormatCurrency	Function	Formats a currency number according to conventions of the current locale (language/country).
NLSFormatDate	Function	Formats a date according to conventions of the current locale (language/country).
NLSFormatNumber	Function	Formats a number according to conventions of the current locale (language/country).
NLSFormatTime	Function	Formats a time according to conventions of the current locale (language/country).
NLSGetEnvironmentCodepage	Function	Returns the current codepage for the system Window or console.
NLSGetLocale	Subroutine	Returns the current language, country, and/or codepage.
NLSGetLocaleInfo	Function	Returns information about the current locale.
NLSSetEnvironmentCodepage	Function	Sets the codepage for the console.
NLSSetLocale	Function	Sets the current language, country, and codepage.

POSIX* Library Procedures Summary

The following table lists library procedures for POSIX*.

Programs that use POSIX procedures must access the appropriate libraries with USE IFPOSIX. The IPX *nnnn* routines are functions; the PXF *nnnn* routines are subroutines, except for the routines named PXFIS *nnnn* and PXFWIF *nnnn*.

Name	Description
IPXFARGC	Returns the index of the last command-line argument.
IPXFCONST	Returns the value associated with a constant defined in the C POSIX standard.
IPXFLENTRIM	Returns the index of the last non-blank character in an input string.
IPXFWEXITSTATUS[1]	Returns the exit code of a child process.
IPXFWSTOPSIG[1]	Returns the number of the signal that caused a child process to stop.
IPXFWTERMSIG[1]	Returns the number of the signal that caused a child process to terminate.
PXF(type)GET	Gets the value stored in a component (or field) of a structure.

Name	Description
PXF(type)SET	Sets the value of a component (or field) of a structure.
PXFA(type)GET	Gets the array values stored in a component (or field) of a structure.
PXFA(type)SET	Sets the value of an array component (or field) of a structure.
PXFACCESS	Determines the accessibility of a file.
PXFALARM	Schedules an alarm.
PXFCALLSUBHANDLE	Calls the associated subroutine.
PXFCFGETISPEED[1]	Returns the input baud rate from a `termios` structure.
PXFCFGETOSPEED[1]	Returns the output baud rate from a `termios` structure.
PXFCFSETISPEED[1]	Sets the input baud rate in a `termios` structure.
PXFCFSETOSPEED[1]	Sets the output baud rate in a `termios` structure.
PXFCHDIR	Changes the current working directory.
PXFCHMOD	Changes the ownership mode of the file.
PXFCHOWN[1]	Changes the owner and group of a file.
PXFCLEARENV	Clears the process environment.
PXFCLOSE	Closes the file associated with the descriptor.
PXFCLOSEDIR	Closes the directory stream.
PXFCNTL[1]	Manipulates an open file descriptor.
PXFCONST	Returns the value associated with a constant.
PXFCREAT	Creates a new file or rewrites an existing file.
PXFCTERMID[1]	Generates a terminal pathname.
PXFDUP, PXFDUP2	Duplicates an existing file descriptor.
PXFE(type)GET	Gets the value stored in an array element component (or field) of a structure.
PXFE(type)SET	Sets the value of an array element component (or field) of a structure.
PXFEXECV, PXFEXECVE, PXFEXECVP	Executes a new process by passing command-line arguments.
PXFEXIT, PXFFASTEXIT	Exits from a process.
PXFFDOPEN	Opens an external unit.
PXFFFLUSH	Flushes a file directly to disk.
PXFFGETC	Reads a character from a file.

Name	Description
PXFFILENO	Returns the file descriptor associated with a specified unit.
PXFFORK[1]	Creates a child process that differs from the parent process only in its PID.
PXFFPATHCONF	Gets the value for a configuration option of an opened file.
PXFFPUTC	Writes a character to a file.
PXFFSEEK	Modifies a file position.
PXFFSTAT	Gets a file's status information.
PXFFTELL	Returns the relative position in bytes from the beginning of the file.
PXFGETARG	Gets the specified command-line argument.
PXFGETC	Reads a character from standard input unit 5.
PXFGETCWD	Returns the path of the current working directory.
PXFGETEGID[1]	Gets the effective group ID of the current process.
PXFGETENV	Gets the setting of an environment variable.
PXFGETEUID[1]	Gets the effective user ID of the current process.
PXFGETGID[1]	Gets the real group ID of the current process.
PXFGETGRGID[1]	Gets group information for the specified GID.
PXFGETGRNAM[1]	Gets group information for the named group.
PXFGETGROUPS[1]	Gets supplementary group IDs.
PXFGETLOGIN	Gets the name of the user.
PXFGETPGRP[1]	Gets the process group ID of the calling process.
PXFGETPID	Gets the process ID of the calling process.
PXFGETPPID	Gets the process ID of the parent of the calling process.
PXFGETPWNAM[1]	Gets password information for a specified name.
PXFGETPWUID[1]	Gets password information for a specified UID.
PXFGETSUBHANDLE	Returns a subroutine handle for a subroutine.
PXFGETUID[1]	Gets the real user ID of the current process.
PXFISATTY[1]	Tests whether a file descriptor is connected to a terminal.
PXFISBLK	Tests for a block special file.
PXFISCHR	Tests for a character file.
PXFISCONST	Tests whether a string is a valid constant name.
PXFISDIR	Tests whether a file is a directory.

Name	Description
PXFISFIFO	Tests whether a file is a special FIFO file.
PXFISREG	Tests whether a file is a regular file.
PXFKILL	Sends a signal to a specified process.
PXFLINK[1]	Creates a link to a file or directory.
PXFLOCALTIME	Converts a given elapsed time in seconds to local time.
PXFLSEEK	Positions a file a specified distance in bytes.
PXFMKDIR	Creates a new directory.
PXFMKFIFO[1]	Creates a new FIFO.
PXFOPEN	Opens or creates a file.
PXFOPENDIR	Opens a directory and associates a stream with it.
PXFPATHCONF	Gets the value for a configuration option of an opened file.
PXFPAUSE	Suspends process execution.
PXFPIPE[1]	Creates a communications pipe between two processes.
PXFPOSIXIO[1]	Sets the current value of the POSIX I/O flag.
PXFPUTC	Outputs a character to logical unit 6 (stdout).
PXFREAD	Reads from a file.
PXFREADDIR	Reads the current directory entry.
PXFRENAME	Changes the name of a file.
PXFREWINDDIR	Resets the position of the stream to the beginning of the directory.
PXFRMDIR	Removes a directory.
PXFSETENV	Adds a new environment variable or sets the value of an environment variable.
PXFSETGID[1]	Sets the effective group ID of the current process.
PXFSETPGID[1]	Sets the process group ID.
PXFSETSID[1]	Creates a session and sets the process group ID.
PXFSETUID[1]	Sets the effective user ID of the current process.
PXFSIGACTION[1]	Changes the action associated with a specific signal.
PXFSIGADDSET[1]	Adds a signal to a signal set.
PXFSIGDELSET[1]	Deletes a signal from a signal set.
PXFSIGEMPTYSET[1]	Empties a signal set.
PXFSIGFILLSET[1]	Fills a signal set.

Name	Description
PXFSIGISMEMBER	Tests whether a signal is a member of a signal set.
PXFSIGPENDING[1]	Examines pending signals.
PXFSIGPROCMASK[1]	Changes the list of currently blocked signals.
PXFSIGSUSPEND[1]	Suspends the process until a signal is received.
PXFSLEEP	Forces the process to sleep.
PXFSTAT	Gets a file's status information.
PXFSTRUCTCOPY	Copies the contents of one structure to another.
PXFSTRUCTCREATE	Creates an instance of the specified structure.
PXFSTRUCTFREE	Deletes the instance of a structure.
PXFSYSCONF	Gets values for system limits or options.
PXFTCDRAIN[1]	Waits until all output written has been transmitted.
PXFTCFLOW[1]	Suspends the transmission or reception of data.
PXFTCFLUSH[1]	Discards terminal input data, output data, or both.
PXFTCGETATTR[1]	Reads current terminal settings.
PXFTCGETPGRP[1]	Gets the foreground process group ID associated with the terminal.
PXFTCSENDBREAK[1]	Sends a break to the terminal.
PXFTCSETATTR[1]	Writes new terminal settings.
PXFTCSETPGRP[1]	Sets the foreground process group associated with the terminal.
PXFTIME	Gets the system time.
PXFTIMES	Gets process times.
PXFTTYNAM[1]	Gets the terminal pathname.
PXFUCOMPARE	Compares two unsigned integers.
PXFUMASK	Sets a new file creation mask and gets the previous one.
PXFUNAME	Gets the operation system name.
PXFUNLINK	Removes a directory entry.
PXFUTIME	Sets file access and modification times.
PXFWAIT[1]	Waits for a child process.
PXFWAITPID[1]	Waits for a specific PID.
PXFWIFEXITED[1]	Determines if a child process has exited.
PXFWIFSIGNALED[1]	Determines if a child process has exited because of a signal.
PXFWIFSTOPPED[1]	Determines if a child process has stopped.

Name	Description
PXFWRITE	Writes to a file.

[1] This routine is only available for Linux.

Dialog Library Routines Summary

The following table lists routines from the dialog library.

Programs that use these routines must access the Dialog library with USE IFLOGM. These routines are restricted to Windows* systems.

Name	Routine Type	Description
DLGEXIT	Subroutine	Closes an open dialog.
DLGFLUSH	Subroutine	Updates the display of a dialog box.
DLGGET	Function	Retrieves values of dialog control variables.
DLGGETCHAR	Function	Retrieves values of dialog control variables of type Character.
DLGGETINT	Function	Retrieves values of dialog control variables of type Integer.
DLGGETLOG	Function	Retrieves values of dialog control variables of type Logical.
DLGINIT	Function	Initializes a dialog.
DLGINITWITHRESOURCEHANDLE	Function	Initializes a dialog.
DLGISDLGMESSAGE	Function	Determines whether a message is intended for a modeless dialog box and, if it is, processes it.
DLGISDLGMESSAGEWITHDLG	Function	Determines whether a message is intended for a specific modeless dialog box and, if it is, processes it.
DLGMODAL	Function	Displays a dialog and processes dialog selections from user.
DLGMODALWITHPARENT	Function	Displays a dialog in a specific parent window and processes dialog selections from user.
DLGMODELESS	Function	Displays a modeless dialog box.
DLGSENDCTRLMESSAGE	Function	Sends a message to a dialog box control.
DLGSET	Function	Assigns values to dialog control variables.
DLGSETCHAR	Function	Assigns values to dialog control variables of type Character.

Name	Routine Type	Description
DLGSETCTRLEVENTHANDLER	Function	Assigns your own event handlers to ActiveX controls in a dialog box.
DLGSETINT	Function	Assigns values to dialog control variables of type Integer.
DLGSETLOG	Function	Assigns values to dialog control variables of type Logical.
DLGSETRETURN	Subroutine	Sets the return value for DLGMODAL.
DLGSETSUB	Function	Assigns procedures (callback routines) to dialog controls.
DLGSETTITLE	Subroutine	Sets the title of a dialog box.
DLGUNINIT	Subroutine	Deallocates memory occupied by an initialized dialog.

COM and Automation Library Routines

The COM and Automation routines are restricted to Windows* systems.

The following tables list COM and Automation libary routines.

Programs that use COM routines must access the appropriate libraries with USE IFCOM. Programs that use automation routines must access the appropriate libraries with USE IFAUTO. Some procedures also require the USE IFWINTY module.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

Component Object Model (COM) Procedures (USE IFCOM)

Name	Routine Type	Description
COMAddObjectReference	Function	Adds a reference to an object's interface.
COMCLSIDFromProgID[1]	Subroutine	Passes a programmatic identifier and returns the corresponding class identifier.
COMCLSIDFromString[1]	Subroutine	Passes a class identifier string and returns the corresponding class identifier.
COMCreateObject[1]	Subroutine	A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.
COMCreateObjectByGUID[1]	Subroutine	Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.

Name	Routine Type	Description
COMCreateObjectByProgID	Subroutine	Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object's IDispatch interface.
COMGetActiveObjectByGUID[1]	Subroutine	Passes a class identifier and returns a pointer to the interface of a currently active object.
COMGetActiveObjectByProgID	Subroutine	Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.
COMGetFileObject	Subroutine	Passes a file name and returns a pointer to the IDispatch interface of an Automation object that can manipulate the file.
COMInitialize	Subroutine	Initializes the COM library.
COMIsEqualGUID[1]	Function	Determines whether two GUIDs are the same.
COMQueryInterface[1]	Subroutine	Passes an interface identifier and returns a pointer to an object's interface.
COMReleaseObject	Function	Indicates that the program is done with a reference to an object's interface.
COMStringFromGUID[1]	Subroutine	Passes a GUID and returns a string of printable characters.
COMUninitialize	Subroutine	Uninitializes the COM library.

Automation Server Procedures (USE IFAUTO)

Name	Routine Type	Description
AUTOAddArg[1]	Subroutine	Passes an argument name and value and adds the argument to the argument list data structure.
AUTOAllocateInvokeArgs	Function	Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.
AUTODeallocateInvokeArgs	Subroutine	Deallocates an argument list data structure.
AUTOGetExceptInfo	Subroutine	Retrieves the exception information when a method has returned an exception status.
AUTOGetProperty[1]	Function	Passes the name or identifier of the property and gets the value of the Automation object's property.

Name	Routine Type	Description
AUTOGetPropertyByID	Function	Passes the member ID of the property and gets the value of the Automation object's property into the argument list's first argument.
AUTOGetPropertyInvokeArgs	Function	Passes an argument list data structure and gets the value of the Automation object's property specified in the argument list's first argument.
AUTOInvoke	Function	Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments.
AUTOSetProperty[1]	Function	Passes the name or identifier of the property and a value, and sets the value of the Automation object's property.
AUTOSetPropertyByID	Function	Passes the member ID of the property and sets the value of the Automation object's property, using the argument list's first argument.
AUTOSetPropertyInvokeArgs	Function	Passes an argument list data structure and sets the value of the Automation object's property specified in the argument list's first argument.

[1]These routines also require USE IFWINTY.

Miscellaneous Runtime Library Routines

The following table lists miscellaneous runtime library routines.

Programs that use most of these routines should contain a USE IFCORE statement to obtain the proper interfaces to these routines.

Name	Procedure Type	Description
COMMITQQ	Function	Forces the operating system to execute any pending write operations for a file.
FOR_DESCRIPTOR_ASSIGN[1]	Subroutine	Creates an array descriptor in memory.
FOR_GET_FPE	Function	Returns the current settings of floating-point exception flags.
FOR_LFENCE	Subroutine	Inserts a memory load fence instruction that ensures completion of preceding load instructions.

Name	Procedure Type	Description
FOR_MFENCE	Subroutine	Inserts a memory access fence instruction that ensures completion of preceding memory access instructions.
for_rtl_finish_[2]	Function	Cleans up the Fortran runtime environment.
for_rtl_init_[2]	Function	Initializes the Fortran runtime environment.
FOR_SET_FPE	Function	Sets the floating-point exception flags.
FOR_SET_FTN_ALLOC	Function	Tells the Fortran Runtime Library (RTL) to use a user-defined routine to dynamically allocate commons.
FOR_SET_REENTRANCY	Function	Controls the type of reentrancy protection that the Fortran Runtime Library (RTL) exhibits.
FOR_SFENCE	Subroutine	Inserts a memory store fence instruction that ensures completion of preceding store instructions.
GERROR	Subroutine	Returns a message for the last error detected by a Fortran runtime routine.
GETCHARQQ	Function	Returns the next keystroke.
GETEXCEPTIONPTRSQQ[1]	Function	Returns a pointer to C runtime exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.
GETSTRQQ	Function	Reads a character string from the keyboard using buffered input.
PEEKCHARQQ	Function	Checks the buffer to see if a keystroke is waiting.
PERROR	Subroutine	Sends a message to the standard error stream, preceded by a specified string, for the last detected error.
TRACEBACKQQ	Subroutine	Provides traceback information.

[1] Windows

[2] You do not need a USE IFCORE statement for this routine.

A to B

This section describes language features that start with A or B.

A to B

ABORT

Portability Subroutine: *Flushes and closes I/O buffers, and terminates program execution.*

Module

USE IFPORT

Syntax

`CALL ABORT[string]`

string	(Input; optional) Character*(*). Allows you to specify an abort message at program termination. When ABORT is called, "abort:" is written to external unit 0, followed by *string*. If omitted, the default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the program that launched it.

Example

```
USE IFPORT
!The following prints "abort: Fortran Abort Called"
CALL ABORT
!The following prints "abort: Out of here!"
Call ABORT ("Out of here!")
```

See Also

EXIT

STOP

ABS

Elemental Intrinsic Function (Generic): *Computes an absolute value.*

Syntax

`result=ABS(a)`

a	(Input) Must be of type integer, real, or complex.

Results

The result has the same type and kind type parameter as *a* except if *a* is complex value, the result type is real. If *a* is an integer or real value, the value of the result is | *a* |; if *a* is a complex value (X, Y), the result is the real value SQRT (X**2 + Y**2).

Specific Name	Argument Type	Result Type
BABS	INTEGER(1)	INTEGER(1)
IIABS[1]	INTEGER(2)	INTEGER(2)
IABS [2]	INTEGER(4)	INTEGER(4)
KIABS	INTEGER(8)	INTEGER(8)
ABS	REAL(4)	REAL(4)

Specific Name	Argument Type	Result Type
DABS	REAL(8)	REAL(8)
QABS	REAL(16)	REAL(16)
CABS [3]	COMPLEX(4)	REAL(4)
CDABS[4]	COMPLEX(8)	REAL(8)
CQABS	COMPLEX(16)	REAL(16)

[1]Or HABS.

[2]Or JIABS. For compatibility with older versions of Fortran, IABS can also be specified as a generic function, which allows integer arguments of any kind and produces a result of type default INTEGER.

[3]The setting of compiler options specifying real size can affect CABS, making CABS generic, which allows a complex argument of any kind to produce a result of default REAL.

[4]This function can also be specified as ZABS.

Example

ABS (-7.4) has the value 7.4.

ABS ((6.0, 8.0)) has the value 10.0.

The following ABS.F90 program calculates two square roots, retaining the sign:

```
        REAL mag(2), sgn(2), result(2)
        WRITE (*, '(A)') ' Enter two signed magnitudes: '
        READ (*, *) mag
        sgn = SIGN((/1.0, 1.0/), mag) ! transfer the signs to 1.0s
        result = SQRT (ABS (mag))
! Restore the sign by multiplying by -1 or +1:
        result = result * sgn
        WRITE (*, *) result
        END
```

ABSTRACT INTERFACE

Statement: *Defines an abstract interface.*

Syntax

```
ABSTRACT INTERFACE
   [interface-body]...
END INTERFACE
```

interface-body

Is one or more function or subroutine subprograms or a procedure pointer.

The interface body must *not* contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

The subprogram can contain a USE statement to import entities and types defined in a module.

The subprogram can contain in IMPORT statement to make entities from the interfaces host scoping unit accessible to the interface body.

Executable code and specification statements that are not used to specify characteristics of the subprogram or its dummy arguments in an interface body are ignored.

Description

An abstract interface block defines an interface whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics or to define interfaces of type bound procedures.

An abstract interface block cannot contain a PROCEDURE statement or a MODULE PROCEDURE statement.

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association unless an IMPORT statement appears in the interface block .

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

Example

Previously, within an interface block, you needed to individually declare subroutines and functions that had the same argument keywords and characteristics. For example:

```
INTERFACE
SUBROUTINE SUB_ONE (X)
  REAL, INTENT(IN) :: X
END SUBROUTINE SUB_ONE
SUBROUTINE SUB_TWO (X)
  REAL, INTENT(IN) :: X
END SUBROUTINE SUB_TWO
...
END INTERFACE
```

Now you can use an abstract interface to specify a subprogram name for these identical arguments and characteristics. For example:

```
ABSTRACT INTERFACE
SUBROUTINE MY_INTERFACE (X)
  REAL, INTENT(IN) :: X
END SUBROUTINE MY_INTERFACE
END INTERFACE
```

You can then use the subprogram in the abstract interface as a template in a PROCEDURE statement to declare procedures. For example:

```
PROCEDURE (MY_INTERFACE) :: SUB_ONE, SUB_TWO, ...
```

SUBROUTINE
Procedure Interfaces
Use and Host Association

ACCEPT

Statement: *Transfers input data.*

Syntax

Formatted:

```
ACCEPT form[,io-list]
```

Formatted - List-Directed:

```
ACCEPT *[,io-list]
```

Formatted - Namelist:

```
ACCEPT nml
```

form	Is the nonkeyword form of a format specifier (no FMT=).
io-list	Is an I/O list.
*	Is the format specifier indicating list-directed formatting.
nml	Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

The ACCEPT statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using environment variable FOR_ACCEPT.

Example

In the following example, character data is read from the implicit unit and binary values are assigned to each of the five elements of array CHARAR:

```
     CHARACTER*10 CHARAR(5)
     ACCEPT 200, CHARAR
200  FORMAT (5A10)
```

ACCESS Function

Portability Function: *Determines if a file exists and how it can be accessed.*

Module

USE IFPORT

Syntax

```
result = ACCESS(name,mode)
```

name	(Input) Character*(*). Name of the file whose accessibility is to be determined.
mode	(Input) Character*(*). Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

Character	Meaning
r	Tests for read permission
w	Tests for write permission

Character	Meaning
x	Tests for execute permission. On Windows* systems, the extension of *name* must be .COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.
(blank)	Tests for existence

The characters within *mode* can appear in any order or combination. For example, wrx and r are legal forms of *mode* and represent the same set of inquiries.

Results

The value of the result is INTEGER(4). It is zero if all inquiries specified by *mode* are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:

- EACCES: Access denied; the file's permission setting does not allow the specified access
- EINVAL: The mode argument is invalid
- ENOENT: File or path not found

For a list of error codes, see IERRNO.

The *name* argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

Example

```
use ifport
! checks for read and write permission on the file "DATAFILE.TXT"
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J
! checks whether "DATAFILE.TXT" is executable. It is not, since
! it does not end in .COM, .EXE, .BAT, or .CMD
J = ACCESS ("DATAFILE.TXT","x")
PRINT *, J
```

GETFILEINFOQQ

ACHAR

Elemental Intrinsic Function (Generic): *Returns the character in a specified position of the ASCII character set, even if the processor's default character set is different. It is the inverse of the IACHAR function. In Intel® Fortran, ACHAR is equivalent to the CHAR function.*

Syntax

`result = ACHAR (i [, kind])`

i	(Input) Is of type integer.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is character with length 1. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *i* has a value within the range 0 to 127, the result is the character in position *i* of the ASCII character set; otherwise, it is processor defined. ACHAR (IACHAR(C)) has the value C for any character C capable of representation in the default character set. For a complete list of ASCII character codes, see Character and Key Code Charts.

Example

ACHAR (71) has the value 'G'.

ACHAR (63) has the value '?'.

CHAR
IACHAR
ICHAR

ACOS

Elemental Intrinsic Function (Generic): *Produces the arccosine of x in radians.*

Syntax

```
result = ACOS (x)
```

x	(Input) Must be of type real, where | *x* | must be less than or equal to 1, or of type complex.

Results

The result type and kind are the same as *x* and is expressed in radians.

If the result is real, the value is expressed in radians and lies in the range 0 <= ACOS(X) <= pi.

If the result is complex, the real part is expressed in radians and lies in the range 0 <= REAL(ACOS (x)) <= pi.

Specific Name	Argument Type	Result Type
ACOS [1]	REAL(4)	REAL(4)
DACOS [1]	REAL(8)	REAL(8)
QACOS [2]	REAL(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect ACOS and DACOS.

[2]Or QARCOS.

Example

ACOS (0.68032123) has the value .8225955.

ACOSD

Elemental Intrinsic Function (Generic): *Produces the arccosine of x in degrees.*

Syntax

```
result = ACOSD (x)
```

x (Input) Must be of type real. The | *x* | must be less than or equal to 1.

Results

The result type and kind are the same as *x* and are expressed in degrees. The value lies in the range −90 to 90 degrees.

Specific Name	Argument Type	Result Type
ACOSD [1]	REAL(4)	REAL(4)
DACOSD [1]	REAL(8)	REAL(8)
QACOSD	REAL(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect ACOSD and DACOSD.

Example

ACOSD (0.886579) has the value 27.55354.

ACOSH

Elemental Intrinsic Function (Generic): *Produces the hyperbolic arccosine of x.*

Syntax

```
result = ACOSH (x)
```

x (Input) Must be of type real, where *x* must be greater than or equal to 1, or of type complex.

Results

The result type and kind are the same as *x*.

If the result is complex, the real part is non-negative, and the imaginary part is expressed in radians and lies in the range -pi <= AIMAG (ACOSH (x)) <= pi.

Specific Name	Argument Type	Result Type
ACOSH [1]	REAL(4)	REAL(4)
DACOSH [1]	REAL(8)	REAL(8)
QACOSH	REAL(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect ACOSH and DACOSH.

Example

ACOSH (1.0) has the value 0.0.

ACOSH (180.0) has the value 5.8861.

ADJUSTL

Elemental Intrinsic Function (Generic): *Adjusts a character string to the left, removing leading blanks and inserting trailing blanks.*

Syntax

```
result = ADJUSTL (string)
```

string (Input) Must be of type character.

Results

The result type is character with the same length and kind parameter as *string*. The value of the result is the same as *string*, except that any leading blanks have been removed and inserted as trailing blanks.

Example

```
CHARACTER(16) STRING
STRING= ADJUSTL('   Fortran 90   ') ! returns 'Fortran 90      '

ADJUSTL ('    SUMMERTIME')     ! has the value 'SUMMERTIME    '
```

See Also

ADJUSTR

ADJUSTR

Elemental Intrinsic Function (Generic): *Adjusts a character string to the right, removing trailing blanks and inserting leading blanks.*

Syntax

```
result = ADJUSTR (string)
```

string (Input) Must be of type character.

Results

The result type is character with the same length and kind parameter as *string*.

The value of the result is the same as *string*, except that any trailing blanks have been removed and inserted as leading blanks.

Example

```
CHARACTER(16) STRING
STRING= ADJUSTR('   Fortran 90   ') ! returns '     Fortran 90'

ADJUSTR ('SUMMERTIME    ')     ! has the value '    SUMMERTIME'
```

See Also

ADJUSTL

AIMAG

Elemental Intrinsic Function (Generic): *Returns the imaginary part of a complex number. This function can also be specified as IMAG.*

Syntax

```
result = AIMAG (z)
```

z (Input) Must be of type complex.

Results

The result type is real with the same kind parameter as *z*. If *z* has the value (x, y), the result has the value y.

Specific Name	Argument Type	Result Type
AIMAG [1]	COMPLEX(4)	REAL(4)
DIMAG	COMPLEX(8)	REAL(8)
QIMAG	COMPLEX(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect AIMAG.

To return the real part of complex numbers, use REAL.

Example

AIMAG ((4.0, 5.0)) has the value 5.0.

If C is complex, C%IM is the same as AIMAG (C).

The program AIMAG.F90 applies the quadratic formula to a polynomial and allows for complex results:

```
REAL a, b, c
COMPLEX ans1, ans2, d
WRITE ( *, 100)
100 FORMAT ('  Enter A, b, and c of the  ',   &
                          'polynomial ax**2 + bx + c:  '\)
READ (*, *) a, b, c
d = CSQRT (CMPLX (b**2 - 4.0*a*c))  ! d is either:
                                    !  0.0 + i root, or
                                    !  root + i 0.0
ans1 = (-b + d) / (2.0 * a)
ans2 = (-b + d) / (2.0 * a)
WRITE (*, 200)
200 FORMAT (/ '  The roots are:'  /)
WRITE (*, 300) REAL(ans1), AIMAG(ans1), &
                  REAL(ans2), AIMAG(ans2)
300 FORMAT (' X = ', F10.5, ' + i', F10.5)
END
```

See Also

CONJG
DBLE

AINT

Elemental Intrinsic Function (Generic): *Truncates a value to a whole number.*

Syntax

```
result = AINT (a [,kind])
```

a (Input) Must be of type real.

kind (Input; optional) Must be a scalar integer constant expression.

Results

The result type is real. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter is that of *a*.

The result is defined as the largest integer whose magnitude does not exceed the magnitude of *a* and whose sign is the same as that of *a*. If | *a* | is less than 1, AINT(*a*) has the value zero.

Specific Name	Argument Type	Result Type
AINT [1]	REAL(4)	REAL(4)
DINT [1]	REAL(8)	REAL(8)
QINT	REAL(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect AINT and DINT.

To round rather than truncate, use ANINT.

Example

AINT (3.678) has the value 3.0.

AINT (-1.375) has the value -1.0.

```
REAL r1, r2
REAL(8) r3(2)
r1 = AINT(2.6)    ! returns the value 2.0
r2 = AINT(-2.6)   ! returns the value -2.0
r3 = AINT((/1.3, 1.9/), KIND = 8)       ! returns the values
                                        ! (1.0D0, 1.0D0)
```

See Also

ANINT

ALARM

Portability Function: *Causes a subroutine to begin execution after a specified amount of time has elapsed.*

Module

USE IFPORT

Syntax

`result = ALARM (time,proc)`

time (Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when *proc* is to begin execution. If *time* is 0, the alarm is turned off and no routine is called.

proc (Input) Name of the procedure to call. The procedure takes no arguments and must be declared EXTERNAL.

Results

The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After ALARM is called and the timer starts, the calling program continues for *time* seconds. The calling program then suspends and calls *proc*, which runs in another thread. When *proc* finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If *proc* performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries.

The thread that *proc* runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until *proc* terminates, or is blocked on some other event, such as I/O.

No alarms can occur after the main process ends. If the main program finishes or any thread executes an EXIT call, than any pending alarm is deactivated before it has a chance to run.

Example

```
USE IFPORT
INTEGER(4) numsec, istat
EXTERNAL subprog
numsec = 4
write *, "subprog will begin in ", numsec, " seconds"
ISTAT = ALARM (numsec, subprog)
```

See Also

RUNQQ

ALIAS Directive

General Compiler Directive: *Declares alternate external names for external subprograms.*

Syntax

```
!DIR$ ALIAS internal-name,external-name
```

internal-name	The name of the entity as used in the current program unit. It can be a procedure name, a COMMON block name, a module variable that is initialized, or a PARAMETER in a module. It may not be the name of an internal procedure.
external-name	A name or a character constant, delimited by apostrophes or quotation marks.

If a name is specified, the name (in uppercase) is used as the external name for the specified *internal-name.* If a character constant is specified, it is used as is; the string is not changed to uppercase, nor are blanks removed.

The ALIAS directive affects only the external name used for references to the specified *internal-name.*

Names that are not acceptable to the linker will cause link-time errors.

See Also

ATTRIBUTES ALIAS
ATTRIBUTES DECORATE
ATTRIBUTES DEFAULT
General Compiler Directives

Syntax Rules for Compiler Directives

ALIGNED Clause

Parallel Directive Clause: *Specifies that all variables in a list are aligned.*

Syntax

```
ALIGNED (list [:n])
```

list	Is the name of one or more variables. Each name must be separated by a comma. Any variable that appears in *list* cannot appear in more than one ALIGNED clause.
n	Must be a constant positive integer expression; it indicates the number of bytes for the alignment. If *n* is not specified, the compiler uses the default alignment specified for SIMD instructions on the target platform.

The ALIGNED clause declares that the location of each list item is aligned to the number of bytes expressed in the optional alignment parameter *n* of the ALIGNED clause. If a list item has the ALLOCATABLE attribute, its allocation status must be allocated. If it has the POINTER attribute, its association status must be associated. If the type of a list item is type(C_PTR) or a Cray pointer, the item must be defined.

NOTE
Be careful when using the ALIGNED clause. Instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

ALL

Transformational Intrinsic Function (Generic): *Determines if all values are true in an entire array or in a specified dimension of an array.*

Syntax

```
result = ALL (mask)
result = ALL (mask, dim)
```

mask	(Input) Must be a logical array.
dim	(Input) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *mask*.

Results

The result is an array or a scalar of type logical.

The result is a scalar if *dim* is not specified or *mask* has rank one. A scalar result is true only if all elements of *mask* are true, or *mask* has size zero. The result has the value false if any element of *mask* is false.

An array result has the same type and kind parameters as *mask*, and a rank that is one less than *mask*. Its shape is (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2,..., d_n) is the shape of *mask*.

Each element in an array result is true only if all elements in the one dimensional array defined by *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) are true.

Example

```
       LOGICAL mask( 2, 3), AR1(3), AR2(2)
       mask = RESHAPE((/.TRUE., .TRUE., .FALSE., .TRUE., .FALSE., &
                       .FALSE./),(/2,3/))
! mask is true false false
! true true false
      AR1 = ALL(mask,DIM = 1) ! evaluates the elements column by
               ! column yielding [true false false]
      AR2 = ALL(mask,DIM = 2) ! evaluates the elements row by row
               ! yielding [false false].
```

ALL ((/.TRUE., .FALSE., .TRUE./)) has the value false because some elements of MASK are not true.

ALL ((/.TRUE., .TRUE., .TRUE./)) has the value true because *all* elements of MASK are true.

A is the array

```
   [ 1  5  7 ]
   [ 3  6  8 ]
```

and B is the array

```
   [ 0  5  7 ]
   [ 2  6  9 ].
```

ALL (A .EQ. B, DIM=1) tests to see if all elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, false) because only the second column has elements that are all equal.

ALL (A .EQ. B, DIM=2) tests to see if all elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (false, false) because each row has some elements that are not equal.

ANY
COUNT

ALLOCATABLE

Statement and Attribute: *Specifies that an object is allocatable. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array. A character object may have a deferred length that is determined when the object is allocated with an ALLOCATE statement. A allocatable scalar object of any type may be allocated with an ALLOCATE statement.*

Syntax

The ALLOCATABLE attribute can be specified in a type declaration statement or an ALLOCATABLE statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] ALLOCATABLE [, *att-ls*] :: *a*[(*d-spec*)] [[*coarray-spec*]][, *a*[(*d-spec*)] [[*coarray-spec*]]...

Statement:

ALLOCATABLE [::] *a*[(*d-spec*)] [[*coarray-spec*]][, *a*[(*d-spec*)] [[*coarray-spec*]]...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
a	Is the name of the allocatable object.
d-spec	Is a deferred-shape specification (: [, :] ...), where each colon represents a dimension of the array or a deferred-coshape specification.
coarray-spec	Is a deferred-coshape specification. The left bracket and right bracket are required.

Description

A character object declaration uses LEN=: to indicate it is deferred length.

If the array is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

When the allocatable object is no longer needed, it can be deallocated by execution of a DEALLOCATE statement.

An allocatable object cannot be specified in a COMMON, EQUIVALENCE, DATA, or NAMELIST statement.

Allocatable objects are not saved by default. If you want to retain the values of an allocatable object across procedure calls, you must specify the SAVE attribute for the object.

Example

```
! Method for declaring and allocating objects.

INTEGER, ALLOCATABLE :: matrix(:,:)        ! deferred shape
REAL, ALLOCATABLE    :: vector(:)
CHARACTER, ALLOCATABLE :: c1               ! char scalar, len=1
INTEGER, ALLOCATABLE :: k                  ! numeric scalar
CHARACTER(LEN=:), ALLOCATABLE :: c2, c3(:) ! deferred length, shape

ALLOCATE(matrix(3,5),vector(-2:N+2))       ! specifies shapes
ALLOCATE(c1)                               ! specifies scalar, len=1
ALLOCATE(k)                                ! specifies scalar
ALLOCATE(character(len=5) :: c2)           ! specifies scalar, len=5
ALLOCATE(character(len=3) :: c3(2:4))      ! specifies length, shape
```

The following example shows a type declaration statement specifying the ALLOCATABLE attribute:

```
REAL, ALLOCATABLE :: Z(:, :, :)
```

The following is an example of the ALLOCATABLE statement:

```
REAL A, B(:)
ALLOCATABLE :: A(:,:), B
```

ALLOCATE Clause

Parallel Directive Clause: *Specifies the memory allocator to be used for one or more private variables or common blocks of a construct. This feature is only available for ifx.*

Syntax

```
ALLOCATE ([allocator :] list)
```

-or-

```
ALLOCATE (allocator-modifier [, allocator-modifier] : list)
```

allocator

Is an integer expression with a kind type of omp_allocator_handle_kind.

list

Is a comma-separated list of variables or named common blocks that have been specified in a data sharing clause on the same directive that makes the variable or common block private for the construct. A common block name must be enclosed in slashes (/ /). A list item cannot be repeated in the list.

allocate-modifier

Is one of the following:

- ALLOCATOR (*allocator*)

  allocator is an integer expression with a kind type of `omp_allocator_handle_kind`.

  At most one ALLOCATOR *allocate-modifier* is permitted in the ALLOCATE clause.
- ALIGN (*alignment*)

  alignment is a positive integer scalar expression with a value that is a positive power of two.

  Each *list* item is allocated with a byte alignment of at least the maximum of the following:

  1.The required alignment specified by Fortran
  2.The alignment trait of the specified *allocator*
  3.The *alignment* value specified by the ALIGN *allocate-modifier*

  If *alignment* is not specified, each *list* item is allocated with a byte alignment of at least the maximum of the following:

  1.The required alignment specified by Fortran
  2.The alignment trait of the specified *allocator*

  At most one ALIGN *allocate-modifier* is permitted in the ALLOCATE clause.

If *allocator* is not specified, the list items in the clause will be allocated using the allocator specified by the `def-allocator-var` internal control variable (ICV).

Each *list* item must appear in a data sharing clause that creates a private copy of the *list* item in the directive containing the ALLOCATE clause. The storage for the private copies of an object specified in the *list* are allocated using the specified memory allocator.

An ALLOCATE clause in a TARGET directive or a directive within a TARGET region must specify an *allocator* expression unless a REQUIRES directive with the DYNAMIC_ALLOCATORS clause appears in the same compilation unit.

The result of allocating private variables with a memory allocator whose access trait is set to THREAD by a TASK, TASKLOOP, or TARGET directive is undefined.

ALLOCATE Directive
OpenMP* Memory Spaces and Allocators

ALLOCATE Directive

OpenMP* Fortran Compiler Directive: *Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.*

Syntax

```
!$OMP ALLOCATE (list) [clause [[,] clause]...]
```

-or-

```
!$OMP ALLOCATE [(list)] [clause [[,] clause]...]
[!$OMP ALLOCATE (list) [clause [[,] clause]...]
[...]]
ALLOCATE statement
```

list

Is a comma separated list of variables or named common blocks. A common block name must be enclosed in slashes (/ /).

clause

Is one of the following:

- ALIGN (*alignment*)

  alignment is a positive integer scalar expression with a value that is a positive power of two.

  Each *list* item is allocated with a byte alignment of at least the maximum of the following:

  1.The required alignment specified by Fortran
  2.The alignment trait of the specified *allocator*
  3.The *alignment* value specified by the ALIGN clause

  If the ALIGN clause is not specified, each *list* item is allocated with a byte alignment of at least the maximum of the following:

  1.The required alignment specified by Fortran
  2.The alignment trait of the specified *allocator*

  At most one ALIGN clause is permitted in the ALLOCATE directive.
- ALLOCATOR (*allocator*)

  allocator is an integer expression with a kind type of `omp_allocator_handle_kind`.

  If the ALLOCATOR clause is not specified, the *list* items in that directive will be allocated using the allocator specified by the `def-allocator-var` internal control variable (ICV).

At most one ALLOCATOR clause is permitted in the ALLOCATE directive.

The first form of the directive is not associated with an ALLOCATE statement. It is a declarative directive and must appear in the specification part where the *list* items are declared, and after all declarations of the *list* items. The storage for each *list* item will be allocated by the specified memory allocator and deallocated by the same memory allocator when the list item goes out of scope.

The *list* items in a declarative ALLOCATE directive must not have the POINTER or ALLOCATABLE attribute. If a *list* item has the SAVE attribute (implicitly or explicitly), is a common block name, or is declared in the scope of a module or submodule, then the specified *allocator* must be one of the pre-defined memory allocators. The *list* items in a declarative ALLOCATE directive cannot be an array element, a structure component, or a variable in a common block. The declaration of all *list* items must be in the same scope as the declarative ALLOCATE directive and must precede the ALLOCATE directive.

A *list* item can appear once in a declarative ALLOCATE directive and it can appear in only one declarative ALLOCATE directive.

The second form of the ALLOCATE directive is associated with an ALLOCATE statement and can appear in the executable statement part of a subprogram after the first executable statement or OpenMP* construct. This form of the directive has been deprecated in OpenMP 5.2 and replaced by the ALLOCATORS construct. It associates an *allocator* with each allocate item in the associated ALLOCATE statement. The following are other rules for this form:

- If an ALLOCATE directive with no *list* items appears, all the allocate list objects in the ALLOCATE statement that are not listed in an ALLOCATE directive associated with the same ALLOCATE statement, are allocated by the *allocator* specified in the ALLOCATE directive with no list items specified.
- Multiple ALLOCATE directives with *list* items can be specified for an ALLOCATE statement.
- An allocate object in an ALLOCATE statement associated with an ALLOCATE directive can be associated with only one allocator, either explicitly (as a list item) or implicitly (if no list appears in an ALLOCATE directive) for that ALLOCATE statement.

A *list* item can not appear in more than one ALLOCATE directive associated with a given ALLOCATE statement, or appear more than once in the same directive. Each *list* item must have the ALLOCATABLE or POINTER attribute; therefore, it cannot be a common block name enclosed in slashes. A *list* item can be a POINTER or ALLOCATABLE component of a derived type. A *list* item cannot be an associate name.

If an object appears as a *list* item of an ALLOCATE directive, it must also appear in the allocation list of the associated ALLOCATE statement. When an object is deallocated, it is deallocated using the same allocator used to allocate it. If an object is deallocated and reallocated during intrinsic assignment, the same allocator is used for the deallocation and reallocation; otherwise, the *allocator* specified for a *list* item is used to allocate the *list* item only in the ALLOCATE statement associated with the ALLOCATE directive.

If an allocate object in an ALLOCATE statement associated with an OpenMP ALLOCATE directive does not appear as a list item in the directive, the allocate object is ALLOCATED as if it appeared in a Fortran ALLOCATE statement that was not associated with an OpenMP ALLOCATE directive.

If multiple ALLOCATE directives are associated with an ALLOCATE statement, only one ALLOCATE directive can appear with no *list* items.

An ALLOCATOR must be specified in ALLOCATE directives that appear in a TARGET region, unless a REQUIRES directive with the DYNAMIC_ALLOCATORS clause is specified in the same compilation unit.

When a *list* item goes out of scope, if it has not been deallocated, it is automatically deallocated with the same *allocator* that allocated it.

OpenMP* Memory Spaces and Allocators

ALLOCATE Statement

Statement: *Dynamically creates storage for allocatable variables and pointer targets.*

Syntax

```
ALLOCATE ([type::] object[(s-spec[, s-spec]...)] [, object[(s-spec[, s-spec]...)] ]...
[[coarray-spec]]...[, alloc-opt[, alloc-opt]...])
```

type

Is a data type specifier. If specified, the kind type parameters of each *object* must be the same as the corresponding *type* parameter values, and each object must be type compatible with the specified type. The type must not have an ultimate subcomponent that is a coarray.

You cannot specify *type* if you specify SOURCE= or MOLD=.

A type parameter value in *type* can be an asterisk if and only if each *object* is a dummy argument for which the corresponding type parameter is assumed.

object

Is the object to be allocated. It is a variable name or structure component, and must be a pointer or an allocatable object. The object can be of type character with zero length. The object cannot be coindexed.

If any object has a deferred type parameter, is unlimited polymorphic, or is of ABSTRACT type, either *type* or *source-expr* must appear.

If the object is a coarray and *type* is specified, *type* cannot be C_PTR, C_FUNPTR, or TEAM_TYPE.

If the object is a coarray and SOURCE= is specified, the declared type of *source-expr* cannot be C_PTR, C_FUNPTR, or TEAM_TYPE.

If *object* is an array, *s-spec* must appear and the number of *s-specs* must equal the rank of *object*, or *source-expr* must appear and have the same rank as *object* and the shape of *object* is that of *source-expr*.

If both *s-spec* and SOURCE=*source-expr* appear, *source-expr* must be scalar.

If *object* is scalar, no *s-spec* should appear.

If SOURCE=*source-expr* appears, *object* is initialized with the value of *source-expr*.

s-spec

Is an array shape specification in the form [lower-bound:]upper-bound. Each bound must be a scalar integer expression. The number of shape specifications must be the same as the rank of the *object*.

You can specify an *s-spec* list for each array object in an ALLOCATE statement.

coarray-spec

Is a coarray shape specification in the form:

[[lower-bound:] upper-bound,] ... [lower-bound:] *

The brackets around coarray-spec are required.

A coarray shape specification can only appear if the object is a coarray. The number of coarray specifications must be one less than the corank of the coarray object.

alloc-opt

Can be any of the following keywords:

STAT=*stat-var*

(Output) The *stat-var* is a scalar integer variable in which the status of the allocation is stored.

If no STAT= *stat-var* is specified and an error condition occurs, the program initiates error termination.

ERRMSG=*err-var*

(Output) The *err-var* is a scalar default character variable in which an error condition is stored if such a condition occurs.

SOURCE=*source-expr*
MOLD=*source-expr*

(Input) The *source-expr* is an expression that is scalar or has the same rank as *object*.

If MOLD= or SOURCE= is specified, *type* cannot be specified and each object must have the same rank as *source-expr* unless *source-expr* is scalar.

Only one of MOLD= or SOURCE= can appear in the same ALLOCATE statement.

If MOLD= appears and *source-expr* is a variable, its value does not have to be defined.

If *source-expr* appears and its declared type is C_PTR or C_FUNPTR, *object* cannot be a coarray.

If *object* is a coarray:

- The declared type of *source-expr* cannot be EVENT_TYPE, LOCK_TYPE, or TEAM_TYPE or have a subcomponent of these types.
- *source-expr* must not have a dynamic type of C_PTR, C_FUNPTR, EVENT_TYPE, or LOCK_TYPE, or have a subcomponent whose dynamic type is EVENT_TYPE or LOCK_TYPE.

You can specify STAT=, ERRMSG=, and one of MOLD= or SOURCE= in the same ALLOCATE statement. The keywords can appear in any order.

Description

The storage space allocated is uninitialized unless SOURCE= is specified or the type of the object is default initialized.

A bound in *s-spec* must not be an expression containing an array inquiry function whose argument is any allocatable object in the same ALLOCATE statement; for example, in this code, the last line is not permitted:

```
INTEGER ERR
INTEGER, ALLOCATABLE :: A(:), B(:)
...
ALLOCATE(A(10:25), B(SIZE(A)), STAT=ERR)  ! A is invalid as an argument to function SIZE
```

If a STAT=stat-var, ERRMSG=err-var, or *source-expr* is specified, it must not be allocated in the ALLOCATE statement in which it appears; nor can it depend on the value, bounds, length type parameters, allocation status, or association status of any object in the same ALLOCATE statement.

If the allocation is successful, the STAT=stat-var becomes defined with the value zero, and the definition status of the ERRMSG=err-var remains unchanged. If the allocation is not successful, an error condition occurs, and the STAT=stat-var is set to a positive integer value (representing the runtime error); the ERRMSG=err-var contains a descriptive message about the error condition.

If the allocation is successful and *source-expr* is specified, the dynamic type and value of the allocated object becomes that of the source expression. If the value of a non-deferred length type parameter of *object* is different from the value of the corresponding type parameter of *source-expr*, an error condition occurs.

When an ALLOCATE statement is executed for an *object* that is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the same statement the same number of times.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has initiated normal termination, the STAT=stat-var becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. Otherwise, if an allocatable object is a coarray and one or more images of the current team has failed, the STAT=stat-var becomes defined with the processor-dependent positive integer value of the constant STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT=stat-var becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has failed, each allocatable object is successfully allocated or deallocated on the active images of the current team. If any other error occurs, the allocation status of each allocatable object is processor dependent:

- Successfully allocated allocatable objects have the allocation status of allocated, or associated if the allocate object is has the POINTER attribute.
- Successfully deallocated allocatable objects have the allocation status of deallocated, or disassociated if the allocatable object has the POINTER attribute.
- An allocatable object that was not successfully allocated or deallocated has its previous allocation status, or its previous association status if it has the POINTER attribute.

To release the storage for an object, use DEALLOCATE.

To determine whether an allocatable object is currently allocated, use the ALLOCATED intrinsic function.

To determine whether a pointer is currently associated with a target, use the ASSOCIATED intrinsic function.

Example

The following example shows a method for creating and allocating deferred shape arrays:

```
INTEGER,ALLOCATABLE::matrix(:,:)
REAL, ALLOCATABLE:: vector(:)
```

```
. . .
ALLOCATE (matrix(3,5),vector(-2:N+2))
. . .
```

The following example allocates the scalar objects `s` and `t` to be 15 by 25 matrices with the value of `r`:

```
INTEGER J, N, ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)
...
ALLOCATE(A(0:80), B(-3:J+1, N), STAT = ALLOC_ERR)
```

The following example allocates `s` and `t` to be 15 by 25 arrays with the values of `r`:

```
REAL(KIND=8) :: r(15, 25)
REAL(KIND=8), ALLOCATABLE :: s(:,:), t(:,:)
...
ALLOCATE(s,SOURCE=r)
ALLOCATE(t,SOURCE=r)
```

ALLOCATORS

OpenMP* Fortran Compiler Directive: *Specifies memory allocators to be used to allocate variables in the associated Fortran ALLOCATE statement and to use in their deallocation. This feature is only available for ifx.*

Syntax

```
!$OMP ALLOCATORS [clause[[,] clause]... ]
   ALLOCATE statement
[!$OMP END ALLOCATORS]
```

clause — Is ALLOCATE.

An allocate object in the ALLOCATE statement cannot appear as a list item in more than one ALLOCATE clause in an ALLOCATORS directive. Each list item in the ALLOCATE clauses must have the ALLOCATABLE or POINTER attribute; therefore, it cannot be a common block name enclosed in slashes. Derived type components that have the ALLOCATABLE or POINTER attribute can appear as list items. List items cannot be associate names.

The ALLOCATORS construct associates an allocator with an allocate object in the associated ALLOCATE statement that is used for both allocation and deallocation of the object.

If an object appears as a list item of an ALLOCATE clause in an ALLOCATORS directive, it must also appear in the allocation list of the associated ALLOCATE statement. When an object is deallocated, it is deallocated using the same allocator used to allocate it. If an object is deallocated and reallocated during intrinsic

assignment, the same allocator is used for the deallocation and reallocation. Otherwise, the allocator specified for a list item is used to allocate the list item only in the ALLOCATE statement associated with the ALLOCATE directive, and to deallocate it, either explicitly or implicitly, when it goes out of scope.

If an allocate object in an ALLOCATE statement associated with an OpenMP ALLOCATE directive does not appear as a list item in the directive, the allocate object is ALLOCATED as if it appeared in a Fortran ALLOCATE statement that was not associated with an OpenMP ALLOCATE directive.

The functionality of the ALLOCATORS construct is also provided by the ALLOCATE directive form that is associated with a Fortran ALLOCATE statement; this is described in the ALLOCATE directive description as the second form of the ALLOCATE directive. If multiple allocators are to be used for an ALLOCATE statement, each allocator requires its own ALLOCATE directive. This form of the ALLOCATE directive has been deprecated and replaced by the ALLOCATORS construct.

ALLOCATED

Inquiry Intrinsic Function (Generic): *Indicates whether an allocatable array or allocatable scalar is currently allocated.*

Syntax

`result = ALLOCATED ([ARRAY=]`*`array`*`)`

`result = ALLOCATED ([SCALAR=]`*`scalar`*`)`

array	(Input) Must be an allocatable array.
scalar	(Input) Must be an allocatable scalar.

Results

The result is a scalar of type default logical.

The result has the value true if argument *array* or *scalar* is currently allocated; it has the value false if the argument is not currently allocated.

NOTE
When the argument keyword ARRAY is used, *array* must be an allocatable array. When the argument keyword SCALAR is used, *scalar* must be an allocatable scalar.

Example

```
REAL, ALLOCATABLE :: A(:)
...
IF (.NOT. ALLOCATED(A)) ALLOCATE (A (5))
```

Consider the following:

```
REAL, ALLOCATABLE, DIMENSION (:,:,:) :: E
PRINT *, ALLOCATED (E)       ! Returns the value false
ALLOCATE (E (12, 15, 20))
PRINT *, ALLOCATED (E)       ! Returns the value true
```

Arrays
Dynamic Allocation

ANINT

Elemental Intrinsic Function (Generic): *Calculates the nearest whole number.*

Syntax

```
result = ANINT (a[,kind] )
```

a	(Input) Must be of type real.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is real. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of *a*. If *a* is greater than zero, ANINT (*a*) has the value AINT (*a* + 0.5); if *a* is less than or equal to zero, ANINT (*a*) has the value AINT (*a* - 0.5).

Specific Name	Argument Type	Result Type
ANINT [1]	REAL(4)	REAL(4)
DNINT [1]	REAL(8)	REAL(8)
QNINT	REAL(16)	REAL(16)

[1]The setting of compiler options specifying real size can affect ANINT and DNINT.

To truncate rather than round, use AINT.

Example

ANINT (3.456) has the value 3.0.

ANINT (-2.798) has the value -3.0.

Consider the following:

```
      REAL r1, r2
      r1 = ANINT(2.6)     ! returns the value 3.0
      r2 = ANINT(-2.6)    ! returns the value -3.0

! Calculates and adds tax to a purchase amount.
      REAL amount, taxrate, tax, total
      taxrate = 0.081
      amount = 12.99
      tax = ANINT (amount * taxrate * 100.0) / 100.0
      total = amount + tax
      WRITE (*, 100) amount, tax, total
  100  FORMAT ( 1X, 'AMOUNT', F7.2 /
     + 1X, 'TAX ', F7.2 /
     + 1X, 'TOTAL ', F7.2)
      END
```

See Also

NINT

ANY

Transformational Intrinsic Function (Generic):
Determines if any value is true in an entire array or in a specified dimension of an array.

Syntax

`result = ANY (mask)`

`result = ANY (mask, dim)`

mask	(Input) Must be a logical array.
dim	(Input) Must be a scalar integer expression with a value in the range 1 to n, where *n* is the rank of *mask*.

Results

The result is an array or a scalar of type logical.

The result is a scalar if *dim* is not specified or *mask* has rank one. A scalar result is true if any elements of *mask* are true. The result has the value false if no element of *mask* is true, or *mask* has size zero.

An array result has the same type and kind parameters as *mask*, and a rank that is one less than *mask*. Its shape is (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *mask*.

Each element in an array result is true if any elements in the one dimensional array defined by *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) are true.

Example

```
    LOGICAL mask( 2, 3), AR1(3), AR2(2)
    logical, parameter :: T = .true.
    logical, parameter :: F = .false.
    DATA mask /T, T, F, T, F, F/
! mask is     true false false
!             true true false
    AR1 = ANY(mask,DIM = 1)  ! evaluates the elements column by
                             !   column yielding [true true false]
    AR2 = ANY(mask,DIM = 2)  ! evaluates the elements row by row
                             !   yielding [true true]
```

ANY ((/.FALSE., .FALSE., .TRUE./)) has the value true because one element is true.

A is the array

```
  [ 1  5  7 ]
  [ 3  6  8 ]
```

and B is the array

```
  [ 0  5  7 ]
  [ 2  6  9 ].
```

ANY (A .EQ. B, DIM=1) tests to see if any elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, true) because the second and third columns have at least one element that is equal.

ANY (A .EQ. B, DIM=2) tests to see if any elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (true, true) because each row has at least one element that is equal.

See Also

ALL
COUNT

ASIN

Elemental Intrinsic Function (Generic): *Produces the arcsine of an argument in radians.*

Syntax

```
result = ASIN (x)
```

x	(Input) Must be of type real, where | *x* | must be less than or equal to 1, or of type complex.

Results

The result type and kind are the same as *x*.

If the result is real, it is expressed in radians and lies in the range - pi/2 <= ASIN (x) <= pi/2.

If the result is complex, the real part is expressed in radians and lies in the range pi/2 <= REAL (ASIN (x)) <= pi/2.

Specific Name	Argument Type	Result Type
ASIN	REAL(4)	REAL(4)
DASIN	REAL(8)	REAL(8)
QASIN	REAL(16)	REAL(16)

Example

ASIN (0.79345021) has the value 0.9164571.

ASIND

Elemental Intrinsic Function (Generic): *Produces the arcsine of x in degrees.*

Syntax

```
result = ASIND (x)
```

x	(Input) Must be of type real. The | *x* | must be less than or equal to 1.

Results

The result type and kind are the same as *x* and are expressed in degrees. The value lies in the range −90 to 90 degrees.

Specific Name	Argument Type	Result Type
ASIND	REAL(4)	REAL(4)
DASIND	REAL(8)	REAL(8)

Specific Name	Argument Type	Result Type
QASIND	REAL(16)	REAL(16)

Example

ASIND (0.2467590) has the value 14.28581.

ASINH

Elemental Intrinsic Function (Generic): *Produces the hyperbolic arcsine of x.*

Syntax

```
result = ASINH (x)
```

x (Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*.

If the result is complex, the imaginary part is expressed in radians and lies in the range - pi/ 2 <= AIMAG (ASINH (x)) <= pi / 2.

Specific Name	Argument Type	Result Type
ASINH	REAL(4)	REAL(4)
DASINH	REAL(8)	REAL(8)
QASINH	REAL(16)	REAL(16)

Example

ASINH (1.0) has the value -0.88137.

ASINH (180.0) has the value 5.88611.

ASSIGN - Label Assignment

Statement: *Assigns a statement label value to an integer variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.*

Syntax

```
ASSIGN label TO var
```

label Is the label of a branch target or FORMAT statement in the same scoping unit as the ASSIGN statement.

var Is a scalar integer variable.

When an ASSIGN statement is executed, the statement label is assigned to the integer variable. The variable is then undefined as an integer variable and can only be used as a label (unless it is later redefined with an integer value).

The ASSIGN statement must be executed before the statements in which the assigned variable is used.

Indirect branching through integer variables makes program flow difficult to read, especially if the integer variable is also used in arithmetic operations. Using these statements permits inconsistent usage of the integer variable, and can be an obscure source of error. The ASSIGN statement was used to simulate internal procedures, which now can be coded directly.

Example

The value of a label is not the same as its number; instead, the label is identified by a number assigned by the compiler. In the following example, 400 is the label number (not the value) of IVBL:

```
ASSIGN 400 TO IVBL
```

Variables used in ASSIGN statements are not defined as integers. If you want to use a variable defined by an ASSIGN statement in an arithmetic expression, you must first define the variable by a computational assignment statement or by a READ statement, as in the following example:

```
IVBL = 400
```

The following example shows ASSIGN statements:

```
INTEGER ERROR
...
ASSIGN 10 TO NSTART
ASSIGN 99999 TO KSTOP
ASSIGN 250 TO ERROR
```

Note that NSTART and KSTOP are integer variables implicitly, but ERROR must be previously declared as an integer variable.

The following statement associates the variable NUMBER with the statement label 100:

```
ASSIGN 100 TO NUMBER
```

If an arithmetic operation is subsequently performed on variable NUMBER (such as follows), the runtime behavior is unpredictable:

```
NUMBER = NUMBER + 1
```

To return NUMBER to the status of an integer variable, you can use the following statement:

```
NUMBER = 10
```

This statement dissociates NUMBER from statement 100 and assigns it an integer value of 10. Once NUMBER is returned to its integer variable status, it can no longer be used in an assigned GO TO statement.

Assignment: intrinsic

Obsolescent Language Features in the Fortran Standard

Assignment(=) - Defined Assignment

Statement: *An interface block that defines generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.*

Syntax

The initial line for such an interface block takes the following form:

```
INTERFACE ASSIGNMENT (=)
```

Description

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN and/or attribute VALUE.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment, enclosed in parentheses, corresponds to the second argument. A defined assignment procedure with an ALLOCATABLE or POINTER dummy argument cannot be directly invoked through defined assignment; the right-hand side of the assignment operator becomes an expression, and an expression cannot have the ALLOCATABLE, POINTER, or TARGET attribute.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

Example

The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN)  :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC
  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE                   ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR    ! A variable-length string
    CHARACTER(*), INTENT(IN)  :: CHAR
  END SUBROUTINE  CHAR_TO_STRING
END  INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
  CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
  X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```
  CALL CHAR_TO_STRING(CH, '432C')
  CH = '432C'
```

The following is an example of a declaration and reference to a defined assignment:

```
!Converting circle data to interval data.
module mod1
TYPE CIRCLE
        REAL radius, center_point(2)
END TYPE CIRCLE
TYPE INTERVAL
        REAL lower_bound, upper_bound
END TYPE INTERVAL
CONTAINS
        SUBROUTINE circle_to_interval(I,C)
          type (interval),INTENT(OUT)::I
          type (circle),INTENT(IN)::C
!Project circle center onto the x=-axis
!Note: the length of the interval is the diameter of the circle
                I%lower_bound = C%center_point(1) - C%radius
                I%upper_bound = C%center_point(1) + C%radius
        END SUBROUTINE circle_to_interval
```

```
end module mod1

PROGRAM assign
use mod1
TYPE(CIRCLE) circle1
TYPE(INTERVAL) interval1
INTERFACE ASSIGNMENT(=)
        module procedure circle_to_interval
END INTERFACE
!Begin executable part of program
  circle1%radius = 2.5
  circle1%center_point = (/3.0,5.0/)
  interval1 = circle1
. . .
END PROGRAM
```

INTERFACE

Assignment Statements

Assignment - Intrinsic Computational

Statement: *Assigns a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.*

Syntax

variable=expression

variable	Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.
expression	Is of intrinsic type or the same derived type as *variable*. Its shape must conform with *variable*. If necessary, it is converted to the same type and kind as *variable*.

Description

Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

> **NOTE**
> When the runtime system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the runtime system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

If the !DIR$ NOSTRICT compiler directive (the default) is in effect, then you can assign a character expression to a noncharacter variable, and a noncharacter variable or array element (but not an expression) to a character variable.

Example

```
    REAL a, b, c
    LOGICAL abigger
    CHARACTER(16) assertion
    c = .01
    a = SQRT (c)
    b = c**2
    assertion = 'a > b'
    abigger = (a .GT. b)
    WRITE (*, 100) a, b
100 FORMAT (' a =', F7.4, ' b =', F7.4)
    IF (abigger) THEN
            WRITE (*, *) assertion, ' is true.'
    ELSE
            WRITE (*, *) assertion, ' is false.'
    END IF
    END
! The program above has the following output:
!     a =    .1000     b =   .0001         a > b is true.
! The following code shows legal and illegal
! assignment statements:
!
    INTEGER i, j
    REAL rone(4), rtwo(4), x, y
    COMPLEX z
    CHARACTER name6(6), name8(8)
    i         = 4
    x         = 2.0
    z         = (3.0, 4.0)
    rone(1) = 4.0
    rone(2) = 3.0
    rone(3) = 2.0
    rone(4) = 1.0
    name8   = 'Hello,'

! The following assignment statements are legal:
    i     = rone(2); j = rone(i); j = x
    y     = x; y = z; y = rone(3); rtwo = rone; rtwo = 4.7
    name6 = name8

! The following assignment statements are illegal:
    name6 = x + 1.0; int = name8//'test'; y = rone
    END
```

Assignment: defined
NOSTRICT directive

ASSOCIATE

Statement: *Marks the beginning of an ASSOCIATE construct. The ASSOCIATE construct creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.*

Syntax

```
[name:] ASSOCIATE (assoc-entity[, assoc-entity]...)
   block
END ASSOCIATE [name]
```

name — (Optional) Is the name of the ASSOCIATE construct.

assoc-entity — Is *associate-name => selector*

- *associate-name* — Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct.
- *selector* — Is an expression or variable. It becomes the associated entity.

block — Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an ASSOCIATE statement, the same name must appear in the corresponding END ASSOCIATE statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of an ASSOCIATE statement, you cannot specify one following the END ASSOCIATE statement.

During execution of the block within the construct, each *associate-name* identifies an entity, which is associated with the corresponding *selector*. The associating entity assumes the declared type and type parameters of the selector.

You can only branch to an END ASSOCIATE statement from within its ASSOCIATE construct.

This construct is useful when you want to simplify multiple accesses to a variable that has a lengthy description; for example, if the variable contains multiple subscripts and component names.

Example

The following shows an expression as a selector:

```
ASSOCIATE (O => (A-F)**2 + (B+G)**2)
  PRINT *, SQRT (O)
END ASSOCIATE
```

The following shows association with an array section:

```
ASSOCIATE (ARRAY => AB % D (I, :) % X)
  ARRAY (3) = ARRAY (1) + ARRAY (2)
END ASSOCIATE
```

Without the ASSOCIATE construct, this is what you would need to write:

```
AB % D (I, 3) % X = AB % D (I, 1) % X + AB % D (I, 2) % X
```

See Also

Construct Association
Additional Attributes Of Associate Names

ASSOCIATED

Inquiry Intrinsic Function (Generic): *Returns the association status of its pointer argument or indicates whether the pointer is associated with the target.*

Syntax

`result = ASSOCIATED (pointer [, target])`

pointer	(Input) Must be a pointer. It can be of any data type. The pointer association status must be defined.
target	(Input; optional) Must be a pointer or target. If it is a pointer, the pointer association status must be defined.

Results

The result is a scalar of type default logical. The setting of compiler options specifying integer size can affect this function.

If only *pointer* appears, the result is true if it is currently associated with a target; otherwise, the result is false.

If *target* also appears and is a target, the result is true if *pointer* is currently associated with *target*; otherwise, the result is false.

If *target* is a pointer, the result is true if both *pointer* and *target* are currently associated with the same target; otherwise, the result is false. (If either *pointer* or *target* is disassociated, the result is false.)

Example

```
REAL C (:), D(:), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
C => E                        ! pointer assignment
D => E                        ! pointer assignment
STATUS = ASSOCIATED(C)        ! returns TRUE; C is associated
STATUS = ASSOCIATED(C, E)     ! returns TRUE; C is associated with E
STATUS = ASSOCIATED (C, D)    ! returns TRUE; C and D are associated
                              !   with the same target
```

Consider the following:

```
   REAL, TARGET, DIMENSION (0:50) :: TAR
   REAL, POINTER, DIMENSION (:) :: PTR
   PTR => TAR
   PRINT *, ASSOCIATED (PTR, TAR)      ! Returns the value true
```

The subscript range for PTR is 0:50. Consider the following pointer assignment statements:

```
   (1) PTR => TAR (:)
   (2) PTR => TAR (0:50)
   (3) PTR => TAR (0:49)
```

For statements 1 and 2, ASSOCIATED (PTR, TAR) is true because TAR has not changed (the subscript range for PTR in both cases is 1:51, following the rules for deferred-shape arrays). For statement 3, ASSOCIATED (PTR, TAR) is false because the upper bound of TAR has changed.

Consider the following:

```
REAL, POINTER, DIMENSION (:) :: PTR2, PTR3
ALLOCATE (PTR2 (0:15))
PTR3 => PTR2
PRINT *, ASSOCIATED (PTR2, PTR3)       ! Returns the value true
...
NULLIFY (PTR2)
NULLIFY (PTR3)
PRINT *, ASSOCIATED (PTR2, PTR3)       ! Returns the value false
```

ASSUME

General Compiler Directive: *Provides heuristic information to the compiler optimizer.*

Syntax

`!DIR$ ASSUME (`*`scalar-logical-expression`*`)`

`scalar-logical-expression` Is any expression that evaluates to .TRUE. or .FALSE. at runtime.

At compile time, the *scalar-logical-expression* is always presumed to be true and may be used by the optimizer to generate better code.

At runtime, the ASSUME directive is evaluated at the point where it is located in the source.

If the `check assume` option is specified and *scalar-logical-expression* does not evaluate to .TRUE. at runtime, an error message is displayed and execution is aborted. If the `check assume` option is *not* specified and *scalar-logical-expression* does not evaluate to .TRUE. at runtime, program behavior is undefined.

Example

In the example below, the compiler is told that A is aligned on a 32-byte boundary using the ASSUME_ALIGNED directive. The ASSUME directive says that the length of the first dimension of A is a multiple of 8. Therefore the optimizer knows that A(I,J+1) and A(I,J-1) are 0 mod 64 bytes away from A(I,J) and are therefore also aligned on 32-byte boundaries. This information helps the optimizer in generating efficiently vectorized code for these loops.

```
SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ ASSUME (MOD(NX,8) .EQ. 0)
! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
DO J=J1,J2
  DO I=I1,I2
     A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
  ENDDO
ENDDO
END SUBROUTINE F
```

General Compiler Directives

Syntax Rules for Compiler Directives
ASSUME_ALIGNED directive
check compiler option (setting assume)

ASSUME_ALIGNED

General Compiler Directive: *Specifies that an entity in memory is aligned.*

Syntax

```
!DIR$ ASSUME_ALIGNED address1:n1 [, address2:n2]...
```

address — An array variable. It can be of any data type, kind, or rank > 0. It can be an array component of a variable of derived type or a record field reference, host or use associated, or have the ALLOCATABLE or POINTER attribute.

It cannot be any of the following:

- An entity in COMMON (or an entity EQUIVALENCEd to something in COMMON)
- A component of a variable of derived type or a record field reference
- An entity accessed by use or host association

If it is a module variable, that address is silently ignored.

n — A positive integer constant expression. Its value must be a power of 2 between 1 and 256, that is, 1, 2, 4, 8, 16, 32, 64, 128, 256. It specifies the memory alignment in bytes of *address*.

The ASSUME_ALIGNED directive must appear after the specification statements section or inside the executable statements section.

If you specify more than one *address*:*n* item, they must be separated by a comma.

If *address* is a Cray POINTER or it has the POINTER attribute, it is the POINTER and not the pointee or the TARGET that is assumed aligned.

If the check assume option is specified and *address* is not aligned on an *n*-byte boundary at runtime, an error message is displayed and execution is aborted.

For more information, see the example in the description of the ASSUME directive.

Example

The following example shows the correct placement and usage of the ASSUME_ALIGNED directive:

```
SUBROUTINE F(A, N)
  TYPE NODE
    REAL(KIND=8), POINTER :: A(:,:)
  END TYPE NODE

  TYPE(NODE), POINTER :: NODES

  ALLOCATE(NODES)
  ALLOCATE(NODES%A(1000,1000))

!DIR$ ASSUME_ALIGNED NODES%A(1,1) : 16
  DO I=1,N
    NODES%A(1,I) = NODES%A(1,I)+1
```

```
  ENDDO
…
END
```

It is illegal to place ASSUME_ALIGNED inside a type definition; for example:

```
TYPE S
!DIR$ ASSUME_ALIGNED T : 16          ! this is an error
  REAL(8), ALLOCATABLE :: T(:)
END TYPE S
```

ASSUMES Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Provides hints to the optimizer about the current compilation unit and all the code it can reach through procedure calls. This feature is only available for ifx.*

Syntax

`!$OMP ASSUMES` *`clause`*`[[[,] clause]... ]`

`clause` Is an ASSUMPTION clause.

The ASSUMES directive is an informational directive that provides optimization hints to the compiler. The scope of the directive is the code executed in the current compilation unit, and all code that can be reached from the current compilation unit through procedure calls. It is a pure directive, so it can appear in a Fortran PURE procedure.

The ASSUMES directive must appear in the specification part of a module or subprogram, following all IMPLICIT, IMPORT, or USE statements.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
ASSUMPTION clause directive

ASSUMPTION Clause

Parallel Directive Clause: *Specifies information about the expected properties of a program that can be used by the compiler for optimization. This feature is only available for ifx.*

Syntax

`assumption-clause`

`assumption-clause` Is one of the following:

`ABSENT` (*directive-name* [[, *directive-name*]...])	Tells the compiler that *directive-name* does not match any construct encountered in the scope of the directive containing this clause.
`CONTAINS` (*directive-name* [[, *directive-name*]...])	Hints to the compiler that *directive-name* is assumed to match at least one construct within the scope of the directive containing this clause.
`HOLDS` (*scalar-logical-expression*)	Tells the compiler that the *scalar-logical-expression* evaluates to .TRUE. in the scope of the directive containing this clause. The *scalar-logical-expression* is not evaluated by the clause and has no observable effect by appearing in the clause.
`NO_OPENMP`	Tells the compiler that there is no OpenMP* code to be executed in the scope of the directive containing this clause.
`NO_OPENMP_ROUTINES`	Tells the compiler that no OpenMP runtime routines are called from within the scope of the directive containing this clause.
`NO_PARALLELISM`	Tells the compiler the following: • There will not be any OpenMP implicit or explicit tasks generated by execution of the code in the scope of the directive containing this clause. • No SIMD constructs are executed in the scope of the directive containing this clause.

The NO_OPENMP, NO_OPENMP_ROUTINES, and NO_PARALLELISM clauses can appear at most once in a directive.

directive-name

Is an OpenMP executable directive name that is not an END *directive-name* directive. It cannot be a declarative, loop transformation, informational, or a non-executable utility directive.

A *directive-name* listed in an *assumption-clause* can appear at most once in the directive. You cannot specify a combined or composite directive name.

Description

If the assumptions specified by any of the *assumption-clause*s are incorrect, the program behavior is unspecified.

A construct matches *directive-name* if it has the same name as *directive-name*, or if it is a combined construct with a constituent construct that has a name that matches *directive-name*.

ASSUMES Directive

ASYNCHRONOUS

Statement and Attribute: *Specifies that a variable can be used for asynchronous input and output.*

Syntax

The ASYNCHRONOUS attribute can be specified in a type declaration statement or an ASYNCHRONOUS statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] ASYNCHRONOUS [, *att-ls*] :: *var* [, *var*] ...

Statement:

ASYNCHRONOUS [::] *var* [, *var*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
var	Is the name of a variable.

Description

Asynchronous I/O, or non-blocking I/O, allows a program to continue processing data while the I/O operation is performed in the background.

A variable can have the ASYNCHRONOUS attribute in a particular scoping unit without necessarily having it in other scoping units. If an object has the ASYNCHRONOUS attribute, then all of its subobjects also have the ASYNCHRONOUS attribute.

The ASYNCHRONOUS attribute can also be implied by use of a variable in an asynchronous READ or WRITE statement.

You can specify variables that are used for asynchronous communication, such as with Message Passing Interface Standard (MPI). Asynchronous communication has the following restrictions:

- For input, a pending communication affector must not be referenced, become defined, become undefined, become associated with a dummy argument that has the VALUE attribute, or have its pointer association status changed.
- For output, a pending communication affector must not be redefined, become undefined, or have its pointer association status changed.

Examples

The following example shows how the ASYNCHRONOUS attribute can be applied in an OPEN and READ statement.

```
program test
integer, asynchronous, dimension(100) :: array
open (unit=1,file='asynch.dat',asynchronous='YES',&
  form='unformatted')
write (1) (i,i=1,100)
rewind (1)
read (1,asynchronous='YES') array
wait(1)
write (*,*) array(1:10)
end
```

Type Declarations
Compatible attributes

ATAN

Elemental Intrinsic Function (Generic): *Produces the arctangent of an argument in radians.*

Syntax

```
result = ATAN (x)
result = ATAN (y,x)
```

y	(Input) Must be of type real.
x	(Input) If *y* appears, *x* must be of type real with the same kind type parameter as *y*. If *y* has the value zero, *x* must not have the value zero. If *y* does not appear, *x* must be of type real or complex.

Results

The result type and kind are the same as *x*.

If *y* appears, the result is the same as the result of ATAN2 (y, x).

If *y* does not appear, the real part of the result is expressed in radians and lies in the range -pi/2 <= ATAN (x) <= pi/2.

Specific Name	Argument Type	Result Type
ATAN	REAL(4)	REAL(4)
DATAN	REAL(8)	REAL(8)
QATAN	REAL(16)	REAL(16)

Example

ATAN (1.5874993) has the value 1.008666.

ATAN (2.679676, 1.0) has the value 1.213623.

ATAN2

Elemental Intrinsic Function (Generic): *Produces an arctangent (inverse tangent) in radians. The result is the principal value of the argument of the nonzero complex number (x, y).*

Syntax

```
result = ATAN2 (y,x)
```

y	(Input) Must be of type real.
x	(Input) Must have the same type and kind parameters as *y*. If *y* has the value zero, *x* cannot have the value zero.

Results

The result type and kind are the same as *x* and are expressed in radians. The value lies in the range -pi <= ATAN2 (*y*, *x*) <= pi.

If *x* is not zero, the result is approximately equal to the value of arctan (*y*/ *x*).

If *y* > zero, the result is positive.

If *y* < zero, the result is negative.

If *y* is zero and *x* > zero, the result is *y* (so for x>0, ATAN2 ((+0.0), x) is +0.0 and ATAN2 ((-0.0), x) is -0.0).

If *y* is a positive real zero and *x* < zero, the result is pi.

If *y* is a negative real zero and *x* < zero, the result is -pi.

If *x* is a positive real zero, the result is pi/2.

If *y* is a negative real zero, the result is -pi/2.

Specific Name	Argument Type	Result Type
ATAN2	REAL(4)	REAL(4)
DATAN2	REAL(8)	REAL(8)
QATAN2	REAL(16)	REAL(16)

Example

ATAN2 (2.679676, 1.0) has the value 1.213623.

If Y is an array that has the value

```
[  1   1 ]
[ -1  -1 ]
```

and X is an array that has the value

```
[ -1  1 ]
[ -1  1 ],
```

then ATAN2 (Y, X) is

$$\begin{bmatrix} \frac{3pi}{4} & \frac{pi}{4} \\ \frac{-3pi}{4} & \frac{-pi}{4} \end{bmatrix}$$

ATAN2D

Elemental Intrinsic Function (Generic): *Produces an arctangent in degrees. The result is the principal value of the argument of the nonzero complex number (x, y).*

Syntax

`result = ATAN2D (y,x)`

y	(Input) Must be of type real.
x	(Input) Must have the same type and kind parameters as *y*. If *y* has the value zero, *x* cannot have the value zero.

Results

The result type and kind are the same as *x* and are expressed in degrees. The value lies in the range -180 degrees to 180 degrees. If *x* zero, the result is approximately equal to the value of arctan (*y*/ *x*).

If *y* > zero, the result is positive.

If *y* < zero, the result is negative.

If *y* = zero, the result is zero (if *x* > zero) or 180 degrees (if *x* < zero).

If *x* = zero, the absolute value of the result is 90 degrees.

Specific Name	Argument Type	Result Type
ATAN2D	REAL(4)	REAL(4)
DATAN2D	REAL(8)	REAL(8)
QATAN2D	REAL(16)	REAL(16)

Example

ATAN2D (2.679676, 1.0) has the value 69.53546.

ATAND

Elemental Intrinsic Function (Generic): *Produces the arctangent of x in degrees.*

Syntax

It can take one of the following forms:

```
result = ATAND (x)
```

-or-

```
result = ATAND (y, x)
```

y	(Input; optional) If specified, it must be of type real and have the same KIND parameter as *x*.
x	(Input) Must be of type real. If *y* appears and has the value 0.0, *x* must not have the value 0.0.

Results

If *y* appears, the result is the same as the result of ATAN2D (*y*, *x*). Otherwise, the result type and kind are the same as *x* and are expressed in degrees between ±90°.

There are no specific names for the two argument form of this function.

Specific Name	Argument Type	Result Type
ATAND (*x*)	REAL(4)	REAL(4)
DATAND (*x*)	REAL(8)	REAL(8)
QATAND (*x*)	REAL(16)	REAL(16)

Example

ATAND (0.0874679) has the value 4.998819.

ATANH

Elemental Intrinsic Function (Generic): *Produces the hyperbolic arctangent of x.*

Syntax

```
result = ATANH (x)
```

x (Input) Must be of type real, where | *x* | is less than or equal to 1, or of type complex.

Results

The result type and kind are the same as *x*.

If the result is real, it lies in the range -1.0 < ATANH (x) < 1.0.

If the result is complex, the imaginary part is expressed in radians and lies in the range –pi/2 <= AIMAG (ATANH (x)) <= pi/2.

Specific Name	Argument Type	Result Type
ATANH	REAL(4)	REAL(4)
DATANH	REAL(8)	REAL(8)
QATANH	REAL(16)	REAL(16)

Example

ATANH (-0.77) has the value -1.02033.

ATANH (0.5) has the value 0.549306.

ATOMIC

OpenMP* Fortran Compiler Directive: *Ensures that a specific memory location is updated atomically. This prevents the possibility of multiple threads simultaneously reading and writing the specific memory location.*

Syntax

```
!$OMP ATOMIC [clause[[[,] clause]...]]
   block
[!$OMP END ATOMIC]
```

clause (Optional) Is one of the following:

- An *atomic-clause*, which is one of the following:
  - READ
  - UPDATE
  - WRITE

  For details on the effects of these clauses, see the table in the Description section.
- A *memory-order-clause*, which is one of the following:
  - ACQ_REL

    Specifies both an ACQUIRE and a RELEASE flush.
  - ACQUIRE

Forces consistency between views of memory of two synchronizing threads by discarding any value of a shared variable in its temporary view, which the thread has not written since last performing a RELEASE flush.

It also will reload any value of a shared variable propagated by a RELEASE flush that synchronizes with it.

- RELAXED

  Permits a thread's local or temporary view of memory, which may be held in registers, cache, or other local memory, to be temporarily inconsistent with the memory, which may have been updated by another thread.

  Note that a strong flush operation forces consistency between memory and a threads temporary view and memory, and it restricts reordering of memory operations that may otherwise be performed. RELAXED memory ordering has no implicit flushes.
- RELEASE

  Forces consistency between views of memory of two synchronizing threads by guaranteeing that any prior READ or WRITE of a shared variable will appear complete before any READ or WRITE of the same shared variable that follows an ACQUIRE flush that is synchronized with a RELEASE flush.

  The RELEASE flush propagates the values of all shared variables in its temporary view of memory prior to the thread performing a subsequent atomic operation that establishes a synchronization.
- SEQ_CST

  Specifies that the construct is a *sequentially consistent atomic construct*. Unlike non-sequentially consistent atomic constructs, sequentially consistent atomic constructs preserve the interleaving (sequentially consistent) behavior of correct, data-race-free programs.

  However, sequentially consistent atomic constructs are not designed to replace the FLUSH directive as a mechanism to enforce ordering for non-sequentially consistent atomic constructs. Attempts to do so require extreme caution.

  For example, a sequentially consistent ATOMIC WRITE construct may appear to be reordered with a subsequent non-sequentially consistent ATOMIC WRITE construct because such reordering would not be observable by a correct program if the second WRITE was outside an ATOMIC construct.

If a *memory-order-clause* is present, or implicitly provided by a REQUIRES directive, it specifies the effective memory ordering; otherwise, the effective memory ordering is RELAXED.

- Or one of the following:
  - CAPTURE

Causes an atomic update to *x* to occur using the specified *operator* or *intrinsic*. The original or final value of the location *x* is captured and written to the storage location *v*.

Only the READ and WRITE of the location specified by *x* are performed mutually atomically. The evaluation of *expr* or *expr-list* and the write to *v* need not be atomic with respect to the READ and WRITE of *x*.

- COMPARE

  Specifies that the atomic update is a conditional atomic update. If the equality *operator* is used, the operation is an atomic compare and swap.

  The values of *x* and *e* are compared and if equal, the value of *d* is written to *x*. The original or final value of *x* is written to *v*, which may be the same as *e*.

  Only the READ and WRITE of *x* is performed atomically; neither the comparison nor the writes to *v* need be atomic with respect to the READ or WRITE of *x*.
- HINT (hint-expression)
- FAIL (SEQ_CAT | ACQUIRE |RELAXED)

  Specifies that its parameter overrides the effective memory ordering used when the comparison for a conditional update fails.
- WEAK

  Indicates that the comparison performed by an atomic compare and swap may falsely fail, evaluating to not equal even when the values are equal.

block

Is one of the following:

- *statement*
- or if CAPTURE is also specified, it can be the following:
  - *statement*
  - *capture-statement*

  The order is not important. *capture-statement* can appear before *statement*.

statement

Is one of the following:

- *capture-statement* - if *atomic-clause* is READ, or *atomic-clause* is UPDATE with CAPTURE also specified
- *compare-statement* - if the COMPARE clause is present
- *update-statement* - if *atomic-clause* is UPDATE
- *write-statement* - if *atomic-clause* is WRITE, or *atomic-clause* is UPDATE with CAPTURE also specified

capture-statement

Is an expression in the form *v* = *x*.

compare-statement

Is as follows:

```
if (x == e) then
   x = d
end
```

or:

```
if (x == e) x = d
```

or if CAPTURE also appears and *block* contains no *capture-statement* it can also be the following:

```
if (x == e) then
   x = d
else
   v = x
end if
```

update-statement

Is an expression with one of the following forms:

```
x = x operator expr
x = expr operator x
x = intrinsic (x, expr-list)
x = intrinsic (expr-list, x)
```

The following rules apply:

- Operators in *expr* must have precedence equal to or greater than the precedence of *operator*, and cannot be defined operators.
- *xoperatorexpr* must be mathematically equivalent to *xoperator* (*expr*). This requirement is satisfied if the *operator*s in *expr* have precedence greater than *operator*, or by using parentheses around *expr* or subexpressions of *expr*.
- *exproperatorx* must be mathematically equivalent to (*expr*) *operatorx*. This requirement is satisfied if the *operator*s in *expr* have precedence equal to or greater than *operator*, or by using parentheses around *expr* or subexpressions of *expr*.
- All assignments must be intrinsic assignments.

write-statement

Is an expression in the form *x* = *expr*.

d, e, x, v

Are scalar variables of intrinsic type. During execution of an atomic region, all references to storage location *x* must specify the same storage location.

v must not access the same storage location as *x*.

expr, expr-list

expr is a scalar expression. *expr-list* is a comma-separated list of expressions. They must not access the same storage location as *x* or *v*.

If *intrinsic* is IAND, IOR, or IEOR, then *expr-list* can contain only one expression.

operator

Is one of the following intrinsic operators: +, *, -, /, ,AND., ,OR., .EQV., or .NEQV..

intrinsic

Is one of the following intrinsic procedures: MAX, MIN, IAND, IOR, or IEOR.

If *x* is of size 8, 16, 32, or 64 bits and *x* is aligned to a multiple of its size, the binding thread set is all threads on the device. Otherwise, the binding thread set is all threads in the contention group. Atomic regions enforce exclusive access with respect to other atomic regions that access the same storage location *x* among all the threads in the binding thread set without regard to the teams to which the threads belong.

If !$OMP ATOMIC is specified with no *atomic-clause*, it is the same as specifying !$OMP ATOMIC UPDATE.

If !$OMP ATOMIC CAPTURE is specified, you must include an !$OMP END ATOMIC directive following the *block*. Otherwise, the !$OMP END ATOMIC directive is optional.

Note that the following restriction applies to the ATOMIC directive:

- All atomic accesses to the storage locations designated by *x* throughout the program must have the same type and type parameters.

The following table describes what happens when you specify one of the values in the *atomic-clause* in an ATOMIC construct.

Clause	Result
READ	Causes an atomic read of the location designated by *x* regardless of the native machine word size.
UPDATE	Causes an atomic update of the location designated by *x* using the designated *operator* or *intrinsic*. The following rules also apply: • The evaluation of *expr* or *expr-list* need not be atomic with respect to the READ or WRITE of the location designated by *x*. • No task scheduling points are allowed between the READ and the WRITE of the location designated by *x*.
WRITE	Causes an atomic write of the location designated by *x* regardless of the native machine word size.

If all of the following conditions are true, the strong flush on entry to the atomic operation is also a RELEASE flush:

- The *atomic-clause* is WRITE or UPDATE.
- The atomic operation is not a conditional update for which the comparison fails.
- The effective memory ordering is RELEASE, ACQ_REL, or SEQ_CST.

If both of the following conditions are true, the strong flush on exit from the atomic operation is also an ACQUIRE flush:

- The *atomic-clause* is READ or UPDATE.
- The effective memory ordering is ACQUIRE, ACQ_REL, or SEQ_CST.

Therefore, as the above shows, the effective memory ordering is not RELAXED. RELEASE and ACQUIRE flushes can be implied and permit synchronization between threads without an explicit FLUSH directive.

Any combination of two or more of these atomic constructs enforces mutually exclusive access to the locations designated by *x*.

A race condition exists when two unsynchronized threads access the same shared variable with at least one thread modifying the variable; this can cause unpredictable results. To avoid race conditions, all accesses of the locations designated by *x* that could potentially occur in parallel must be protected with an ATOMIC construct.

Atomic regions do not guarantee exclusive access with respect to any accesses outside of atomic regions to the same storage location *x* even if those accesses occur during a CRITICAL or ORDERED region, while an OpenMP* lock is owned by the executing task, or during the execution of a REDUCTION clause.

However, other OpenMP* synchronization can ensure the desired exclusive access. For example, a BARRIER directive following a series of atomic updates to *x* guarantees that subsequent accesses do not form a race condition with the atomic accesses.

Example

The following example shows a way to avoid race conditions by using ATOMIC to protect all simultaneous updates of the location by multiple threads.

Since the ATOMIC directive below applies only to the statement immediately following it, elements of `Y` are not updated atomically.

```
   REAL FUNCTION FOO1(I)
      INTEGER I
      FOO1 = 1.0 * I
      RETURN
   END FUNCTION FOO1

   REAL FUNCTION FOO2(I)
      INTEGER I
      FOO2 = 2.0 * I
      RETURN
   END FUNCTION FOO2

   SUBROUTINE SUB(X, Y, INDEX, N)
      REAL X(*), Y(*)
      INTEGER INDEX(*), N
      INTEGER I
!$OMP PARALLEL DO SHARED(X, Y, INDEX, N)
      DO I=1,N
!$OMP ATOMIC UPDATE
         X(INDEX(I)) = X(INDEX(I)) + FOO1(I)
         Y(I) = Y(I) + FOO2(I)
      ENDDO
   END SUBROUTINE SUB

   PROGRAM ATOMIC_DEMO
      REAL X(1000), Y(10000)
      INTEGER INDEX(10000)
      INTEGER I
      DO I=1,10000
         INDEX(I) = MOD(I, 1000) + 1
         Y(I) = 0.0
      ENDDO
      DO I = 1,1000
         X(I) = 0.0
      ENDDO
      CALL SUB(X, Y, INDEX, 10000)
   END PROGRAM ATOMIC_DEMO
```

The following non-conforming example demonstrates the restriction on the ATOMIC construct:

```
   SUBROUTINE ATOMIC_INCORRECT()
      INTEGER:: I
      REAL:: R
      EQUIVALENCE(I,R)
!$OMP PARALLEL
!$OMP ATOMIC UPDATE
      I = I + 1
!$OMP ATOMIC UPDATE
      R = R + 1.0
! The above is incorrect because I and R reference the same location
```

```
! but have different types
!$OMP END PARALLEL
   END SUBROUTINE ATOMIC_INCORRECT
```

ATOMIC_ADD

Atomic Intrinsic Subroutine (Generic): *Performs atomic addition.*

Syntax

`CALL ATOMIC_ADD (atom, value [, stat])`

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of *atom* + *value* if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* and *value* + *atom* must be representable as integers with kind ATOMIC_INT_KIND.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_ADD (N[12], 7)
```

If N on image 12 is 4 when this operation is initiated, the value of N on image 12 is defined with the value 11 when the operation is complete and no error occurs during the subroutine reference.

ISO_FORTRAN_ENV Module

ATOMIC_AND

Atomic Intrinsic Subroutine (Generic): *Performs atomic bitwise AND.*

Syntax

CALL ATOMIC_AND (*atom*, *value* [, *stat*])

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `iand` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_AND (N[4], 22)
```

If the value of N on image 4 is 29 when this operation is initiated, the value of N on image 4 is 20 when the operation is complete and no error condition occurs during the subroutine reference.

ATOMIC_CAS

Atomic Intrinsic Subroutine (Generic): *Performs atomic compare and swap.*

Syntax

CALL ATOMIC_CAS (*atom*, *old*, *compare*, *new* [, *stat*])

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or type logical with kind ATOMIC_LOGICAL_KIND. *atom* becomes undefined if an error occurs. Otherwise, if *atom* is of type integer and equal to *compare*, or of type logical and equivalent to *compare*, it becomes defined with the value *new*. If *atom* is of type logical and has been assigned a value other than .true. or .false., the result is undefined. ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.
old	(Output) Must be a scalar of the same type as *atom*. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value *atom* has at the beginning of the atomic operation.
compare	(Input) Must be scalar and the same type and kind as *atom*.
new	(Input) Must be scalar and the same type and kind as *atom*.

stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_CAS (N[4], I, 8, 10)
```

If the value of N on image 4 is 8 when the atomic operation is initiated, N on image 4 is defined with the value 10, and I is defined with the value 8 when the operation is complete and no error occurs during the subroutine reference. If the value N on image 4 is 13 when the atomic operation is initiated, the value of N is unchanged, and the value of I is 13 when the operation completes and no error condition occurs during the procedure reference.

ATOMIC_DEFINE

Atomic Intrinsic Subroutine (Generic): *Defines a variable atomically.*

Syntax

```
CALL ATOMIC_DEFINE (atom, value [, stat])
```

atom	(Output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND. If its kind is the same as that of value or its type is logical, it becomes defined with the value of *value*. Otherwise, it becomes defined with the value of INT (VALUE, ATOMIC_INT_KIND). ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar and of the same type as *atom*.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_DEFINE (N[9], 7)
```

This causes N on image 9 to become defined with the value 7.

ATOMIC_FETCH_ADD

Atomic Intrinsic Subroutine (Generic): *Performs atomic fetch and addition.*

Syntax

```
CALL ATOMIC_FETCH_ADD (atom, value, old [, stat])
```

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of *atom* + *value* if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* and *value* + *atom* must be representable as integers with kind ATOMIC_INT_KIND.
old	(Output) Must be a scalar of the same type as *atom*. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value *atom* has at the beginning of the atomic operation.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_FETCH_ADD (N[4], 8, M)
```

If the value of N on image 4 was 7 when the atomic operation is initiated, N on image 4 is defined with the value 15, and M becomes is defined with the value 7 when the operation completes and no error occurs during the subroutine reference.

ATOMIC_FETCH_AND

Atomic Intrinsic Subroutine (Generic): *Performs atomic fetch and bitwise AND.*

Syntax

```
CALL ATOMIC_FETCH_AND (atom, value, old [, stat])
```

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `iand` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
old	(Output) Must be a scalar of the same type as *atom*. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value *atom* has at the beginning of the atomic operation.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_FETCH_AND (N[4], 29, M)
```

If the value of N on image 4 was 23 when the atomic operation is initiated, N on image 4 is defined with the value 21, and M is defined with the value 23 when the operation completes and no error occurs during the subroutine reference.

ATOMIC_FETCH_OR

Atomic Intrinsic Subroutine (Generic): *Performs atomic fetch and bitwise OR.*

Syntax

`CALL ATOMIC_FETCH_OR (`*atom*`, `*value*`, `*old*` [, `*stat*`])`

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `ior` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
old	(Output) Must be a scalar of the same type as *atom*. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value *atom* has at the beginning of the atomic operation.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
ATOMIC_FETCH_OR (N[4], 9, M)
```

If the value of N on image 4 is 4 when the atomic operation is initiated, N on image 4 is defined with the value 13, and M is defined with the value 4 when the operation completes and no error occurs during the subroutine reference.

ATOMIC_FETCH_XOR

Atomic Intrinsic Subroutine (Generic): *Performs atomic fetch and bitwise exclusive OR.*

Syntax

`CALL ATOMIC_FETCH_XOR (atom, value, old [, stat])`

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `ieor` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
old	(Output) Must be a scalar of the same type as *atom*. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value *atom* has at the beginning of the atomic operation.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_FETCH_XOR (N[4], 9, M)
```

If the value of N on image 4 was 10 when the atomic operation is initiated, N on image 4 is defined with the value 3, and M is defined with the value 10 when the operation completes and no error occurs during the subroutine reference.

ATOMIC_OR

Atomic Intrinsic Subroutine (Generic): *Performs atomic bitwise OR.*

Syntax

`CALL ATOMIC_OR (atom, value [, stat])`

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `ior` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_OR (N[4], 10)
```

If the value of N on image 4 is 9 when the atomic operation is initiated, the value of N on image 4 is 11 when the operation completes and no error condition occurs during the subroutine reference.

ISO_FORTRAN_ENV Module

ATOMIC_REF

Atomic Intrinsic Subroutine (Generic): *Lets you reference a variable atomically.*

Syntax

`CALL ATOMIC_REF (value, atom [, stat])`

value	(Output) Must be a scalar and of the same type as *atom*. If its kind is the same as that of *atom* or its type is logical, it becomes defined with the value of *atom*. Otherwise, it is defined with the value of INT(ATOM, KIND (VALUE)).
atom	(Input) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND. ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.

stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_REF (SOL, I [9])
```

This causes SOL to become defined with the value of I on image 9.

ATOMIC_XOR

Atomic Intrinsic Subroutine (Generic): *Performs atomic bitwise exclusive OR.*

Syntax

`CALL ATOMIC_XOR (atom, value [, stat])`

atom	(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `ieor` (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined. ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.
value	(Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

Example

Consider the following:

```
CALL ATOMIC_XOR (N[4], 10)
```

If the value of N on image 4 is 14 when the atomic operation is initiated, the value on N on image 4 is the value 4 when the operation is complete and no error condition occurred during the subroutine reference.

ATTRIBUTES

General Compiler Directive: *Declares properties for specified variables.*

Syntax

```
!DIR$ ATTRIBUTES att[,att]...:: object[,object]...
```

att

Is one of the following options (or properties):

ALIAS	DLLEXPORT	OPTIMIZATION_PARAMETER
ALIGN	DLLIMPORT	REFERENCE
ALLOCATABLE	EXTERN	STDCALL
ALLOW_NULL	FORCEINLINE	VALUE
C	IGNORE_LOC	VARYING
CODE_ALIGN	INLINE	VECTOR
CONCURRENCY_SAFE	MIXED_STR_LEN_ARG	
CVF	NO_ARG_CHECK	
DECORATE	NOCLONE	
DEFAULT	NOINLINE	

object

Is the name of a data object or procedure.

The following table shows which ATTRIBUTES options can be used with various objects:

Option	Variable and Array Declarations	Common Block Names [1]	Subprogram Specification and EXTERNAL Statements
ALIAS	No	Yes	Yes
ALIGN	Yes	No	No
ALLOCATABLE	Yes[2]	No	No
ALLOW_NULL	Yes	No	No
C	No	Yes	Yes
CODE_ALIGN	No	No	Yes[5, 6]
CONCURRENCY_SAFE	No	No	Yes
CVF	No	Yes	Yes
DECORATE	No	No	Yes
DEFAULT	No	Yes	Yes
DLLEXPORT	Yes[3]	Yes	Yes
DLLIMPORT	Yes	Yes	Yes
EXTERN	Yes	No	No

Option	Variable and Array Declarations	Common Block Names [1]	Subprogram Specification and EXTERNAL Statements
FASTMEM	Yes	No	No
FORCEINLINE	No	No	Yes
IGNORE_LOC	Yes[4]	No	No
INLINE	No	No	Yes
MIXED_STR_LEN_ARG	No	No	Yes
NO_ARG_CHECK	Yes	No	Yes[5]
NOCLONE	No	No	Yes
NOINLINE	No	No	Yes
OPTIMIZATION_PARAMETER	No	No	Yes[5, 6]
REFERENCE	Yes	No	Yes
STDCALL	No	Yes	Yes
VALUE	Yes	No	No
VARYING	No	No	Yes
VECTOR	No	No	Yes[5]

[1]A common block name is specified as [/]common-block-name[/]

[2]This option can only be applied to arrays.

[3]Module-level variables and arrays only.

[4]This option can only be applied to INTERFACE blocks.

[5]This option cannot be applied to EXTERNAL statements.

[6]This option can be applied to named main programs.

These options can be used in function and subroutine definitions, in type declarations, and with the INTERFACE and ENTRY statements.

Options applied to entities available through use or host association are in effect during the association. For example, consider the following:

```
MODULE MOD1
  INTERFACE
    SUBROUTINE NEW_SUB
    !DIR$ ATTRIBUTES C, ALIAS:'othername' :: NEW_SUB
    END SUBROUTINE
  END INTERFACE
  CONTAINS
    SUBROUTINE SUB2
    CALL NEW_SUB
    END SUBROUTINE
END MODULE
```

In this case, the call to NEW_SUB within SUB2 uses the C and ALIAS options specified in the interface block.

Options C, STDCALL, REFERENCE, VALUE, and VARYING affect the calling conventions of routines:

- You can specify C, STDCALL, REFERENCE, and VARYING for an entire routine.
- You can specify VALUE and REFERENCE for individual arguments.

Examples

```
INTERFACE
   SUBROUTINE For_Sub (I)
     !DIR$ ATTRIBUTES C, ALIAS:'_For_Sub' :: For_Sub
     INTEGER I
   END SUBROUTINE For_Sub
END INTERFACE
```

You can assign more than one option to multiple variables with the same compiler directive. All assigned options apply to all specified variables. For example:

```
!DIR$ ATTRIBUTES REFERENCE, VARYING, C :: A, B, C
```

In this case, the variables `A`, `B`, and `C` are assigned the REFERENCE, VARYING, and C options. The only restriction on the number of options and variables is that the entire compiler directive must fit on one line.

The identifier of the variable or procedure that is assigned one or more options must be a simple name. It cannot include initialization or array dimensions. For example, the following is not allowed:

```
!DIR$ ATTRIBUTES C :: A(10)  ! This is illegal.
```

The following shows another example:

```
SUBROUTINE ARRAYTEST(arr)
!DIR$ ATTRIBUTES DLLEXPORT :: ARRAYTEST
   REAL(4) arr(3, 7)
   INTEGER i, j
   DO i = 1, 3
     DO j = 1, 7
       arr (i, j) = 11.0 * i + j
     END DO
   END DO
END SUBROUTINE
```

Syntax Rules for Compiler Directives
Programming with Mixed Languages

ATTRIBUTES ALIAS

The ATTRIBUTES directive option ALIAS specifies an alternate external name to be used when referring to external subprograms.

Syntax

`!DIR$ ATTRIBUTES ALIAS: external-name:: subprogram`

external-name	Is a character constant delimited by apostrophes or quotation marks. The character constant is used as is; the string is not changed to uppercase, nor are blanks removed.
subprogram	Is an external subprogram.

The ALIAS option overrides the C (and STDCALL) option. If both C and ALIAS are specified for a subprogram, the subprogram is given the C calling convention, but not the C naming convention. It instead receives the name given for ALIAS, with no modifications.

ALIAS cannot be used with internal procedures, and it cannot be applied to dummy arguments.

The following example gives the subroutine happy the name "_OtherName@4" outside this scoping unit:

```
INTERFACE
  SUBROUTINE happy(i)
    !DIR$ ATTRIBUTES STDCALL, DECORATE, ALIAS:'OtherName' :: happy
    INTEGER i
  END SUBROUTINE
END INTERFACE
```

!DIR$ ATTRIBUTES ALIAS has the same effect as the !DIR$ ALIAS directive.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES DECORATE

ATTRIBUTES ALIGN

The ATTRIBUTES directive option ALIGN specifies the byte alignment for variables and for allocatable or pointer components of derived types.

Syntax

```
!DIR$ ATTRIBUTES ALIGN: n:: object
```

n	Is the number of bytes for the minimum alignment boundary. For allocatable *object*s, the boundary value must be a power of 2, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. *n* must have a value between 1 and 2097152 == 2**21 == 2MB on Linux* systems, and between 1 and 8192 == 2**13 == 8KB on Windows* systems. For non-allocatable *object*s, the boundary value must be a power of 2 between 1 and 64 on Windows systems, between 1 and 65536 == 2**16 == 64KB on Linux systems.
object	Is the variable or the allocatable or pointer component of a derived type to be aligned.

Objects that can be aligned by this directive include static local variables, automatic variables, module variables, dynamically allocated arrays, allocatable array components of derived types, and the start of common blocks. This directive cannot be used to align variables within common blocks

If you specify directive !DIR$ ATTRIBUTES ALIGN on an object with the ALLOCATABLE or POINTER attribute, an ALLOCATE statement will attempt to use that alignment when the memory is allocated.

For allocatable or pointer components of derived types, the directive must appear within the derived-type TYPE…END TYPE block.

If the TYPE is an extended type, the directive cannot reference a component in the parent type.

Example

Consider the following:

```
TYPE EXAMPLE
!DIR$ ATTRIBUTES ALIGN : 64 :: R_alloc
REAL, ALLOCATABLE :: R_alloc ( : )
REAL :: R_scalar
INTEGER :: I_nonalloc(25)
END TYPE EXAMPLE

TYPE (EXAMPLE) :: MyVar

ALLOCATE (MyVar%R_alloc(1000))   ! Memory is allocated aligned at a 64-byte boundary
```

Note that it is valid to give the ALIGN:64 attribute to component R_alloc, but not to component R_scalar or to component I_nonalloc.

The following example shows that the name of a common block may optionally be enclosed in slashes:

```
!DIR$ ATTRIBUTES ALIGN: n :: /common_name/
```

See Also

ATTRIBUTES

`align` compiler option (see setting array*n*byte)
Syntax Rules for Compiler Directives

ATTRIBUTES ALLOCATABLE

The ATTRIBUTES directive option ALLOCATABLE is provided for compatibility with older programs. It lets you delay allocation of storage for a particular declared entity until some point at runtime when you explicitly call a routine that dynamically allocates storage for the entity. Dummy arguments that have the ALLOCATABLE attribute should not also have the VALUE attribute.

Syntax

`!DIR$ ATTRIBUTES ALLOCATABLE :: entity`

entity	Is the name of the entity that should have allocation delayed.

The recommended method for dynamically allocating storage is to use the ALLOCATABLE statement or attribute.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES ALLOW_NULL

The ATTRIBUTES directive option ALLOW_NULL enables a corresponding dummy argument to pass a NULL pointer (defined by a zero or the NULL intrinsic) by value for the argument.

Syntax

`!DIR$ ATTRIBUTES ALLOW_NULL :: arg`

arg Is the name of the argument.

ALLOW_NULL is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES C and STDCALL

The ATTRIBUTES directive options C and STDCALL specify procedure calling, naming, and argument passing conventions.

Syntax

```
!DIR$ ATTRIBUTES C :: object[, object] ...
!DIR$ ATTRIBUTES STDCALL :: object[, object] ...
```

object Is the name of a data object or procedure.

On Windows* systems on IA-32 architecture, C and STDCALL have slightly different meanings; on all other platforms, STDCALL is treated as C.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions. The effects depend on whether or not the subprogram is interoperable (has the BIND attribute).

For interoperable subprograms with the BIND attribute, ATTRIBUTES STDCALL has the following effects for subprograms in applications targeting Windows systems on IA-32 architecture:

- The STDCALL calling convention is used where the called subprogram cleans up the stack at exit.
- The external name has @*n* appended, where *n* is the number of bytes of arguments pushed on the stack.

No other effects of ATTRIBUTES STDCALL are applied for interoperable subprograms. If pass-by-value is desired for a dummy argument to an interoperable subprogram, the Fortran standard VALUE attribute should be specified for that argument.

For platforms other than Windows systems on IA-32 architecture, ATTRIBUTES STDCALL has no effect on interoperable subprograms. You should not specify ATTRIBUTES C for interoperable subprograms.

The following table and subsequent text summarizes the differences between the calling conventions for subprograms that are not interoperable:

Convention	C [1]	STDCALL [1]	Default [2]
Arguments passed by value	Yes	Yes	No
Case of external subprogram names	Linux: Lowercase Windows: Lowercase	Linux: Lowercase Windows: Lowercase	Linux: Lowercase Windows: Uppercase
Linux only:			
Trailing underscore added	No	No	Yes[3]
Windows only:			
Leading underscore added	Yes	Yes	Yes[4]

Convention	C [1]	STDCALL [1]	Default [2]
Number of argument bytes added to name	No	Yes	No
Caller stack cleanup	Yes	No	Yes
Variable number of arguments	Yes	No	Yes

[1]STDCALL is treated as C on Linux*, and on Windows* on Intel® 64 architecture.

[2]The Intel® Fortran calling convention

[3]On Linux, if there are one or more underscores in the external name, two trailing underscores are added; if there are no underscores, one is added.

[4]IA-32 architecture only

If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore (_) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:

- By default, hidden lengths are put at the end of the argument list.

  On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.
- If C or STDCALL (only) is specified:

  On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).
- If C or STDCALL is specified, and REFERENCE is specified for the argument:

  On all systems, the string is passed with no length.
- If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is *not* specified for the argument, if any):

  On all systems, the string is passed with the length.

Compiler Reference section: *Mixed Language Programming*

ATTRIBUTES CODE_ALIGN

The ATTRIBUTES directive option CODE_ALIGN specifies the byte alignment for a procedure.

Syntax

```
!DIR$ ATTRIBUTES CODE_ALIGN: n:: procedure-name
```

n	Is the number of bytes for the minimum alignment boundary. It must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. If you specify 1 for *n*, no alignment is performed. If you do not specify *n*, the default alignment is 16 bytes.
procedure-name	Is the name of a procedure.

This directive can be affected by compiler option `-falign-loops` (Linux*) or `/Qalign-loops` (Windows*), the CODE_ALIGN directive, and the CODE_ALIGN attribute.

If code is compiled with the `-falign-loops=m` (Linux) or `/Qalign-loops:m` (Windows) option and a procedure has the CODE_ALIGN:k attribute, the procedure is aligned on a MAX (m, k) byte boundary. If a procedure has the CODE_ALIGN:k attribute and a CODE_ALIGN:n directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

Example

Consider the following code fragment in file `test_align.f90`:

```
FUNCTION F ()
!DIR$ ATTRIBUTES CODE_ALIGN:32 :: F
…
!DIR$ CODE_ALIGN:16
DO J = 1, N
…
END DO
…
END FUNCTION F
```

Compiling `test_align.f90` with option `-falign-loops=64` (Linux) or `/Qalign-loops:64` (Windows) aligns the function F and the DO J loop on 64-byte boundaries.

ATTRIBUTES CONCURRENCY_SAFE

The ATTRIBUTES directive option CONCURRENCY_SAFE specifies that there are no unacceptable side effects and no illegal (or improperly synchronized) memory access interferences among multiple invocations of a routine or between an invocation of the specified routine and other statements in the program if they were executed concurrently.

Syntax

`!DIR$ ATTRIBUTES CONCURRENCY_SAFE [: clause] :: routine-name-list`

clause	Is one of the following: • `profitable` • `cost` (*int-cycle-count*)

int-cycle-count	Is an integer scalar constant expression.
routine-name-list	Is a comma-separated list of function and subroutine names.

When a CONCURRENCY_SAFE routine is called from parallelized code, you can ignore assumed cross-block or cross-iteration dependencies and side effects of calling the specified routine from parallelized code.

The `profitable` clause indicates that the loops or blocks that contain calls to the routine can be safely executed in parallel if the loop or blocks are legal to be parallelized; that is, if it is profitable to parallelize them.

The `cost` clause indicates the execution cycles of the routine where the compiler can perform parallelization profitability analysis while compiling its enclosing loops or blocks.

The attribute can appear in the declaration of the routine; for example:

```
function f(x)
!DIR$ attributes concurrency_safe :: f
```

The attribute can also appear in the code of the caller; for example:

```
main m
integer f
external f
!dir$ attributes concurrency_safe :: f   ! or it could be in an interface block describing f
...
Print *, f(x)
```

NOTE
For every routine named in *routine-name-list*, you should ensure that any possible side effects are acceptable or expected, and the memory access interferences are properly synchronized.

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES CVF
The ATTRIBUTES direction option CVF tells the compiler to use calling conventions compatible with Compaq Visual Fortran and Microsoft Fortran PowerStation.*

Syntax

```
!DIR$ ATTRIBUTES CVF :: object[, object] ...
```

object	Is the name of a data object or procedure.

The conventions that are used are as follows:

- The calling mechanism: STDCALL on Windows* systems using IA-32 architecture
- The argument passing mechanism: by reference
- Character-length argument passing: following the argument address
- The external name case: uppercase
- The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where *n* is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES DECORATE

The ATTRIBUTES directive option DECORATE specifies that the external name used in !DIR$ ALIAS or !DIR$ ATTRIBUTES ALIAS should have the prefix and postfix decorations performed on it that are associated with the platform and calling mechanism that is in effect.

Syntax

```
!DIR$ ATTRIBUTES DECORATE :: exname
```

exname	Is an external name. It may not be the name of an internal procedure.

The case of the ALIAS external name is not modified.

If ALIAS is not specified, this option has no effect.

These are the same decorations performed on the procedure name when ALIAS is not specified, except that, on Linux* systems, DECORATE does not add a trailing underscore signifying a Fortran procedure.

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES ALIAS

The summary of prefix and postfix decorations in the description of the ATTRIBUTES options C and STDCALL

ATTRIBUTES DEFAULT

The ATTRIBUTES directive option DEFAULT overrides certain compiler options that can affect external routine and COMMON block declarations.

Syntax

```
c!DIR$ ATTRIBUTES DEFAULT :: entity
```

entity	Is an external procedure, a COMMON block, a module variable that is initialized, or a PARAMETER in a module.

It specifies that the compiler should ignore compiler options that change the default conventions for external symbol naming and argument passing for routines and COMMON blocks (such as names, assume underscore, assume 2underscores on Linux systems, and iface on Windows* systems).

This option can be combined with other ATTRIBUTES options, such as STDCALL, C, REFERENCE, ALIAS, etc. to specify properties different from the compiler defaults.

This option is useful when declaring INTERFACE blocks for external routines, since it prevents compiler options from changing calling or naming conventions.

assume compiler option

ATTRIBUTES DLLEXPORT and DLLIMPORT

The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library's interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. These directive options are available on Windows systems.*

Syntax

```
!DIR$ ATTRIBUTES DLLEXPORT :: object[, object] ...
!DIR$ ATTRIBUTES DLLIMPORT :: object[, object] ...
```

object	Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.

DLLEXPORT and DLLIMPORT define the interface for the following dynamic-link libraries:

- DLL on Windows*

DLLEXPORT specifies that procedures or data are being exported to other applications or dynamic libraries. This causes the compiler to produce efficient code; for example, eliminating the need on Windows systems for a module definition (.def) file to export symbols.

DLLEXPORT should be specified in the routine to which it applies. If the routine's implementation is in a submodule, specify DLLEXPORT in the parent module's INTERFACE block for the routine. If MODULE PROCEDURE is used in the submodule, the DLLEXPORT attribute will be inherited; otherwise you must also specify DLLEXPORT in the submodule routine.

Symbols defined in a DLL are imported by programs that use them. On Windows*, the program must link with the DLL import library (.lib).

The DLLIMPORT option is used inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES EXTERN

The ATTRIBUTES directive option EXTERN specifies that a variable is allocated in another source file. EXTERN can be used in global variable declarations, but it must not be applied to dummy arguments.

Syntax

```
!DIR$ ATTRIBUTES EXTERN :: var
```

var	Is the variable to be allocated.

This option must be used when accessing variables declared in other languages.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE

The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

Syntax

The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

```
!DIR$ ATTRIBUTES INLINE :: procedure
```

procedure Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function.

```
!DIR$ ATTRIBUTES NOINLINE :: procedure
```

procedure Is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors.

```
!DIR$ ATTRIBUTES FORCEINLINE :: procedure
```

procedure Is the function or subroutine that must be inlined.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES IGNORE_LOC

The ATTRIBUTES directive option IGNORE_LOC enables %LOC to be stripped from an argument.

Syntax

```
!DIR$ ATTRIBUTES IGNORE_LOC :: arg
```

arg Is the name of an argument.

IGNORE_LOC is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also

ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG

These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed.
MIXED_STR_LEN_ARG specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list.
NOMIXED_STR_LEN_ARG specifies that these hidden lengths should be placed in sequential order at the end of the argument list.

Syntax

```
!DIR$ ATTRIBUTES MIXED_STR_LEN_ARG :: procs
```

```
!DIR$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: procs
```

procs Is a list of procedures to be given the specified attribute.

The default is NOMIXED_STR_LEN_ARG. However, If you specify compiler option `/iface:CVF` or `/iface:mixed_str_len_arg` (Windows*), or compiler option `-mixed-str-len-arg` (Linux*), the default is MIXED_STR_LEN_ARG.

See Also

ATTRIBUTES directive
Syntax Rules for Compiler Directives
iface compiler option

ATTRIBUTES NO_ARG_CHECK

The ATTRIBUTES directive option NO_ARG_CHECK specifies that type and shape matching rules related to explicit interfaces are to be ignored. This permits the construction of an INTERFACE block for an external procedure or a module procedure that accepts an argument of any type or shape; for example, a memory copying routine.

Syntax

```
!DIR$ ATTRIBUTES NO_ARG_CHECK :: object
```

object Is the name of an argument or procedure.

NO_ARG_CHECK can appear only in an INTERFACE block for a non-generic procedure or in a module procedure. It can be applied to an individual dummy argument name or to the routine name, in which case the option is applied to all dummy arguments in that interface.

NO_ARG_CHECK *cannot* be used for procedures with the PURE or ELEMENTAL prefix.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES NOCLONE

The ATTRIBUTES directive option NOCLONE can be used to prevent a procedure from being considered for cloning, which is a mechanism performed by interprocedural constant propagation that produces specialized copies of the procedure.

Syntax

```
!DIR$ ATTRIBUTES NOCLONE :: procedure
```

procedure Is a function or subroutine that can be inlined.

Note that if you specify ATTRIBUTES NOINLINE, it does not prevent this cloning.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES INLINE

ATTRIBUTES OPTIMIZATION_PARAMETER
The ATTRIBUTES directive option OPTIMIZATION_PARAMETER passes certain information about a procedure or main program to the optimizer.

Syntax

`!DIR$ ATTRIBUTES OPTIMIZATION_PARAMETER: string::{ procedure-name | named-main-program}`

string

Is a character constant that is passed to the optimizer. The constant must be delimited by apostrophes or quotation marks, and it may have one of the following values:

- `TARGET_ARCH=` *cpu*

  Tells the compiler to generate code specialized for a particular processor. For the list of *cpu*s you can specify, see option `[Q]x`.
- `G2S` = {ON | OFF}

  Disables or enables the use of gather/scatter instructions in the specified program unit.

  ON tells the optimizer to disable the generation of gather/scatter and to transform gather/scatter into unit-strided loads/stores plus a set of shuffles wherever possible.

  OFF tells the optimizer to enable the generation of gather/scatter instructions and not to transform gather/scatter into unit-strided loads/stores.
- `INLINE_MAX_PER_ROUTINE=` *n*

  Specifies the maximum number of times the inliner may inline into the procedure. The *n* is one of the following:

  - A non-negative scalar integer constant (>=0) that specifies the maximum number of times the the inliner may inline into the procedure. If you specify zero, no inlining is done into the routine.
  - The keyword UNLIMITED, which means that there is no limit to the number of times the inliner may inline into the procedure.

  For more information, see option `[Q]inline-max-per-routine`.
- `INLINE_MAX_TOTAL_SIZE=` *n*

  Specifies how much larger a routine can normally grow when inline expansion is performed. The *n* is one of the following:

  - A non-negative scalar integer constant (>=0) that specifies the permitted increase in the routine's size when inline expansion is performed. If you specify zero, no inlining is done into the routine.
  - The keyword UNLIMITED, which means that there is no limit to the size a routine may grow when inline expansion is performed.

  For more information, see option `[Q]inline-max-total-size`.

procedure-name

Is the name of a procedure.

named-main-program Is the name of a main program

Description

The characters in string can appear in any combination of uppercase and lowercase. The following rules also apply to string:

- If string does not contain an equal sign (=), then the entire value of string is converted to lowercase before being passed to the optimizer.
- If string contains an equal sign, then all characters to the left of the equal sign are converted to lowercase before all of string is passed to the optimizer.

  Characters to the right of the equal sign are not converted to lowercase since their value may be case sensitive to the optimizer, for example "target_arch=AVX".

You can specify multiple ATTRIBUTES OPTIMIZATION_PARAMETER directives for one procedure or one main program.

For the named procedure or main program, the values specified for ATTRIBUTES OPTIMIZATION_PARAMETER override any settings specified for the following compiler options:

- `[Q]x`, `-m`, and `/arch`
- `[Q]inline-max-per-routine`
- `[Q]inline-max-total-size`

Example

Consider the two attributes optimization_parameter directives in the following code:

```
function f (x)
!dir$ attributes optimization_parameter: "inline_max_per_routine=10" :: f
!dir$ attributes optimization_parameter: "inline_max_total_size=2000" :: f
real :: f, x
…
```

The two directives have the same effect as if the function F had been complied with "`/Qinline-max-per-routine:10 /Qinline-max-total-size:2000`" on Windows* or with "`-inline-max-per-routine=10 -inline-max-total-size=2000`" on Linux*, that is, inlining will not increase the size of F by more than 2000 and the inliner will not inline routines into F more than 10 times.

Syntax Rules for Compiler Directives

`x, Qx` compiler option

`inline-max-per-routine, Qinline-max-per-routine` compiler option

`inline-max-total-size, Qinline-max-total-size` compiler option

ATTRIBUTES REFERENCE and VALUE

The ATTRIBUTES directive options REFERENCE and VALUE specify how a dummy argument is to be passed.

Syntax

`!DIR$ ATTRIBUTES REFERENCE :: arg`

`!DIR$ ATTRIBUTES VALUE :: arg`

arg Is the name of a dummy argument.

REFERENCE specifies a dummy argument's memory location is to be passed instead of the argument's value. VALUE should not be specified for a dummy argument that is ALLOCATABLE.

VALUE specifies a dummy argument's value is to be passed instead of the argument's memory location.

When VALUE is specified for a dummy argument, the actual argument passed to it can be of a different type. If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, *two* floating-point arguments (one containing the real part, the other containing the imaginary part) are passed by immediate value.

Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by value.

If REFERENCE (only) is specified for a character argument, the string is passed with no length.

If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified for the routine, the string is passed with no length. This is true even if REFERENCE is also specified for the routine.

If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has *not* been specified for the argument, the string is passed with the length.

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.

In the following example integer x is passed by value:

```
      SUBROUTINE Subr (x)
      INTEGER x
!DIR$ ATTRIBUTES VALUE :: x
```

C and STDCALL
ATTRIBUTES
Syntax Rules for Compiler Directives

Mixed Language Programming: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES VARYING
The ATTRIBUTES directive option VARYING allows a Fortran routine to call a C/C++ routine with a variable number of arguments.

Syntax

```
!DIR$ ATTRIBUTES VARYING :: var[, var] ...
```

var	Is a variable representing a C/C++ routine that takes a variable number of arguments.

This attribute can be used in an interface block to create an explicit interface for a C/C++ routine or it can be used on a variable declared EXTERN that represents a C/C++ routine. When the routine is called from the Fortran code, a variable number of arguments can be specified.

This attribute cannot be used with a Fortran routine declaration.

If ATTRIBUTES VARYING is specified, the C calling convention must also be used, either implicitly or explicitly.

All actual arguments in the routine call are passed to the called routine, regardless of the number of dummy arguments specified in the interface. If the called routine tries to access a dummy argument that has no matching actual argument, it causes a user error and the program may fail unpredictably.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES VECTOR

The ATTRIBUTES directive option VECTOR tells the compiler to vectorize the specified function or subroutine.

Syntax

```
!DIR$ ATTRIBUTES [att,] VECTOR [:clause] [, att]... :: routine-name
!DIR$ ATTRIBUTES [att,] VECTOR :(clause [, clause]...) [, att] :: routine-name
```

att

Is an ATTRIBUTES directive option. For a list of possible directive options, see the description of argument *att* in ATTRIBUTES.

clause

Is one or more of the following optional clauses:

- `LINEAR` (*var*1:*step*1 [, *var*2:*step*2]...)

  var — Is a scalar variable that is a dummy argument in the specified routine.

  step — Is a compile-time positive, integer constant expression.

  Tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of *var*1 is incremented by *step*1, *var*2 is incremented by *step*2, and so on.

  If more than one *step* is specified for a particular *var*, a compile-time error occurs.

  Multiple LINEAR clauses are merged as a union.
- `[NO]MASK`

  Determines whether the compiler generates a masked vector version of the routine.
- PROCESSOR (cpuid)
- `UNIFORM` (*arg* [, *arg*]…)

  arg — Is a scalar variable that is a dummy argument in the specified routine.

  Tells the compiler that the values of the specified arguments can be broadcasted to all iterations as a performance optimization.

  Multiple UNIFORM clauses are merged as a union.
- `VECTORLENGTH` (*n*[, *n*]…)

  n — Is a vector length (VL). It must be an integer, scalar constant expression that is a power of 2; the value must be 2, 4, 8, 16, 32, or 64. If you specify more than one *n*, the compiler will choose the VL from the values specified.

  Tells the compiler that each routine invocation at the call site should execute the computation equivalent to n times the scalar function execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- `VECTORLENGTHFOR` (*data-type*)

  `data-type` Is one of the following intrinsic data types:

Data Type	Fortran Intrinsic Type
INTEGER	Default INTEGER
INTEGER(1)	INTEGER (KIND=1)
INTEGER(2)	INTEGER (KIND=2)
INTEGER(4)	INTEGER (KIND=4)
INTEGER(8)	INTEGER (KIND=8)
REAL	Default REAL
REAL(4)	REAL (KIND=4)
REAL(8)	REAL (KIND=8)
COMPLEX	Default COMPLEX
COMPLEX(4)	COMPLEX (KIND=4)
COMPLEX(8)	COMPLEX (KIND=8)

  Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution where *n* is computed from `size_of_vector_register/ sizeof(data_type)`.

  For example, VECTORLENGTHFOR (REAL (KIND=4)) results in *n*=4 for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and *n*=8 for AVX target (packed float operations available on 256-bit YMM registers). VECTORLENGTHFOR(INTEGER (KIND=4)) results in *n*=4 for SSE2 to AVX targets.

  The VECTORLENGTHFOR and VECTORLENGTH clauses are mutually exclusive. You cannot use the VECTORLENGTHFOR clause with the VECTORLENGTH clause, and vice versa.

  Multiple VECTORLENGTHFOR clauses cause a syntax error.

Without explicit VECTORLENGTH and VECTORLENGTHFOR clauses, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

routine-name Is the name of a routine (a function or subroutine). It must be the enclosing routine or the routine immediately following the directive.

If you specify more than one clause, they must be separated by commas and enclosed in parentheses.

When you specify the ATTRIBUTES VECTOR directive, the compiler provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. If you specify one or more clauses, they affect the data parallel semantics provided by the compiler.

If you specify the ATTRIBUTES VECTOR directive with no VECTORLENGTH clause, a default VECTORLENGTH is computed based on efficiency heuristics of the vectorizer and the following:

- The return type of the function, if the function has a return type.
- The data type of the first non-scalar argument (that is, the first argument that is specified in the scalar clause), if any.
- Default integer type, if neither of the above is supplied.

If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model.

If you specify the ATTRIBUTES VECTOR directive with no clause, the compiler will generate vector code based on compiler efficiency heuristics and whatever processor compiler options are specified.

The VECTOR attribute implies the C attribute, so that when you specify the VECTOR attribute on a routine, the C attribute is automatically also set on the same routine. This changes how the routine name is decorated and how arguments are passed.

NOTE
You should ensure that any possible side effects for the specified routine-name are acceptable or expected, and the memory access interferences are properly synchronized.

The Fortran Standard keyword ELEMENTAL specifies that a procedure written with scalar arguments can be extended to conforming array arguments by processing the array elements one at a time in any order. The ATTRIBUTES VECTOR directive tells the optimizer to produce versions of the procedure *routine-name* that execute with contiguous slices of the array arguments as defined by the VECTORLENGTH clause in an "elemental" fashion. *routine-name* does not need to be defined as ELEMENTAL to be given the VECTOR attribute.

The VECTOR attribute causes the compiler to generate a short vector form of the procedure, which can perform the procedure's operation on multiple elements of its array arguments in a single invocation. The short vector version may be able to perform multiple operations as fast as the regular implementation performs a single operation by using the vector instruction set in the CPU.

In addition, when invoked from an OMP construct, the compiler may assign different copies of the elemental procedures to different threads, executing them concurrently. The end result is that your data parallel operation executes on the CPU using both the parallelism available in the multiple cores and the parallelism available in the vector instruction set. If the short vector procedure is called inside a parallel loop or an auto-parallelized loop that is vectorized, you can achieve both vector-level and thread-level parallelism.

The INTENT(OUT) or INTENT(INOUT) attribute is not allowed for arguments of a procedure with the VECTOR attribute since the VECTOR attribute forces the procedure to receive its arguments by value.

The Intel C/C++ compiler built in function __intel_simd_lane() may be helpful in removing certain performance penalties caused by non-unit stride vector access. Consider the following:

```
interface
! returns a number between 0 and vectorlength - 1 that reflects the current "lane id" within the
SIMD vector
! __intel_simd_lane() will return zero if the loop is not vectorized
    function for_simd_lane () bind (C, name = "__intel_simd_lane")
        integer (kind=4) :: for_simd_lane
        !DEC$ attributes known_intrinsic, default :: for_simd_lane
    end function for_simd_lane
end interface
```

For more details, see the Intel C++ documentation.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Example

The ATTRIBUTES VECTOR directive must be accessible in the caller, either via an INTERFACE block or by USE association.

The following shows an example of an external function with an INTERFACE block:

```
!... function definition

  function f(x)
 !dir$ attributes vector :: f
  real :: f, x
...
 !  attribute vector explicit in calling procedure using an INTERFACE

interface
   function f(x)
  !dir$ attributes vector :: f
  real :: f, x
  end
end interface
...
do i=1,n
  z(i) = f( x(i) )
end do
```

The ATTRIBUTES VECTOR directive can be brought into the caller by USE association if the vector function is a module procedure; for example:

```
!  attribute vector in definition of module procedure

module use_vect

contains
```

```
  function f(x)
  !dir$ attributes vector :: f
    real :: f, x
...
  end function
end module use_vect

!  USE and call of f(x) from another procedure with a module USE statement

 USE use_vect     ! brings in ATTRIBUTE VECTOR for f(x)
...

! now simply call f(x)

do i=1,n
  z(i) = f( x(i) )
end do
```

You can specify more than one SCALAR or LINEAR clause in an ATTRIBUTES VECTOR directive. For example, all of the following are valid:

```
!DIR$ ATTRIBUTES VECTOR:PROCESSOR(atom) :: f
!DIR$ ATTRIBUTES VECTOR:(SCALAR(a), SCALAR(b)) :: f
!DIR$ ATTRIBUTES VECTOR:(LINEAR(x:1), LINEAR(y:1)) :: f
```

The three directives above are equivalent to specifying a single, continued, directive in fixed-form source, as follows:

```
!DIR$ ATTRIBUTES VECTOR:( PROCESSOR(atom),
!DIR$& SCALAR(a, b),
!DIR$& LINEAR(x:1, y:1) ) :: f
```

ATTRIBUTES

Syntax Rules for Compiler Directives

AUTOMATIC

Statement and Attribute: *Controls the storage allocation of variables in subprograms (as does STATIC). Variables declared as AUTOMATIC and allocated in memory reside in the stack storage area, rather than at a static memory location.*

Syntax

The AUTOMATIC attribute can be specified in a type declaration statement or an AUTOMATIC statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] AUTOMATIC [, *att-ls*] :: *v*[, *v*] ...

Statement:

AUTOMATIC [::] *v*[, *v*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.

v	Is the name of a variable or an array specification. It can be of any type.

AUTOMATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

Automatic variables can reduce memory use because only the variables currently being used are allocated to memory.

Automatic variables allow possible recursion. With recursion, a subprogram can call itself (directly or indirectly), and resulting values are available upon a subsequent call or return to the subprogram. For recursion to occur, RECURSIVE must be specified in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

By default, the compiler allocates local scalar variables on the stack. Other non-allocatable variables of non-recursive subprograms are allocated in static storage by default. This default can be changed through compiler options. Appropriate use of the SAVE attribute may be required if your program assumes that local variables retain their definition across subprogram calls.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE (in one of the ways mentioned above).

To override any compiler option that may affect variables, explicitly specify the variables as AUTOMATIC.

NOTE
Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as AUTOMATIC more than once in the same scoping unit.

If the variable is a pointer, AUTOMATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as AUTOMATIC. The following table shows these restrictions:

Variable	AUTOMATIC
Dummy argument	No
Automatic object	No
Common block item	No
Use-associated item	No
Function result	No
Component of a derived type	No

If a variable is in a module's outer scope, it *cannot* be specified as AUTOMATIC.

Use the `heap-arrays` compiler option to avoid stack overflows at runtime by placing large automatic arrays in the heap instead of on the stack.

Example

The following example shows a type declaration statement specifying the AUTOMATIC attribute:

```
REAL, AUTOMATIC :: A, B, C
```

The following example uses an AUTOMATIC statement:

```
...
CONTAINS
 INTEGER FUNCTION REDO_FUNC
   INTEGER I, J(10), K
   REAL C, D, E(30)
   AUTOMATIC I, J, K(20)
   STATIC C, D, E
   ...
 END FUNCTION
...
C       In this example, all variables within the program unit
C       are saved, except for "var1" and "var3". These are
C       explicitly declared in an AUTOMATIC statement, and thus have
C       memory locations on the stack:
        SUBROUTINE DoIt (arg1, arg2)
        INTEGER(4) arg1, arg2
        INTEGER(4) var1, var2, var3, var4
        SAVE
        AUTOMATIC var1, var3
C       var2 and var4 are saved
```

BACKSPACE

Statement: *Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing. It takes one of the following forms:*

Syntax

`BACKSPACE ([UNIT=]`*`io-unit`*`[, ERR=`*`label`*`] [, IOMSG=`*`msg-var`*`] [, IOSTAT=`*`i-var`*`])`

`BACKSPACE `*`io-unit`*

io-unit	(Input) Is an external unit specifier.
label	Is the label of the branch target statement that receives control if an error occurs.
msg-var	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The I/O unit number must specify an open file on disk or magnetic tape.

Backspacing from the current record *n* is performed by rewinding to the start of the file and then performing *n* - 1 successive READs to reach the previous record.

A BACKSPACE statement must not be specified for a file that is open for direct or append access, because *n* is not available to the Fortran I/O system.

BACKSPACE cannot be used to skip over records that have been written using list-directed or namelist formatting.

If a file is already positioned at the beginning of a file, a BACKSPACE statement has no effect.

If the file is positioned between the last record and the end-of-file record, BACKSPACE positions the file at the start of the last record.

Example

```
BACKSPACE 5
BACKSPACE (5)
BACKSPACE lunit
BACKSPACE (UNIT = lunit, ERR = 30, IOSTAT = ios)
```

The following statement repositions the file connected to I/O unit 4 back to the preceding record:

```
BACKSPACE 4
```

Consider the following statement:

```
BACKSPACE (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 back to the preceding record. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

Branch Specifiers

BADDRESS

Inquiry Intrinsic Function (Generic): *Returns the address of an argument. This function cannot be passed as an actual argument. This function can also be specified as IADDR.*

Syntax

```
result = BADDRESS (x)
```

x Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

Example

```
PROGRAM batest
  INTEGER X(5), I
  DO I=1, 5
    PRINT *, BADDRESS(X(I))
  END DO
END
```

BARRIER

OpenMP* Fortran Compiler Directive:
Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.

Syntax

```
!$OMP BARRIER
```

The binding thread set for a BARRIER construct is the current team. A barrier region binds to the innermost enclosing parallel region.

Each barrier region must be encountered by all threads in a team or by none at all, unless cancellation has been requested for the innermost enclosing parallel region.

The barrier region must also be encountered in the same order by all threads in a team.

Example

```
INTEGER K
K = 17

!$OMP PARALLEL SHARED (K) NUM_THREADS (2)
IF (OMP_GET_THREAD_NUM() == 0) THEN
    X = 5
ELSE
    ! The following read access of K creates a race condition
    PRINT *,"1: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ENDIF

! This barrier contains implicit flushes on all threads, as well as a thread
! synchronization: this guarantees that the value 5 will be printed by
! both PRINT 2 and PRINT 3 below.

!$OMP BARRIER

IF (OMP_GET_THREAD_NUM() == 0) THEN
    PRINT *,"2: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ELSE
    PRINT *,"3: THREAD# ", OMP_GET_THREAD_NUM (), "K = ", K
ENDIF
!$OMP END PARALLEL
```

BEEPQQ

Portability Subroutine: *Sounds the speaker at the specified frequency for the specified duration in milliseconds.*

Module

USE IFPORT

Syntax

```
CALL BEEPQQ (frequency,duration)
```

frequency	(Input) INTEGER(4). Frequency of the tone in Hz.
duration	(Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Example

```
USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration  = 1000
CALL BEEPQQ(frequency, duration)
```

See Also

SLEEPQQ

BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

Portability Functions: *Compute the single-precision values of Bessel functions of the first and second kinds.*

Module

USE IFPORT

Syntax

```
result = BESJ0 (value)
result = BESJ1 (value)
result = BESJN (n, value)
result = BESY0 (posvalue)
result = BESY1 (posvalue)
result = BESYN (n, value)
```

value	(Input) REAL(4). Independent variable for a Bessel function.

n	(Input) INTEGER(4). Specifies the order of the selected Bessel function computation.
posvalue	(Input) REAL(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results

BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and *n*, respectively, with the independent variable *posvalue*.

BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and *n*, respectively, with the independent variable *posvalue*.

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

DBESJ0, DBESJ1, DBESJN

BESSEL_J0

Elemental Intrinsic Function (Generic): *Computes a Bessel function of the first kind, order 0.*

Syntax

```
result = BESSEL_J0 (x)
```

x	(Input) Must be of type real.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order zero of *x*.

Example

BESSEL_J0 (1.0) has the approximate value 0.765.

BESSEL_J1

Elemental Intrinsic Function (Generic): *Computes a Bessel function of the first kind, order 1.*

Syntax

```
result = BESSEL_J1 (x)
```

x	(Input) Must be of type real.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order 1 of *x*.

Example

BESSEL_J1 (1.0) has the approximate value 0.440.

BESSEL_JN

Elemental and Transformational Intrinsic Functions (Generic): *Compute Bessel functions of the first kind.*

Syntax

```
Elemental function: result = BESSEL_JN (n, x)
```

```
Transformational function: result = BESSEL_JN (n1, n2, x)
```

n, *n1*, *n2* (Input) Must be of type integer and nonnegative.

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*.

The result of BESSEL_JN (*n*, *x*) is scalar. The result value of BESSEL_JN (*n* , *x*) is a processor-dependent approximation to the Bessel function of the first kind and order *n* of *x*.

The result of BESSEL_JN (*n1*, *n2*, *x*) is a rank-one array with extent MAX (*n2* - *n1* + 1, 0). Element *i* of the result value of BESSEL_JN (*n1*, *n2*, *x*) is a processor-dependent approximation to the Bessel function of the first kind and order *n1* + *i* - 1 of *x*.

Example

BESSEL_JN (2, 1.0) has the approximate value 0.115.

Consider the following program Bessel.90:

```
  real :: z (6) = [0:5]/5.          ! 0.0 through 1.0 by 0.2
  print *, z
  print *, bessel_jn (2, 1.0)      ! scalar argument, answer about 0.115
  print *, bessel_jn (1, z)          ! elemental
  print *, bessel_jn (1, 4, 1.0)  ! orders 1 thru 4 on a scalar
  end
```

Compile bessel.f90 and execute the result:

```
> ifx Bessel.f90 -o Bessel
> bessel
```

The above commands produce the following result:

```
 0.0000000E+00  0.2000000      0.4000000      0.6000000      0.8000000      1.000000
 0.1149035
 0.0000000E+00  9.9500835E-02  0.1960266      0.2867010      0.3688421      0.4400506
 0.4400506      0.1149035      1.9563355E-02  2.4766389E-03
```

BESSEL_Y0

Elemental Intrinsic Function (Generic): *Computes a Bessel function of the second kind, order 0.*

Syntax

```
result = BESSEL_Y0 (x)
```

x (Input) Must be of type real with a value greater than zero.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order zero of *x*.

Example

BESSEL_Y0 (1.0) has the approximate value 0.088.

BESSEL_Y1

Elemental Intrinsic Function (Generic): *Computes a Bessel function of the second kind, order 1.*

Syntax

```
result = BESSEL_Y1 (x)
```

x (Input) Must be of type real with a value greater than zero.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order 1 of *x*.

Example

BESSEL_Y1 (1.0) has the approximate value -0.781.

BESSEL_YN

Elemental and Transformational Intrinsic Functions (Generic): *Compute Bessel functions of the second kind.*

Syntax

```
Elemental function: result = BESSEL_YN (n, x)
Transformational function: result = BESSEL_YN (n1, n2, x)
```

n, *n1*, *n2* (Input) Must be of type integer and nonnegative.

x (Input) Must be of type real with a value greater than zero.

Results

The result type and kind are the same as *x*.

The result of BESSEL_YN (*n*, *x*) is scalar. The result value of BESSEL_YN (*n* , *x*) is a processor-dependent approximation to the Bessel function of the second kind and order *n* of *x*.

The result of BESSEL_YN (*n1*, *n2*, *x*) is a rank-one array with extent MAX (*n2* - *n1* + 1, 0). Element *i* of the result value of BESSEL_YN (*n1*, *n2*, *x*) is a processor-dependent approximation to the Bessel function of the second kind and order *n1* + *i* - 1 of *x*.

Example

BESSEL_YN (2, 1.0) has the approximate value -1.651.

BGE

Elemental Intrinsic Function (Generic): *Performs a bitwise greater than or equal to on its arguments.*

Syntax

```
result = BGE (i,j)
```

i	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results

The result is true if the sequence of bits represented by *i* is greater than or equal to the sequence of bits represented by *j*, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

If BIT_SIZE (J) has the value 8, BGE (Z'FF', J) has the value true for any value of J. BGE (0, -1) has the value false.

See Also

BIT_SIZE

BGT

Elemental Intrinsic Function (Generic): *Performs a bitwise greater than on its arguments.*

Syntax

```
result = BGT (i,j)
```

i	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results

The result is true if the sequence of bits represented by *i* is greater than the sequence of bits represented by *j*, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

BGT (Z'FF', Z'FC') has the value true. BGT (0, -2) has the value false.

BIC, BIS

Portability Subroutines: *Perform a bit-level set and clear for integers.*

Module

USE IFPORT

Syntax

`CALL BIC (bitnum, target)`

`CALL BIS (bitnum, target)`

bitnum	(Input) INTEGER(4). Bit number to set. Must be in the range 0 (least significant bit) to 31 (most significant bit) if *target* is INTEGER(4). If *target* is INTEGER(8), *bitnum* must be in range 0 to 63.
target	(Input) INTEGER(4) or INTEGER(8). Variable whose bit is to be set.

BIC sets bit *bitnum* of *target* to 0; BIS sets bit *bitnum* to 1.

Example

Consider the following:

```
USE IFPORT
 integer(4) bitnum, target_i4
 integer(8) target_i8
 target_i4 = Z'AAAA'
 bitnum = 1
 call BIC(bitnum, target_i4)
 target_i8 = Z'FFFFFFFF00000000'
 bitnum = 40
 call BIC(bitnum, target_i8)
 bitnum = 0
 call BIS(bitnum, target_i4)
 bitnum = 1
 call BIS(bitnum, target_i8)
 print '(" integer*4 result ",Z)', target_i4
 print '(" integer*8 result ",Z)', target_i8
 end
```

BIT

BIND

Statement and Attribute: *Specifies that an object is interoperable with C and has external linkage.*

Syntax

The BIND attribute can be specified in a type declaration statement or a BIND statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] BIND (C [, NAME=*ext-name*]) [, *att-ls*] :: *object*

Statement:

BIND (C [, NAME=*ext-name*]) [::] *object*

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
ext-name	Is a character scalar constant expression that can be used to construct the external name.
object	Is the name of a variable or common block. It can also be the name of an internal procedure if NAME= is not specified.

Description

If a common block is specified in a BIND statement, it must be specified with the same binding label in each scoping unit in which it is declared.

For variables and common blocks, BIND also implies the SAVE attribute, which may be explicitly confirmed with SAVE.

A variable given the BIND attribute (or declared in a BIND statement) must appear in the specification part of a module. You cannot specify BIND for a subroutine local variable or a variable in a main program.

The BIND attribute is similar to directive !DIR$ ATTRIBUTES C as follows:

- The compiler applies the same naming rules, that is, names are lowercase (unless NAME= specifies otherwise).
- The compiler applies the appropriate platform decoration, such as a leading underscore.

However, procedure argument passing differs. When BIND is specified, procedure arguments are passed by reference unless the VALUE attribute is also specified. A dummy argument of a procedure with the BIND attribute cannot be given both the VALUE and the OPTIONAL attributes.

The BIND attribute can optionally be used in a PROCEDURE, SUBROUTINE, or FUNCTION declaration. It must be used in an ENUM declaration.

Example

The following example shows the BIND attribute used in a type declaration statement, a statement, and a SUBROUTINE statement.

```
INTEGER, BIND(C) :: SOMEVAR

BIND(C,NAME='SharedCommon') :: /SHAREDCOMMON/

! you need empty parens after the subroutine name if BIND is present
SUBROUTINE FOOBAR() BIND(C, NAME='FooBar')
...
END SUBROUTINE
```

BIT

Portability Function: *Performs a bit-level test for integers.*

Module

USE IFPORT

Syntax

`result = BIT (bitnum, source)`

bitnum	(Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).
source	(Input) INTEGER(4) or INTEGER(8). Variable being tested.

Results

The result type is logical. It is .TRUE. if bit *bitnum* of *source* is 1; otherwise, .FALSE..

See Also

BIC, BIS

BIT_SIZE

Inquiry Intrinsic Function (Generic): *Returns the number of bits in an integer type.*

Syntax

`result = BIT_SIZE (i)`

i	(Input) Must be of type integer or of type logical (which is treated as an integer).

Results

The result is a scalar integer with the same kind parameter as *i*. The result value is the number of bits (*s*) defined by the bit model for integers with the kind parameter of the argument. For information on the bit model, see Model for Bit Data.

Example

BIT_SIZE (1_2) has the value 16 because the KIND=2 integer type contains 16 bits.

BTEST

IBCLR
IBITS
IBSET

BLE

Elemental Intrinsic Function (Generic): *Performs a bitwise less than or equal to on its arguments.*

Syntax

```
result = BLE (i,j)
```

i	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results

The result is true if the sequence of bits represented by *i* is less than or equal to the sequence of bits represented by *j*, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

BLE (0, J) has the value true for any value of J. BLE (-2, 0) has the value false.

BLOCK

Statement: *Marks the beginning of a BLOCK construct. The BLOCK construct executes a block of statements or constructs that can contain declarations.*

Syntax

```
[name:] BLOCK
   [specification-part]
   block
END BLOCK [name]
```

name	(Optional) Is the name of the BLOCK construct.
specification-part	(Optional) Is one or more specification statements, except for the following: • COMMON • FUNCTION (outside of an INTERFACE block) • EQUIVALENCE • IMPLICIT

- INTENT (or its equivalent attribute)
- MODULE
- NAMELIST
- OPTIONAL (or its equivalent attribute)
- SUBROUTINE (outside of an INTERFACE block)
- VALUE (or its equivalent attribute)
- Statement functions

block

Is a sequence of zero or more statements or constructs, except for the following:

- CONTAINS (outside of a TYPE definition)
- ENTRY
- Statement functions

Description

A BLOCK construct is itself a scoping unit. Entities declared in a BLOCK construct are local to the BLOCK construct and are accessible only in that construct and in any contained constructs. A local entity in a block construct hides any entity with the same name in its host scope. No transfer of control into a block from outside the block is allowed, except for the return from a procedure call. Transfers within a block or out of the block are allowed.

If a construct name is specified at the beginning of a BLOCK statement, the same name must appear in the corresponding END BLOCK statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a BLOCK statement, you cannot specify one following the END BLOCK statement.

You can only branch to an END BLOCK statement from within its BLOCK construct.

The SAVE attribute specifies that a local variable of a BLOCK construct retains its association status, allocation status, definition status, and value after termination of the construct unless it is a pointer and its target becomes undefined. If the BLOCK construct contains a SAVE statement, the SAVE statement cannot specify the name of a common block. A SAVE statement outside a BLOCK construct does not affect variables local to the BLOCK construct, because a SAVE statement affects variables in its scoping unit which excludes nested scoping units in it.

The statements specified within the *specification-part* are evaluated in a processor-dependent order, followed by execution of block. When execution exits block, all non-SAVEd automatic and allocatable local variables are deallocated.

Example

The following shows a BLOCK construct:

```
block
  integer :: i
  real :: a(n)
   do i = 1,n
     a(i) = i
   end do
  …
end block
```

When control exits the bottom of the BLOCK, local variables `i` and `a` revert to their meaning outside the block.

The following example shows two nested BLOCK constructs where the inner BLOCK construct has the construct name INNER and the outer one does not have a name:

```
  BLOCK
    ...
    INNER: BLOCK
      ...
    END BLOCK INNER
    ...
  END BLOCK
```

In the following example, the appearance and the reference of the FORMAT statement are legal:

```
  PROGRAM MAIN
    WRITE(6, FMT=10)
    ...
    BLOCK
10    FORMAT("Hello")
    END BLOCK
    ...
  END
```

Implicit typing is not affected by BLOCK constructs. In the following example, even if NSQP only appears in the two BLOCK constructs, the scope of NSQP is the whole subroutine S:

```
  SUBROUTINE S(N)
    ...
    IF (N>0) THEN
      BLOCK
        NSQP = CEILING(SQRT(DBLE(N)))
      END BLOCK
    END IF
    ...
    IF (N>0) THEN
      BLOCK
        PRINT *,NSQP
      END BLOCK
    END IF
  END SUBROUTINE S
```

BLOCK DATA

Statement: *Identifies a block-data program unit, which provides initial values for variables in named common blocks. BLOCK DATA is an obsolescent language feature in Standard Fortran.*

Syntax

```
BLOCK DATA [name]
   [specification-part]
END [BLOCK DATA [name]]
```

name — Is the name of the block data program unit.

specification-part — Is one or more of the following statements:

COMMON	INTRINSIC	STATIC
DATA	PARAMETER	TARGET

Derived-type definition	POINTER	Type declaration [2]
DIMENSION	RECORD[1]	USE [3]
EQUIVALENCE	Record structure declaration[1]	
IMPLICIT	SAVE	

[1] For more information, see RECORD statement and record structure declarations.

[2] Can only contain attributes: DIMENSION, INTRINSIC, PARAMETER, POINTER, SAVE, STATIC, or TARGET.

[3] Allows access to only named constants.

Description

A block data program unit need not be named, but there can only be one unnamed block data program unit in an executable program.

If a name follows the END statement, it must be the same as the name specified in the BLOCK DATA statement.

An interface block must not appear in a block data program unit and a block data program unit must not contain any executable statements.

If a DATA statement initializes any variable in a named common block, the block data program unit must have a complete set of specification statements establishing the common block. However, all of the variables in the block do not have to be initialized.

A block data program unit can establish and define initial values for more than one common block, but a given common block can appear in only one block data program unit in an executable program.

The name of a block data program unit can appear in the EXTERNAL statement of a different program unit to force a search of object libraries for the block data program unit at link time.

Example

The following shows a block data program unit:

```
BLOCK DATA BLKDAT
  INTEGER S,X
  LOGICAL T,W
  DOUBLE PRECISION U
  DIMENSION R(3)
  COMMON /AREA1/R,S,U,T /AREA2/W,X,Y
  DATA R/1.0,2*2.0/, T/.FALSE./, U/0.214537D-7/, W/.TRUE./, Y/3.5/
END
```

The following shows another example:

```
C      Main Program
       CHARACTER(LEN=10) family
       INTEGER a, b, c, d, e
       REAL X(10), Y(4)
       COMMON/Lakes/a,b,c,d,e,family/Blk2/x,y
       ...
C      The following block-data subprogram initializes
C      the named common block /Lakes/:
```

```
C
       BLOCK DATA InitLakes
       COMMON /Lakes/ erie, huron, michigan, ontario,
      +        superior, fname
       DATA erie, huron, michigan, ontario, superior /1, 2, 3, 4, 5/
       CHARACTER(LEN=10) fname/'GreatLakes'/
       INTEGER erie, huron, michigan, ontario, superior
       END
```

BLOCK_LOOP and NOBLOCK_LOOP

General Compiler Directives: *Enables or disables loop blocking for the immediately following nested DO loops. BLOCK_LOOP enables loop blocking for the nested loops. NOBLOCK_LOOP disables loop blocking for the nested loops.*

Syntax

`!DIR$ BLOCK_LOOP [clause[[,] clause]...]`

`!DIR$ NOBLOCK_LOOP`

clause Is one or more of the following:

- `FACTOR`(*expr*)

  expr Is a positive scalar constant integer expression representing the blocking factor for the specified loops.

  This clause is optional. If the FACTOR clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the directive.

  At most only one FACTOR clause can appear in a BLOCK_LOOP directive.
- `LEVEL`(*level* [, *level*]...])

  level Is specified in the form:

  const1 or *const1*:*const2*

  where *const1* is a positive integer constant *m* <= 8 representing the loop at level *m*, where the immediate following loop is level 1.

The *const2* is a positive integer constant *n* <= 8 representing the loop at level *n*, where *n* > *m*: *const1*:*const2* represents the nested loops from level *const1* through *const2*.

This clause is optional. If the LEVEL clause is not present, the specified blocking factor is applied to all levels of the immediately following nested loops.

At most only one LEVEL clause can appear in a BLOCK_LOOP directive.

The clauses can be specified in any order. If you do not specify any *clause*, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.

The BLOCK_LOOP directive lets you exert greater control over optimizations on a specific DO loop inside a nested DO loop.

Using a technique called loop blocking, the BLOCK_LOOP directive separates large iteration counted DO loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no LEVEL and FACTOR clause, the blocking factor will be determined based on the processor's type and memory access patterns and it will apply to all the levels in the nested loops following this directive.

You can use the NOBLOCK_LOOP directive to tune the performance by disabling loop blocking for nested loops.

NOTE
The loop-carried dependence is ignored during the processing of BLOCK_LOOP directives.

Example

```
!dir$ block_loop factor(256) level(1)       ! applies blocking factor 256 to
!dir$ block_loop factor(512) level(2)       !  the top level loop in the following
                                            !  nested loop and blocking factor 512 to
                                            !  the 2nd level {1st nested} loop

!dir$ block_loop factor(256) level(2)
!dir$ block_loop factor(512) level(1)       ! levels can be specified in any order

!dir$ block_loop factor(256) level(1:2)     ! adjacent loops can be specified as a range

!dir$ block_loop factor (256)     ! the blocking factor applies to all levels of loop nest

!dir$ block_loop                  ! the blocking factor will be determined based on
                                  !  processor type and memory access patterns and will
                                  !  be applied to all the levels in the nested loop
                                  !  following the directive

!dir$ noblock_loop                ! None of the levels in the nested loop following this
                                  !  directive will have a blocking factor applied
```

Consider the following:

```
!dir$ block_loop factor(256) level(1:2)
do  j = 1,n
        f  = 0
       do  i =1,n
            f  =  f +   a (i) *  b (i)
        enddo
         c(j) = c(j) + f
enddo
```

The above code produces the following result after loop blocking:

```
do jj=1,n/256+1
   do ii = 1,n/256+1
        do j = (jj-1)*256+1, min(jj*256, n)
             f = 0
             do i = (ii-1)*256+1, min(ii*256,n)
                 f = f + a(i) * b(i)
              enddo
              c(j) = c(j) + f
         enddo
    enddo
enddo
```

BLT

Elemental Intrinsic Function (Generic): *Performs a bitwise less than on its arguments.*

Syntax

`result = BLT (i,j)`

i	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results

The result is true if the sequence of bits represented by *i* is less than the sequence of bits represented by *j*, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

BLT (0, 2) has the value true. BLT (Z'FF', Z'FC') has the value false.

BSEARCHQQ

Portability Function: *Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.*

Module

USE IFPORT

Syntax

`result = BSEARCHQQ (adrkey,adrarray,length,size)`

adrkey
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the variable containing the element to be found (returned by LOC).

adrarray
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

length
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in the array.

size
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in `IFPORT.F90`, specify type and kind for numeric arrays:

Constant	Type of array
SRT$INTEGER1	INTEGER(1)
SRT$INTEGER2	INTEGER(2) or equivalent
SRT$INTEGER4	INTEGER(4) or equivalent
SRT$INTEGER8	INTEGER(8) or equivalent
SRT$REAL4	REAL(4) or equivalent
SRT$REAL8	REAL(8) or equivalent
SRT$REAL16	REAL(16) or equivalent

If the value provided in *size* is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with *size* characters per element.

Results

The result type is INTEGER(4). It is an array index of the matched entry, or 0 if the entry is not found.

The array must be sorted in ascending order before being searched.

Caution
The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the *length* and *size* arguments are correct, and that *size* is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

Example

The following example shows a way to use BSEARCHQQ:

```
USE IFPORT
INTEGER(4) array(10)
INTEGER(4) result, target
INTEGER(8) length
length = SIZE(array)
do i = 1,length
array(i) = i
end do
target = 8
write(*,100)length,array,target
100 Format("Array length :: ",i8,/,"Array Elements :: ",10i5,/,"Target number :: ",i5)
result = BSEARCHQQ(LOC(target),LOC(array),length,SRT$INTEGER4)
write(*,101) result
101 Format("Location :: ",i4)
End
```

SORTQQ
LOC

BTEST

Elemental Intrinsic Function (Generic): *Tests a bit of an integer argument.*

Syntax

`result = BTEST (i,pos)`

i	(Input) Must be of type integer or of type logical (which is treated as an integer).
pos	(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(*i*). The rightmost (least significant) bit of *i* is in position 0.

Results

The result type is default logical.

The result is true if bit *pos* of *i* has the value 1. The result is false if *pos* has the value zero. For more information, see Bit Functions.

For information on the model for the interpretation of an integer value as a sequence of bits, see Model for Bit Data.

The setting of compiler options specifying integer size can affect this function.

Specific Name	Argument Type	Result Type
BBTEST	INTEGER(1)	LOGICAL(1)
BITEST[1]	INTEGER(2)	LOGICAL(2)
BTEST [2]	INTEGER(4)	LOGICAL(4)
BKTEST	INTEGER(8)	LOGICAL(8)

[1]Or HTEST

[2]Or BJTEST

Example

BTEST (9, 3) has the value true.

If A has the value

```
  [ 1   2 ]
  [ 3   4 ],
```

the value of BTEST (A, 2) is

```
  [ false  false ]
  [ false   true ]
```

and the value of BTEST (2, A) is

```
  [ true   false ]
  [ false  false ].
```

The following shows more examples:

Function reference	Value of *i*	Result
BTEST (*i*,2)	00011100 01111000	.FALSE.
BTEST (*i*,3)	00011100 01111000	.TRUE.

The following shows another example:

```
INTEGER(1) i(2)
LOGICAL result(2)
i(1) = 2#10101010
i(2) = 2#01010101
result = BTEST(i, (/3,2/))   ! returns (.TRUE.,.TRUE.)
write(*,*) result
```

Integer Data Types

C to D

This section describes language features that start with C or D.

C to D

C_ASSOCIATED

Intrinsic Module Inquiry function (Generic): *Indicates the association status of one argument, or whether two arguments are associated with the same entity.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

`result = C_ASSOCIATED(c_ptr_1[, c_ptr_2])`

c_ptr_1	(Input) Is a scalar of derived type C_PTR or C_FUNPTR.
c_ptr_2	(Optional; input) Is a scalar of the same type as *c_ptr_1*.

Results

The result is a scalar of type default logical. The result value is one of the following:

- If only *c_ptr_1* is specified, the result is false if *c_ptr_1* is a C null pointer; otherwise, the result is true.
- If *c_ptr_2* is specified, the result is false if *c_ptr_1* is a C null pointer. The result is true if *c_ptr_1* is equal to *c_ptr_2*; otherwise, the result is false.

See Also

Intrinsic Modules

ISO_C_BINDING Module

C_F_POINTER

Intrinsic Module Subroutine: *Associates a data pointer with the target of a C pointer and specifies its shape.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

```
CALL C_F_POINTER(cptr, fptr [, shape, lower])
```

cptr	(Input) Is a scalar of derived type C_PTR. Its value is the C address of an interoperable data entity, or the result of a reference to function C_LOC with a noninteroperable argument. If the value of *cptr* is the C address of a Fortran variable, it must have the TARGET attribute.
fptr	(Output) Is a data pointer. If it is an array, *shape* must be specified.
shape	(Optional, input) Must be of type integer and rank one. Its size equals the rank of *fptr*.
lower	(Optional, input) Must be of type integer and rank one. Its size equals the rank of *fptr*. It can only appear if *shape* also appears.

If the value of *cptr* is the C address of an interoperable data entity, *fptr* must be a data pointer with type and type parameters interoperable with the type of the entity. In this case, *fptr* becomes pointer-associated with the target of *cptr*.

If *fptr* is an array, it has the shape specified by *shape*. If *lower* is present, the lower bounds of *fptr* are specified by *lower*; otherwise, each lower bound is 1.

If the value of *cptr* is the result of a reference to C_LOC with a noninteroperable argument *x*, the following rules apply:

- C_LOC argument *x* (or its target) must not have been deallocated or have become undefined due to the execution of a RETURN or END statement since the reference to C_LOC.
- *fptr* is a scalar pointer with the same type and type parameters as *x*. *fptr* becomes pointer-associated with *x*, or it becomes pointer-associated with its target if *x* is a pointer.

Since the resulting data pointer *fptr* could point to a target that was not allocated with an ALLOCATE statement, *fptr* cannot be freed with a DEALLOCATE statement.

See Also

Intrinsic Modules

ISO_C_BINDING Module

C_LOC

C_F_PROCPOINTER

Intrinsic Module Subroutine: *Associates a Fortran procedure pointer with the target of a C function pointer.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

```
CALL C_F_PROCPOINTER(cptr, fptr)
```

cptr	(Input) Is a scalar of derived type C_FUNPTR. Its value is the C address of a procedure.

fptr	(Output) Is a Fortran procedure pointer. It becomes pointer-associated with the target of *cptr*.

Examples

Example 1

The following Fortran subroutine can be called from a C program that passes a pointer to a C function to be called:

```
SUBROUTINE CallIt (cp) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
TYPE(C_FUNPTR), INTENT(IN) :: cp
ABSTRACT INTERFACE
  SUBROUTINE Add_Int (i) BIND(C)
  IMPORT
  INTEGER(C_INT), INTENT(INOUT) :: i
  END SUBROUTINE Add_Int
END INTERFACE
PROCEDURE(Add_Int), POINTER :: fp
INTEGER(C_INT) :: j

CALL C_F_PROCPOINTER (cp, fp)
j = 1
CALL fp(j)
...
```

Example 2

In the following C code, a function pointer to the C function `foo` is passed to the Fortran subroutine `bar`. `bar` converts the function pointer to a procedure pointer, and calls `foo` through the converted procedure pointer.

```
main.c:
#include <stdio.h>

extern void bar_ (void (**) (int*));
extern void foo (int *a){
   printf ("  The value is %d\n", *a)
}

int main () {
   void (*fun_b)(int*) = NULL;
   int *i;
   int j = 10;

   fun_b = foo;
   i = &j;
   printf ("Test in C\n");
   fun_b (i);
   printf ("Test in Fortran\n");
   bar_ (&fun_b);
}

bar.f90
SUBROUTINE bar (c_fptr)
   USE ISO_C_BINDING
   TYPE(c_funptr)      :: c_fptr
   PROCEDURE(),POINTER :: proc_ptr
   INTEGER(c_int)      :: i = 20
```

```
   CALL c_f_procpointer (c_fptr, proc_ptr)
   CALL proc_ptr (i)

END SUBROUTINE bar
```

When these two files are compiled, linked, and executed, the output is:

```
Test in C
  The value is 10
Test in Fortran
  The value is 20
```

Intrinsic Modules

ISO_C_BINDING Module

Procedure Pointers

PROCEDURE

C_F_STRPOINTER

Intrinsic Module Subroutine (Generic): *Associates a Fortran character data pointer with a C string.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

CALL C_F_STRPOINTER(*cstrarray*, *fstrptr* [, *nchars*])

-or-

CALL C_F_STRPOINTER(*cstrptr*, *fstrptr* [, *nchars*])

cstrarray	(Input) Is a scalar rank 1 character array of type C_CHAR, with a length type parameter of one. The actual argument must have the TARGET attribute and be simply contiguous; it must be of derived type C_PTR.
cstrptr	(Input) Is a scalar with type C_PTR. It has the value of the C address of a contiguous array STRING containing *nchars* characters. It must not have a value that is the C address of a Fortran variable that does not have the TARGET attribute.
fstrptr	(Output) Is a deferred-length character pointer whose kind type is C_CHAR. If *cstrarray* appears, *fstrptr* becomes pointer-associated with the leftmost characters of the actual argument. If *cstrptr* appears, *fstrptr* becomes pointer-associated with the leftmost characters, in array element order, of STRING. The length type parameter of *fstrptr* becomes the largest value for which no C null characters appear in the sequence, and is less than or equal to *nchars* if it is present; otherwise, it is the size of *cstrarray*.

nchars	(Optional, input) Must be of type integer with a nonnegative value. It must be present if *cstrarray* is assumed-size, or if *cstrptr* appears. If *cstrarray* appears, *nchars* must not have a value greater than the size of *cstrarray*.

Examples

The following procedure prints the value of up to the first 2048 characters of the PATH environment variable returned by calling the C library function getenv:

```
SUBROUTINE print_path () BIND (C)
   USE ISO_C_BINDING
   TYPE (C_PTR) :: getenv_res
  CHARACTER(LEN=:,KIND=C_CHAR),POINTER :: path
   INTERFACE
     FUNCTION getenv (env_var) BIND (C)
       IMPORT C_PTR, C_CHAR
       TYPE (C_PTR) :: getenv
       CHARACTER(KIND=C_CHAR),INTENT(IN) :: env_var (*)
     END FUNCITON
   END INTERFACE
   getenv_res = getenv ("PATH"//C_NULL_CHAR)
   IF (.NOT. C_ASSOCIATED (getenv_res)) THEN
     PRINT *, "PATH not set"
   ELSE
     CALL C_F_STRPOINTER (getenv_res, path, 2048)
     PRINT *, TRIM (path)
   END IF
 END SUBROUTINE print_path
```

The following procedure writes a C string to a Fortran internal file. The string can be of any length. The *nchars* argument in the call to C_F_POINTER limits the length of `f_char_ptr` to no more than `n_chars` characters, which is the maximum length of the internal file:

```
 SUBROUTINE write_string (c_string, i_file) BIND (C)
   USE ISO_C_BINDING
   CHARACTER(LEN=:),INTENT(OUT) :: i_file
   CHARACTER(LEN=:,KIND=C_CHAR),TARGET,INTENT(IN) :: c_string
   CHARACTER(LEN=:,KIND=C_CHAR),POINTER :: f_char_ptr
   INTEGER :: n_chars
   n_chars = LEN(i_file)
   CALL C_F_STRPOINTER (c_string, f_char_ptr, n_chars)
   PRINT i_file, f_char_ptr
 END SUBROUTINE write_string
```

See Also

Intrinsic Modules

ISO_C_BINDING Module

C_FUNLOC

Intrinsic Module Inquiry function (Generic):
Returns the C address of a function pointer.

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

```
result = C_FUNLOC(x)
```

x	(Input) Is a procedure or a Fortran pointer of type INTEGER associated with a procedure. If *x* is a procedure pointer, it must be associated. *x* cannot be a coindexed object. If C_FUNLOC is called from a PURE procedure, *x* must be PURE.

Results

The result is a scalar of derived type C_FUNPTR. The result value represents the C address of the argument.

See Also

Intrinsic Modules

ISO_C_BINDING Module

C_LOC

Intrinsic Module Inquiry function (Generic):
Returns the C address of an argument.

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

```
result = C_LOC(x)
```

x	(Input) Is a non-coindexed variable that has the TARGET attribute. It must have interoperable type and type parameters, and it must be a non-polymorphic variable with no length type parameters, or an assumed-type variable. If it is an array, it must be contiguous with non-zero size. It cannot be a zero-length string. If it is a pointer, it must be associated. If it has the ALLOCATABLE attribute, it must be allocated.

Results

The result is a scalar of derived type C_PTR. The result value represents the C address of the argument.

The result is a value that can be used as an actual CPTR argument in a call to procedure C_F_POINTER where *fptr* has attributes that allow the pointer assignment *fptr*=>*x*. Such a call to C_F_POINTER has the effect of the pointer assignment *fptr*=>*x*.

If *x* is a scalar, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of *x* and the pointer assignment CPTR%PX=>*x* were executed.

If *x* is an array, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of *x* and the pointer assignment CPTR%PX to the first element of *x* were executed.

Intrinsic Modules

ISO_C_BINDING Module

C_F_POINTER

C_SIZEOF

Intrinsic Module Inquiry function (Generic): *Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

`result = C_SIZEOF(x)`

x	(Input) Is an interoperable data entity of any type and any rank. It must not be an assumed-size array or an assumed-rank array associated with an assumed-size array.

Results

The result is a scalar of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. If *x* is scalar, the result value is the size of *x* in bytes. If *x* is an array, the result value is the size of a single element of *x* multiplied by the number of elements in *x*.

Example

Consider the following:

```
INTEGER(4) :: S
INTEGER(4) :: T(3)
C_SIZEOF(S) ! has the value 4
C_SIZEOF(T) ! has the value 12
```

See Also

Intrinsic Modules

ISO_C_BINDING Module

SIZEOF

CACHESIZE

Inquiry Intrinsic Function (Generic): *Returns the size of a level of the memory cache.*

Syntax

`result = CACHESIZE (n)`

n	(Input) Must be scalar and of type integer.

Results

The result type and kind are the same as *n*. The result value is the number of kilobytes in the level *n* memory cache.

n = 1 specifies the first level cache; *n* = 2 specifies the second level cache; etc. If cache level *n* does not exist, the result value is 0.

Example

CACHESIZE(1) returns 16 for a processor with a 16KB first level memory cache.

CALL

Statement: *Transfers control to a subroutine subprogram.*

Syntax

```
CALL sub[( [a-arg[,a-arg]...] )]
```

sub

Is the name of the subroutine subprogram or other external procedure, or a dummy argument associated with a subroutine subprogram or other external procedure.

a-arg

Is an actual argument optionally preceded by [keyword=], where *keyword* is the name of a dummy argument in the explicit interface for the subroutine. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, the name of a procedure, a procedure pointer, or an alternate return specifier. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)

An alternate return specifier is an asterisk (*), or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement. (An alternate return is an obsolescent feature in Standard Fortran.)

Description

When the CALL statement is executed, any expressions in the actual argument list are evaluated, then control is passed to the first executable statement or construct in the subroutine. When the subroutine finishes executing, control returns to the next executable statement following the CALL statement, or to a statement identified by an alternate return label (if any).

If an argument list appears, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

An actual argument associated with a dummy procedure or a procedure pointer dummy argument must be the specific name of a procedure, an associated procedure pointer, or it must be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures). Specific names for intrinsic procedures are an obsolescent feature in the Fortran standard.

The procedure invoked by the CALL statement must be a subroutine subprogram and not a function. Calling a function as if it was a subroutine can cause unpredictable results.

Example

The following example shows valid CALL statements:

```
CALL CURVE(BASE,3.14159+X,Y,LIMIT,R(LT+2))
CALL PNTOUT(A,N,'ABCD')
CALL EXIT
CALL MULT(A,B,*10,*20,C)       ! The asterisks and ampersands denote
CALL SUBA(X,&30,&50,Y)         !     alternate returns
```

The following example shows a subroutine with argument keywords:

```
PROGRAM KEYWORD_EXAMPLE
  INTERFACE
    SUBROUTINE TEST_C(I, L, J, KYWD2, D, F, KYWD1)
    INTEGER I, L(20), J, KYWD1
    REAL, OPTIONAL :: D, F
    COMPLEX KYWD2
    ...
    END SUBROUTINE TEST_C
  END INTERFACE
  INTEGER I, J, K
  INTEGER L(20)
  COMPLEX Z1
  CALL TEST_C(I, L, J, KYWD1 = K, KYWD2 = Z1)
  ...
```

The first three actual arguments are associated with their corresponding dummy arguments by position. The argument keywords are associated by keyword name, so they can appear in any order.

Note that the interface to subroutine TEST has two optional arguments that have been omitted in the CALL statement.

The following shows another example of a subroutine call with argument keywords:

```
CALL TEST(X, Y, N, EQUALITIES = Q, XSTART = X0)
```

The first three arguments are associated by position.

The following shows another example:

```
!Variations on a subroutine call
      REAL S,T,X
      INTRINSIC NINT
      S=1.5
      T=2.5
      X=14.7
      !This calls SUB1 using keywords. NINT is an intrinsic function.
      CALL SUB1(B=X,C=S*T,FUNC=NINT,A=4.0)
!Here is the same call using an implicit reference
      CALL SUB1(4.0,X,S*T,NINT)
      CONTAINS
        SUBROUTINE sub1(a,b,c,func)
        INTEGER func
        REAL a,b,c
        PRINT *, a,b,c, func(b)
        END SUBROUTINE
      END
```

CANCEL

OpenMP* Fortran Compiler Directive: *Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.*

Syntax

```
!$OMP CANCEL construct-clause [[,] if-clause]
```

construct-clause	Is one of the following: • DO • PARALLEL • SECTIONS • TASKGROUP
if-clause	(Optional) IF (scalar-logical-expression)

The binding thread set of a CANCEL construct is the current team. The cancel region binds to the innermost enclosing construct of the type corresponding to the *construct-clause* specified in the directive specifying the innermost DO, PARALLEL, SECTIONS, or TASKGROUP construct.

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

If *construct-clause* is TASKGROUP, the CANCEL construct must be closely nested inside a TASK construct. Otherwise, the CANCEL construct must be closely nested inside an OpenMP construct that matches the type specified in *construct-clause*.

The CANCEL construct requests cancellation of the innermost enclosing region of the type specified. The request is checked at a cancellation point. When a cancellation is observed, execution jumps to the end of the canceled region.

Cancellation points are implied at certain locations, as follows:

- Implicit barriers
- BARRIER regions
- CANCEL regions
- CANCELLATION POINT regions

When cancellation of tasks occurs with a CANCEL TASKGROUP construct, the encountering task jumps to the end of its task region and is considered complete. Any task that belongs to the innermost enclosing taskgroup and has already begun execution, must run to completion or run until a cancellation point is reached. Any task that belongs to the innermost enclosing taskgroup and has not begun execution may be discarded and considered completed.

When cancellation occurs for a PARALLEL region, each thread of the binding thread set resumes execution at the end of the canceled region and any tasks that have been created by a TASK construct and their descendants are canceled according to the above taskgroup cancellation semantics.

When cancellation occurs for a DO or SECTIONS region, each thread of the binding thread set resumes execution at the end of the canceled region but no task cancellation occurs.

A DO construct that is being canceled must not have a NOWAIT or an ORDERED clause. A SECTIONS construct that is being canceled must not have a NOWAIT clause.

The behavior for concurrent cancellation of a region and a region nested within it is unspecified.

NOTE
You must release locks and similar data structures that can cause a deadlock when a CANCEL construct is encountered; blocked threads cannot be canceled.

If the canceled construct contains a REDUCTION or LASTPRIVATE clause, the final value of the REDUCTION or LASTPRIVATE variable is undefined.

All private objects or subobjects with the ALLOCATABLE attribute that are allocated inside the canceled construct are deallocated.

See Also

Syntax Rules for Compiler Directives
CANCELLATION POINT
Parallel Processing Model for information about Binding Sets

CANCELLATION POINT
OpenMP* Fortran Compiler Directive: *Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.*

Syntax
```
!$OMP CANCELLATION POINT construct-clause
```

construct-clause Is one of the following:

- DO
- PARALLEL
- SECTIONS
- TASKGROUP

This is a stand-alone directive, so there are some restrictions on its placement within a program:

- It can only be placed at a point where a Fortran executable statement is allowed.
- It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

A CANCELLATION POINT region binds to the current task region.

If *construct-clause* is TASKGROUP, the CANCELLATION POINT construct must be closely nested inside a TASK construct. Otherwise, the CANCELLATION POINT construct must be closely nested inside an OpenMP construct that matches the type specified by the *construct-clause*.

When an implicit or explicit task reaches a user-defined cancellation point, the task immediately checks for cancellation of the region specified in the clause and performs cancellation of this region if cancellation is observed. If the clause specified is TASKGROUP then the current task region is canceled.

An OpenMP program with orphaned CANCELLATION POINT constructs is non-conforming.

OpenMP Fortran Compiler Directives

CASE

Statement: *Marks the beginning of a CASE construct. A CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.*

Syntax

```
[name:] SELECT CASE (expr)
[CASE (case-value [, case-value] ...) [name]
   block]...
[CASE DEFAULT [name]
   block]
END SELECT [name]
```

name — Is the name of the CASE construct.

expr — Is a scalar expression of type integer, logical, or character (enclosed in parentheses). Evaluation of this expression results in a value called the *case index*.

case-value — Is one or more scalar integer, logical, or character initialization expressions enclosed in parentheses. Each *case-value* must be of the same type and kind parameter as *expr*. If the type is character, *case-value* and *expr* can be of different lengths, but their kind parameter must be the same.

Integer and character expressions can be expressed as a range of case values, taking one of the following forms:

```
low:high
low:
:high
```

Case values must not overlap.

block — Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified in a SELECT CASE statement, the same name must appear in the corresponding END SELECT statement. The same construct name can optionally appear in any CASE statement in the construct. The same construct name must not be used for different named constructs in the same scoping unit.

The case expression (*expr*) is evaluated first. The resulting case index is compared to the case values to find a matching value (there can only be one). When a match occurs, the block following the matching case value is executed and the construct terminates.

The following rules determine whether a match occurs:

- When the case value is a single value (no colon appears), a match occurs as follows:

Data Type	A Match Occurs If:
Logical	case-index .EQV. case-value
Integer or Character	case-index = = case-value

- When the case value is a range of values (a colon appears), a match depends on the range specified, as follows:

Range	A Match Occurs If:
low **:**	case-index >= low
: high	case-index <= high
low **:** high	low <= case-index <= high

The following are all valid case values:

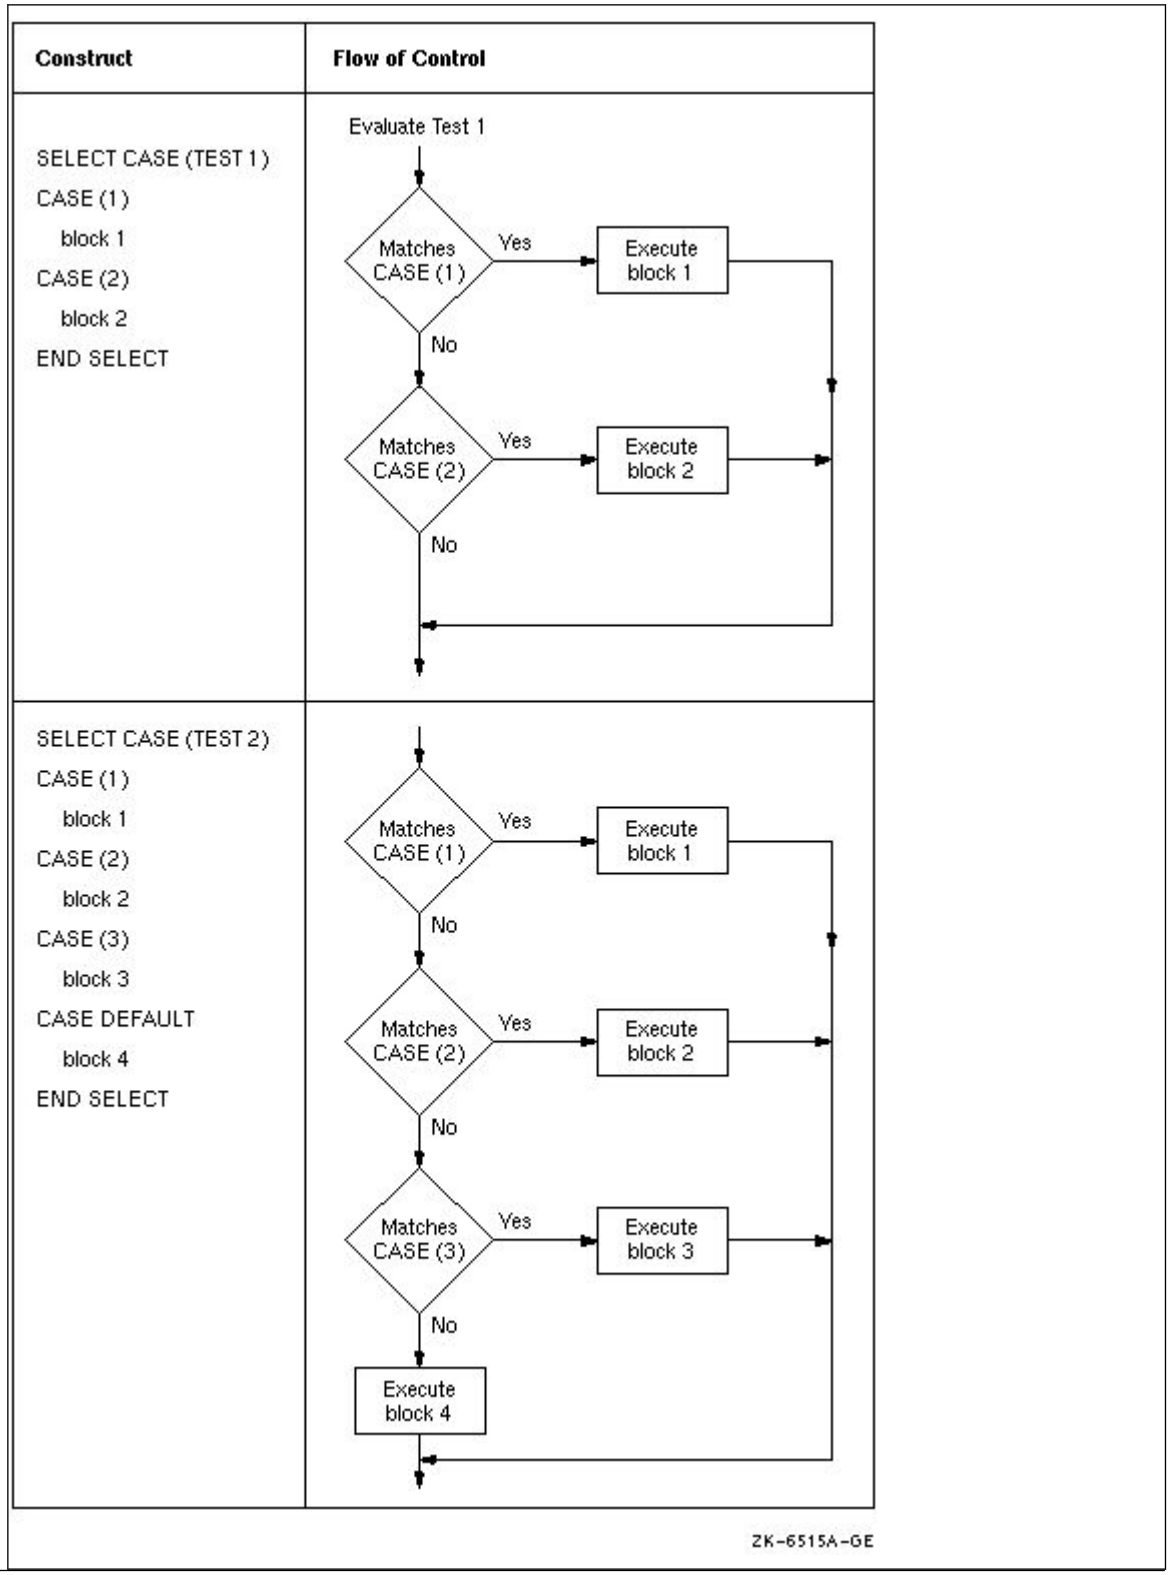
```
CASE (1, 4, 7, 11:14, 22)      ! Individual values as specified:
                               !     1, 4, 7, 11, 12, 13, 14, 22
CASE (:-1)                     ! All values less than zero
CASE (0)                       ! Only zero
CASE (1:)                      ! All values above zero
```

If no match occurs but a CASE DEFAULT statement is present, the block following that statement is executed and the construct terminates.

If no match occurs and no CASE DEFAULT statement is present, no block is executed, the construct terminates, and control passes to the next executable statement or construct following the END SELECT statement.

The following figure shows the flow of control in a CASE construct:

Flow of Control in CASE Constructs



You cannot use branching statements to transfer control to a CASE statement. However, branching to a SELECT CASE statement is allowed. Branching to the END SELECT statement is allowed only from within the CASE construct.

Example

The following are examples of CASE constructs:

```
INTEGER FUNCTION STATUS_CODE (I)
  INTEGER I
  CHECK_STATUS: SELECT CASE (I)
  CASE (:-1)
    STATUS_CODE = -1
  CASE (0)
    STATUS_CODE = 0
  CASE (1:)
    STATUS_CODE = 1
  END SELECT CHECK_STATUS
END FUNCTION STATUS_CODE

SELECT CASE (J)
CASE (1, 3:7, 9)    ! Values: 1, 3, 4, 5, 6, 7, 9
  CALL SUB_A
CASE DEFAULT
  CALL SUB_B
END SELECT
```

The following three examples are equivalent:

```
1. SELECT CASE (ITEST .EQ. 1)
   CASE (.TRUE.)
     CALL SUB1 ()
   CASE (.FALSE.)
     CALL SUB2 ()
   END SELECT

2. SELECT CASE (ITEST)
   CASE DEFAULT
     CALL SUB2 ()
   CASE (1)
     CALL SUB1 ()
   END SELECT

3. IF (ITEST .EQ. 1) THEN
     CALL SUB1 ()
   ELSE
     CALL SUB2 ()
   END IF
```

The following shows another example:

```
CHARACTER*1 cmdchar
GET_ANSWER: SELECT CASE (cmdchar)
CASE ('0')
   WRITE (*, *) "Must retrieve one to nine files"
CASE ('1':'9')
   CALL RetrieveNumFiles (cmdchar)
CASE ('A', 'a')
   CALL AddEntry
CASE ('D', 'd')
   CALL DeleteEntry
```

```
CASE ('H', 'h')
   CALL Help
CASE DEFAULT
   WRITE (*, *) "Command not recognized; please use H for help"
END SELECT GET_ANSWER
```

See Also

Execution Control

CDFLOAT

Portability Function: *Converts a COMPLEX(4) argument to double-precision real type.*

Module

USE IFPORT

Syntax

`result = CDFLOAT (input)`

input	(Input) COMPLEX(4). The value to be converted.

Results

The result type is REAL(8).

CEILING

Elemental Intrinsic Function (Generic): *Returns the smallest integer greater than or equal to its argument.*

Syntax

`result = CEILING (a[,kind])`

a	(Input) Must be of type real.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the smallest integer greater than or equal to *a*.

The setting of compiler options specifying integer size can affect this function.

Example

CEILING (4.8) has the value 5.

CEILING (-2.55) has the value -2.0.

The following shows another example:

```
INTEGER I, IARRAY(2)
I = CEILING(8.01) ! returns 9
I = CEILING(-8.01) ! returns -8
IARRAY = CEILING((/8.01,-5.6/)) ! returns (9, -5)
```

See Also

FLOOR

CFI_address

C function prototype: *Returns the C address of an object described by a C descriptor.*

Syntax

```
void *CFI_address (const CFI_cdesc_t *dv,
                   const CFI_index_t subscripts[]);
```

Formal Parameters:

dv	The address of a C descriptor describing the object. The object must not be an unallocated allocatable variable or a pointer that is not associated.
subscripts	A null pointer or the address of an array of type `CFI_index_t`. If the object is an array, subscripts must be the address of an array of type `CFI_index_t` with at least *n* elements, where *n* is the rank of the object. The value of subscripts [*i*] must be within the bounds of dimension *i* specified by the `dim` member of the C descriptor.

Result Value

If the object is an array of rank *n*, the result is the C address of the element of the object that the first *n* elements of the subscripts argument would specify if used as subscripts. If the object is scalar, the result is its C address.

Example

If *dv* is the address of a C descriptor for the Fortran array A declared as follows:

```
REAL(C_FLOAT) :: A(100, 100)
```

then the following code calculates the C address of A(5, 10):

```
CFI_index_t subscripts[2];
float *address;
subscripts[0] = 4;
subscripts[1] = 9;
address = (float *) CFI_address(dv, subscripts );
```

See Also

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_allocate

C function prototype: *Allocates memory for an object described by a C descriptor.*

Syntax

```
int CFI_allocate (CFI_cdesc_t *dv,
                  const CFI_index_t lower_bounds[]),
                  const CFI_index_t upper_bounds[],
                  size_t elem_len);
```

Formal Parameters:

dv	The address of a C descriptor specifying the rank and type of the object. The `base_addr` member of the C descriptor is a null pointer. If the type is not a character type, the *elem_len* member must specify the element length. The attribute member must have a value of `CFI_attribute_allocatable` or `CFI_attribute_pointer`.
lower_bounds	The address of an array with at least dv->rank elements. The first dv->rank elements of *lower_bounds* provide the lower Fortran bounds for each corresponding dimension of the object.
upper_bounds	The address of an array with at least dv->rank elements. The first dv->rank elements of *upper_bounds* provide the upper Fortran bounds for each corresponding dimension of the object.
elem_len	If the type specified in the C descriptor type is a Fortran character type, the value of *elem_len* is the storage size in bytes of an element of the object; otherwise, *elem_len* is ignored.

Description

Successful execution of CFI_allocate allocates memory for the object described by the C descriptor with the address dv using the same mechanism as the Fortran ALLOCATE statement, and assigns the address of that memory to dv->`base_addr`.

The first dv->rank elements of the *lower_bounds* and *upper_bounds* arguments provide the lower and upper Fortran bounds, respectively, for each corresponding dimension of the object. The supplied lower and upper bounds override any current dimension information in the C descriptor. If the rank is zero, the *lower_bounds* and *upper_bounds* arguments are ignored.

If the type specified in the C descriptor is a character type, the supplied element length overrides the current element-length information in the descriptor.

If an error is detected, the C descriptor is not modified.

Result Value

The result is an error indicator.

Example

If *dv* is the address of a C descriptor for the Fortran array A declared as follows:

```
REAL, ALLOCATABLE :: A(:, :)
```

and the array is not allocated, the following code allocates it to be of shape [100, 500]:

```
CFI_index_t lower[2], upper[2];
int ind;
lower[0] = 1; lower[1] = 1;
upper[0] = 100; upper[1] = 500;
ind = CFI_allocate(dv, lower, upper, 0);
```

See Also

ALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_deallocate

C function prototype: *Deallocates memory for an object described by a C descriptor.*

Syntax

```
int CFI_deallocate (CFI_cdesc_t *dv);
```

Formal Parameters:

dv	The address of a C descriptor describing the object. It must have been allocated using the same mechanism as the Fortran ALLOCATE statement. If the object is a pointer, it must be associated with a target satisfying the conditions for successful deallocation by the Fortran DEALLOCATE statement.

Description

Successful execution of CFI_deallocate deallocates memory for the object using the same mechanism as the Fortran DEALLOCATE statement, and the `base_addr` member of the C descriptor becomes a null pointer.

If an error is detected, the C descriptor is not modified.

Result Value

The result is an error indicator.

Example

If *dv* is the address of a C descriptor for the Fortran array A declared as follows:

```
REAL, ALLOCATABLE :: A(:, :)
```

and the array is allocated, the following code deallocates it:

```
int ind;
ind = CFI_deallocate(dv);
```

See Also

ALLOCATE
DEALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_establish

C function prototype: *Establishes a C descriptor.*

Syntax

```
int CFI_establish(CFI_cdesc_t *dv, void *base_addr,
                  CFI_attribute_t attribute,
                  CFI_type_t type, size_t elem_len,
                  CFI_rank_t rank,
                  const CFI_index_t extents[]);
```

Formal Parameters:

dv	The address of a data object large enough to hold a C descriptor of the rank specified by *rank*. It must not have the same value as either a C formal parameter that corresponds to a Fortran actual argument

	or a C actual argument that corresponds to a Fortran dummy argument. It must not be the address of a C descriptor that describes an allocated allocatable object.
base_addr	A null pointer or the base address of the object to be described. If it is not a null pointer, it must be the address of a contiguous storage sequence that is appropriately aligned for an object of the type specified by *type*.
attribute	One of the attribute codes in Table "Macros for attribute codes" in C Typedefs and Macros for interoperability. If it is `CFI_attribute_allocatable`, *base_addr* must be a null pointer.
type	One of the type codes in Table "Macros for type codes" in C Typedefs and Macros for interoperability.
elem_len	If the type is `CFI_type_struct`, `CFI_type_other`, or a Fortran character type code, *elem_len* must be greater than zero and equal to the storage size in bytes of an element of the object. Otherwise, *type* is ignored.
rank	A value in the range 0 ≤ *rank* ≤ `CFI_MAX_RANK`. It specifies the rank of the object.
extents	This is ignored if rank is equal to zero or if *base_addr* is a null pointer. Otherwise, it must be the address of an array with rank elements; the value of each element must be nonnegative, and extents[*i*] specifies the extent of dimension *i* of the object.

Description

Successful execution of CFI_establish updates the object with the address *dv* to be an established C descriptor for a nonallocatable nonpointer data object of known shape, an unallocated allocatable object, or a data pointer.

If *base_addr* is not a null pointer, it is the address for a nonallocatable entity that is a scalar or a contiguous array. If the attribute argument has the value `CFI_attribute_pointer`, the lower bounds of the object described by *dv* are set to zero. If *base_addr* is a null pointer, the established C descriptor is for an unallocated allocatable, a disassociated pointer, or is a C descriptor that has the attribute `CFI_attribute_other` but does not describe a data object. If *base_addr* is the C address of a Fortran data object, the *type* and *elem_len* arguments must be consistent with the type and type parameters of the Fortran data object.

The remaining properties of the object are given by the other arguments.

CFI_establish is used to initialize a C descriptor declared in C with `CFI_CDESC_T` before passing it to any other functions as an actual argument, in order to set the rank, attribute, type and element length.

A C descriptor with attribute `CFI_attribute_other` and a *base_addr* that is a null pointer can be used as the argument result in calls to `CFI_section` or `CFI_select_part`, which will produce a C descriptor for a nonallocatable nonpointer data object.

If an error is detected, the object with the address *dv* is not modified.

Result Value

The result is an error indicator.

Example

The following code fragment establishes a C descriptor for an unallocated rank-one allocatable array that can be passed to Fortran for allocation there:

```
CFI_rank_t rank;
CFI_CDESC_T(1) field;
int ind;
rank = 1;
ind = CFI_establish((CFI_cdesc_t *)&field, NULL,
CFI_attribute_allocatable,
CFI_type_double, 0, rank, NULL);
```

If the following Fortran type definition is specified:

```
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
```

and a Fortran subprogram that has an assumed-shape dummy argument of type T, the following code fragment creates a descriptor `a_fortran` for an array of size 100 that can be used as the actual argument in an invocation of the subprogram from C:

```
typedef struct {double x; double _Complex y;} t;
t a_c[100];
CFI_CDESC_T(1) a_fortran;
int ind;
CFI_index_t extent[1];

extent[0] = 100;
ind = CFI_establish((CFI_cdesc_t *)&a_fortran, a_c,
CFI_attribute_other,
CFI_type_struct, sizeof(t), 1, extent);
```

See Also

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_is_contiguous

C function prototype: *Tests contiguity of an array.*

Syntax

```
int CFI_is_contiguous(const CFI_cdesc_t *dv);
```

Formal Parameters:

dv	The address of a C descriptor describing an array. The `base_addr` member of the C descriptor must not be a null pointer.

Result Value

The value of the result is 1 if the array described by *dv* is contiguous; otherwise, 0.

Since assumed-size and allocatable arrays are always contiguous, the result of CFI_is_contiguous on a C descriptor for such an array is 1.

See Also

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_section

C function prototype: *Updates a C descriptor for an array section for which each element is an element of a given array.*

Syntax

```
int CFI_section(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                          const CFI_index_t lower_bounds[],
                          const CFI_index_t upper_bounds[],
                          const CFI_index_t strides[]);
```

Formal Parameters:

result

The address of a C descriptor with rank equal to the rank of *source* minus the number of zero *strides*. The attribute member must have the value `CFI_attribute_other` or `CFI_attribute_pointer`. If the value of result is the same as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument, the attribute member must have the value `CFI_attribute_pointer`.

Successful execution of CFI_section updates the `base_addr` and `dim` members of the C descriptor with the address result to describe the array section determined by *source*, *lower_bounds*, *upper_bounds*, and *strides*, as follows:

- The array section is equivalent to the Fortran array section SOURCE(*sectsub*1, *sectsub*2, ... *sectsub*n), where SOURCE is the array described by *source*, *n* is the rank of that array, and *sectsubi* is the subscript *loweri* if *stridesi* is zero, and the section subscript *loweri* : *upperi* : *stridei* otherwise.
- The value of *loweri* is the lower bound of dimension *i* of SOURCE if *lower_bounds* is a null pointer and *lower_bounds*[*i*] otherwise.
- The value of *upperi* is the upper bound of dimension *i* of SOURCE if *upper_bounds* is a null pointer and *upper_bounds*[*i*] otherwise.
- The value of *stridei* is 1 if *strides* is a null pointer and *strides*[*i*] otherwise. If *stridei* has the value zero, *loweri* must have the same value as *upperi*.

source

The address of a C descriptor that describes a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer. The `elem_len` and `type` members of source must have the same values as the corresponding members of result.

lower_bounds

A null pointer or the address of an array with at least source->rank elements. If it is not a null pointer, and *stridei* is zero or (*upperi* −*lower_bounds*[*i*] + *stridei*)/*stridei* > 0, the value of *lower_bounds*[*i*] must be within the bounds of dimension *i* of SOURCE.

upper_bounds

A null pointer or the address of an array with at least source->rank elements. If source describes an assumed-size array, *upper_bounds* must not be a null pointer. If it is not a null pointer and *stridei* is zero

	or (*upper_bounds*[*i*] − *loweri* + *stridei*)/*stridei* > 0, the value of *upper_bounds*[*i*] must be within the bounds of dimension *i* of SOURCE.
strides	A null pointer or the address of an array with at least source->rank elements.

If an error is detected, the C descriptor with the address result is not modified.

Result Value

The result is an error indicator.

Example

If source is already the address of a C descriptor for the rank-one Fortran array A, the lower bounds of A are equal to 1, and the lower bounds in the C descriptor are equal to 0, the following code fragment establishes a new C descriptor section and updates it to describe the array section A(3::5):

```
CFI_index_t lower[1], strides[1];
CFI_CDESC_T(1) section;
int ind;
lower[0] = 2;
strides[0] = 5;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, NULL, strides);
```

If source is already the address of a C descriptor for a rank-two Fortran assumed-shape array A with lower bounds equal to 1, the following code fragment establishes a C descriptor and updates it to describe the rank-one array section A(:, 42):

```
CFI_index_t lower[2], upper[2], strides[2];
CFI_CDESC_T(1) section;
int ind;
lower[0] = source->dim[0].lower_bound;
upper[0] = source->dim[0].lower_bound + source->dim[0].extent - 1;
strides[0] = 1;
lower[1] = upper[1] = source->dim[1].lower_bound + 41;
strides[1] = 0;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, upper, strides);
```

See Also

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_select_part

C function prototype: *Updates a C descriptor for an array section for which each element is a part of the corresponding element of an array.*

Syntax

```
int CFI_select_part(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                    size_t displacement, size_t elem_len);
```

Formal Parameters:

result	The address of a C descriptor; result->rank must have the same value as source->rank and result->attribute must have the value `CFI_attribute_other` or `CFI_attribute_pointer`. If the address specified by *result* is the value of a C formal parameter that corresponds to a Fortran actual argument or of a C actual argument that corresponds to a Fortran dummy argument, result->attribute must have the value `CFI_attribute_pointer`. The value of result->type specifies the type of the array section.
source	The address of a C descriptor for a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer.
displacement	A value 0 ≤ *displacement* ≤ *source->elem_len* − 1, and the sum of the *displacement* and the size in bytes of an element of the array section must be less than or equal to *source->elem_len*. The address displacement bytes greater than the value of source->`base_addr` is the base of the array section and must be appropriately aligned for an object of the type of the array section.
elem_len	A value equal to the storage size in bytes of an element of the array section if result->type specifies a Fortran character type; otherwise, *elem_len* is ignored.

Description

Successful execution of CFI_select_part updates the `base_addr`, `dim`, and `elem_len` members of the C descriptor with the address result for an array section for which each element is a part of the corresponding element of the array described by the C descriptor with the address source. The part must be a component of a structure, a substring, or the real or imaginary part of a complex value.

If an error is detected, the C descriptor with the address result is not modified.

Result Value

The result is an error indicator.

Example

If source is already the address of a C descriptor for the Fortran array A declared as follows:

```
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
TYPE(T) A(100)
```

then the following code fragment establishes a C descriptor for the array A%Y:

```
typedef struct {
double x; double _Complex y;
} t;
CFI_CDESC_T(1) component;
CFI_cdesc_t * comp_cdesc = (CFI_cdesc_t *)&component;
```

```
CFI_index_t extent[] = { 100 };
(void)CFI_establish(comp_cdesc, NULL, CFI_attribute_other,
                    CFI_type_double_Complex,
                    sizeof(double _Complex), 1, extent);
(void)CFI_select_part(comp_cdesc, source, offsetof(t,y), 0);
```

C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_setpointer

C function prototype: *Updates a C descriptor for a Fortran pointer to be associated with the whole of a given object or to be disassociated.*

Syntax

```
int CFI_setpointer(CFI_cdesc_t *result, CFI_cdesc_t *source,
                   const CFI_index_t lower_bounds[]);
```

Formal Parameters:

result	The address of a C descriptor for a Fortran pointer. It is updated using information from the *source* and *lower_bounds* arguments.
source	A null pointer or the address of a C descriptor for a nonallocatable nonpointer data object, an allocated allocatable object, or a data pointer object. If *source* is not a null pointer, the corresponding values of the `elem_len`, `rank`, and `type` members must be the same in the C descriptors with the addresses *source* and *result*.
lower_bounds	If source is not a null pointer and source->rank is nonzero, *lower_bounds* must be a null pointer or the address of an array with at least source->rank elements.

Description

Successful execution of `CFI_setpointer` updates the `base_addr` and `dim` members of the C descriptor with the address result as follows:

- If *source* is a null pointer or the address of a C descriptor for a disassociated pointer, the updated C descriptor describes a disassociated pointer.
- Otherwise, the C descriptor with the address result becomes a C descriptor for the object described by the C descriptor with the address source, except that if source->rank is nonzero and *lower_bounds* is not a null pointer, the lower bounds are replaced by the values of the first source->rank elements of the *lower_bounds* array.

Result Value

The result is an error indicator.

Example

If `ptr` is already the address of a C descriptor for an array pointer of rank 1, the following code updates it to be a C descriptor for a pointer to the same array with lower bound 0:

```
CFI_index_t lower_bounds[1];
int ind;
lower_bounds[0] = 0;
ind = CFI_setpointer(ptr, ptr, lower_bounds);
```

CHANGEDIRQQ

Portability Function: *Makes the specified directory the current, default directory.*

Module

USE IFPORT

Syntax

`result = CHANGEDIRQQ (dir)`

dir	(Input) Character*(*). Directory to be made the current directory.

Results

The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..

If you do not specify a drive in the *dir* string, the named directory on the current drive becomes the current directory. If you specify a drive in *dir*, the named directory on the specified drive becomes the current directory.

Example

```
  USE IFPORT
  LOGICAL(4) status
  status = CHANGEDIRQQ('d:\fps90\bin'))
! We are now CCed to 'd:\fps90\bin'
  status = CHANGEDIRQQ('bessel')
! We are now CCed to 'd:\fps90\bin\bessel'
```

CHANGEDRIVEQQ

Portability Function: *Makes the specified drive the current, default drive.*

Module

USE IFPORT

Syntax

```
result = CHANGEDRIVEQQ (drive)
```

drive	(Input) Character*(*). String beginning with the drive letter.

Results

The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE. On Linux* systems, the result is always .FALSE..

Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of *drive*. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.

Example

```
USE IFPORT
LOGICAL(4) status
status = CHANGEDRIVEQQ('d')
```

CHANGE TEAM and END TEAM

Statement: *Changes the current team of each image that executes the statement.*

Syntax

The CHANGE TEAM construct takes the following form:

```
[name:] CHANGE TEAM (team-variable [, coarray-association-list][, sync-stat-list])
   block
END TEAM [([sync-stat-list])] [name]
```

name	(Optional) Is the name of the CHANGE TEAM construct.
team-variable	Is a scalar variable of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV.
coarray-association	(Optional) Is *codimension-decl* => *selector*
codimension-decl	Is coarray-name [coarray-spec]
selector	Is a named coarray.
sync-stat	(Optional) Is STAT= *stat-var* or ERRMSG = *err-var*
stat-var	Is a scalar integer variable in which the status of the FORM TEAM operation is stored.
err-var	Is a scalar default character variable in which explanatory text is stored if an error occurs.

block Is a sequence of zero or more statements or constructs.

The *sync-stat-list* items can appear in any order, but each *sync-stat* specifier may appear at most once. A *selector* may appear only once in *selector-list*. *stat-var* and *err-var* cannot be coindexed variables. *team-variable* must have been previously defined by the execution of a FORM TEAM statement.

Description

A CHANGE TEAM statement begins the CHANGE TEAM construct. The current team of each image that executes a CHANGE team statement becomes the team specified by the team variable. This remains the current team of the image until another CHANGE TEAM construct is executed by the image, or until the corresponding END TEAM statement is executed. The current team of each image executing an END TEAM statement becomes the team that was current prior to execution of the corresponding CHANGE TEAM statement.

Branching into or out of a CHANGE TEAM construct is not permitted. A branch to an END TEAM statement is permitted only from within the corresponding CHANGE TEAM construct. An EXIT statement in a CHANGE TEAM construct is effectively the same as a branch to the END TEAM statement of the construct. Within a CHANGE TEAM construct, a CYCLE or EXIT statement is not allowed if it belongs to an outer construct. A RETURN statement may not appear in a CHANGE TEAM construct.

If a construct name appears on the CHANGE TEAM statement of the construct, the same name must also appear on the END TEAM construct. If a construct name appears on an END TEAM statement, the same construct name must appear on the corresponding CHANGE TEAM statement. The construct name must not be the same as any other construct name in the scoping unit.

The purpose of the *coarray-association* is to redefine the codimensions of a coarray during execution of the CHANGE TEAM construct. The associating entity is a coarray with the corank and cobounds specified in the *codimension-decl*. This means the coshape and cobounds of an associating entity can be different from that of the selector. When the CHANGE TEAM statement is executed, the selectors must all be established coarrays.

The coarray name in a *coarray-association* must not be the same as the name as the name of another coarray or of a selector in the CHANGE TEAM statement. The coarray names specified in the *codimension-decl* are associate names associated with their corresponding selectors. The type and type parameters of the associating entity is that of its selector. The associating entity is polymorphic if the selector is polymorphic, in which case the associating entity assumes the dynamic type and type parameters of the selector.

On each active image that executes the CHANGE TEAM statement, the team variables must have been defined by corresponding execution of the same FORM TEAM statement. The current team executing prior to the CHANGE TEAM statement must be the same team that executed the FORM TEAM statement that defined the team variables. On each image, the team variable specified in the CHANGE TEAM statement cannot become undefined or redefined during execution of the construct.

An allocatable coarray that has an allocation status of allocated when the CHANGE TEAM construct is entered cannot be deallocated during execution of the construct. Allocatable coarrays that are allocated during the CHANGE TEAM construct and remain allocated at the end of the construct are deallocated upon exit from the construct. This is true even if the allocatable coarray has the SAVE attribute.

Each image executing the CHANGE TEAM statement is implicitly synchronized with all the other active images that will be on the same team after execution of the CHANGE TEAM construct. Execution of the statements forming the block of the CHANGE TEAM construct are delayed until all images on the new team have entered the construct. The construct completes execution when the END TEAM statement is executed. The images of the team executing the construct are implicitly synchronized when the END TEAM statement is executed.

If STAT= is specified in a CHANGE TEAM or END TEAM statement, *stat-var* becomes defined with the value 0 if no error condition occurs. If the team executing the statement contains a stopped image, *stat-var* becomes defined with the value STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. If the team contains a failed image and no other error condition occurs, *stat-var* becomes defined with the value

STAT_FAILED_IMAGE defined in the module ISO_FORTRAN_ENV. Otherwise, *stat-var* becomes defined with a positive integer value other than STAT_FAILED_IMAGE or STAT_STOPPED_IMAGE. If STAT= is not specified, and the team contains a stopped or failed image, or if any other error occurs, error termination is initiated.

If ERRMSG= is specified in a CHANGE TEAM or an END TEAM statement and an error condition occurs, *err-var* becomes defined with a character string containing an informative message about the error. The string is truncated or padded according to the rules of intrinsic assignment. If no error occurs, *err-var* is unchanged.

Examples

Example 1:

```
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)    :: odd_even
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
CHANGE TEAM (odd_even)
! Segment 1
 . . .
END TEAM
! Segment 2
. . .
END PROGRAM
```

If a team with 8 images executes the above code, two teams are formed. Team number 1 contains the odd numbered images [1, 3, 5, 7] of the parent team with new image indices [1, 2, 3, 4], and team number 2 contains the even numbered images [2, 4, 6, 8] of the parent team with new image indices [1, 2, 3, 4].

Segment 1 can be executed by team number 1 once images 1, 3, 5, and 7 of the initial team have arrived at the CHANGE TEAM construct. Team number 1 can execute segment 2 once the same images have executed the END TEAM statement. Similarly, segment 1 can be executed by team 2 only after image 2, 4, 6, and 8 have all arrived at the CHANGE TEAM statement, and they can execute segment 2 after they have all reached the END TEAM statement.

Example 2:

```
USE ISO_FORTRAN_ENV
INTEGER, PARAMETER :: n = 4
TYPE (TEAM_TYPE)      :: column
REAL,CODIMENSION[n, *]:: co_array
INTEGER,DIMENSION(2)           :: my_cosubscripts
my_cosubscripts (:)   = THIS_IMAGE(co_array)
FORM TEAM (my_cosubscripts(2), column, NEW_INDEX = my_cosubscripts(1))
CHANGE TEAM (column, ca[*] => co_array)
 ….
END TEAM
```

If there are 16 images on the initial team, the scalar coarray `co_array` will be distributed across a 4 x 4 grid of processors. Execution of the FORM TEAM statement divides the initial team into four teams of four images. Each team contains the images of one column of the grid of processors. The team number of each team is the column number in the processor grid, and the image indices on each new team are the row indices of the processor grid. Inside the CHANGE TEAM construct, the image pattern is a 1 x 4 pattern.

On team 1, ca[1] is co_array[1, 1], ca[2] is co_array[2,1], …, and ca[4] is coarray[4, 1]. On team 2, ca[1] is co_array[1, 2], ca[2] is co_array [2,2], …, and ca[4] is co_array[2, 4]. On team 3, ca[1] is co_array[1, 3], ca[2] is co_array[2 ,3], …, and ca[4] is co_array[4, 3]. And on team 4, ca[1] is co_array[1, 4], ca[2] is co_array[2, 4], …, and ca[4] is co_array[4, 4].

`co_array`'s cosubscripts:

1,1	1,2	1,3	1,4
2,1	2,2	2,3	2,4

3,1	3,2	3,3	3,4
4,1	4,2	4,3	4,4

`ca`'s cosubscripts on each team:

Team Number	1	2	3	4
	1,1	1,2	1,3	1,4
	2,1	2,2	2,3	2,4
	3,1	3,2	3,3	3,4
	4,1	4,2	4,3	4,4

Example 3:

```
   USE ISO_FORTRAN_ENV
   TYPE (TEAM_TYPE)    :: one_or_two
   IF (THIS_IMAGE() .LE. NUM_IMAGES() / 2) THEN
      new_team = 1
   ELSE
      new_team = 2
   END IF
   FORM TEAM (new_team, one_or_two)
   SYNC ALL
   CHANGE TEAM (one_or_two)
      ! Segment 1
      . . .
   END TEAM
   SYNC ALL
   ! Segment 2
   . . .
   END PROGRAM
```

In the above case, the FORM TEAM statement creates two teams, team 1 and team 2. The SYNC ALL statement before the CHANGE TEAM statement prevents either team from entering the CHANGE TEAM construct until all images of the other team are ready to enter it also. Similarly, the SYNC ALL after the END TEAM statement prevents either team from executing segment 2 until all images of the other team have exited the CHANGE TEAM construct.

Example 4:

This example divides a 4x4 grid of images into 4 2x2 grids of images. The image indices of the 4x4 grid are:

1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

The 2x2 grids are laid out and identified symbolically and with team numbers as:

top_left (1,1)	top_right (1,2)
bot_left (2,1)	bot_right (2,2)

The image numbers on each of the teams in the 2x2 grids become:

1	3	1	3
2	4	2	4
1	3	1	3

2	4	2	4

```
PROGRAM MAIN
USE ISO_FORTRAN_ENV
INTEGER,PARAMETER :: top_left = 11, bot_left = 21, top_right = 12, bot_right = 22
INTEGER,DIMENSION(16) :: quads =   [top_left, top_left, bot_left, bot_left, &
                                    top_left, top_left, bot_left, bot_left, &
                                    top_right, top_right, bot_right, bot_right, &
                                    top_right, top_right, bot_right, bot_right]
INTEGER,DIMENSION(16)      :: images = [1, 2, 1, 2, 3, 4, 3, 4, 1, 2, 1, 2, 3, 4, 3, 4]
TYPE (TEAM_TYPE)           :: quadrants, original_team
REAL                       :: co_array1[4,*], co_array2 [4, *]
INTEGER                    :: me

original_team = GET_TEAM(INITIAL_TEAM)   ! Create variable describing initial team
me = THIS_IMAGE()
FORM TEAM (quads(me), quadrants, NEW_INDEX=images(me))
CHANGE TEAM (quadrants, ca[2, *] => co_array1)
x  = ca[3, TEAM_NUMBER=top_right]
. . .
END TEAM
. . .
END PROGRAM
```

Here the CHANGE TEAM statement remaps the coarray co_array1 to 2x2 grids within each team accessed by the associate name ca. The assignment statement in the CHANGE TEAM construct assigns the value of ca[3] on team number 21 to x on all images of the initial team, assuming all four subteams execute the CHANGE TEAM construct. ca[3, TEAM_NUMBER=top_left] is co_array[1, 4] of the initial team located on image 13 of the initial team.

CHAR

Elemental Intrinsic Function (Generic): *Returns the character in the specified position of the processor's character set. It is the inverse of the function ICHAR.*

Syntax

`result = CHAR (i[,kind])`

i	(Input) Must be of type integer with a value in the range 0 to n - 1, where *n* is the number of characters in the processor's character set.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is of type character with length 1. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is the character in position *i* of the processor's character set. ICHAR(CHAR (*i*, *kind*(*c*))) has the value I for 0 to n - 1 and CHAR(ICHAR(*c*), *kind*(*c*)) has the value *c* for any character *c* capable of representation in the processor.

Specific Name	Argument Type	Result Type
	INTEGER(1)	CHARACTER
	INTEGER(2)	CHARACTER
CHAR [1]	INTEGER(4)	CHARACTER
	INTEGER(8)	CHARACTER

[1]This specific function cannot be passed as an actual argument.

Example

CHAR (76) has the value `'L'`.

CHAR (94) has the value `'^'`.

CHARACTER

Statement: *Specifies the CHARACTER data type.*

Syntax

```
CHARACTER ([LEN=]len [, [KIND=]n])
CHARACTER (KIND=n [, [LEN=]len])
CHARACTER* len
```

n — Is kind 1.

len — Is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

Example

```
C
C   Length of wt and vs is 10, city is 80, and ch is 1
C
    CHARACTER wt*10, city*80, ch
    CHARACTER (LEN = 10), PRIVATE :: vs
    CHARACTER*(*) arg !declares a dummy argument
C   name and plume are ten-element character arrays
C   of length 20
    CHARACTER name(10)*20
    CHARACTER(len=20), dimension(10):: plume
C
C   Length of susan, emily, and naomi are 2, karen is 12,
```

```
C   olivia is a 79-member array of length 2
C
    CHARACTER(2) susan, emily, karen*12, naomi, olivia(79)
```

See Also

Character Data Type
Character Constants

Declaration Statements for Character Types

CHDIR

Portability Function: *Changes the default directory.*

Module

USE IFPORT

Syntax

`result = CHDIR(dir_name)`

dir_name	(Input) Character*(*). Name of a directory to become the default directory.

Results

The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The named directory does not exist.
- ENOTDIR: The *dir_name* parameter is not a directory.

Example

```
     use ifport
     integer(4) istatus, enoent, enotdir
     character(255)  newdir
     character(300)  prompt, errmsg

     prompt = 'Please enter directory name: '
10   write(*,*)  TRIM(prompt)
     read *, newdir
     ISTATUS = CHDIR(newdir)
     select case (istatus)
       case (2)  ! ENOENT
         errmsg = 'The directory '//TRIM(newdir)//' does not exist'
       case (20) ! ENOTDIR
         errmsg = TRIM(newdir)//' is not a directory'
       case (0) ! NO error
         goto 40
       case default
         write (errmsg,*) 'Error with code ', istatus
      end select

      write(*,*)  TRIM(errmsg)
      goto 10
```

```
40    write(*,*) 'Default directory successfully changed.'
end
```

See Also

CHANGEDIRQQ

CHMOD

Portability Function: *Changes the access mode of a file.*

Module

USE IFPORT

Syntax

`result = CHMOD (name,mode)`

name

(Input) Character*(*). Name of the file whose access mode is to be changed. Must have a single path.

mode

(Input) Character*(*). File permission: either Read, Write, or Execute. The *mode* parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

Permission bit	Description	Action
4000	Set user ID on execution	Windows: Ignored; never true Linux: Settable
2000	Set group ID on execution	Windows: Ignored; never true Linux: Settable
1000	Sticky bit	Windows: Ignored; never true Linux: Settable
0400	Read by owner	Windows: Ignored; always true Linux: Settable
0200	Write by owner	Settable
0100	Execute by owner	Windows: Ignored; based on file name extension Linux: Settable
0040, 0020, 0010	Read, Write, Execute by group	Windows: Ignored; assumes owner permissions

Permission bit	Description	Action
		Linux: Settable
0004, 0002, 0001	Read, Write, Execute by others	Windows: Ignored; assumes owner permissions
		Linux: Settable

The following regular expression represents a symbolic mode:

```
[ugoa]*[+-=] [rwxXst]*
```

On Windows* systems, "[ugoa]*" is ignored. On Linux* systems, a combination of the letters "ugoa" control which users' access to the file will be changed:

u	The user who owns the file
g	Other users in the group that owns the file
o	Other users not in the group that owns the file
a	All users

"[+ - =]" indicates the operation to carry out:

+	Add the permission
-	Remove the permission
=	Absolutely set the permission

"[rwxXst]*" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux systems, all letters are significant.

Results

The result type is INTEGER(4). It is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The specified file was not found.
- EINVAL: The mode argument is invalid.
- EPERM: Permission denied; the file's mode cannot be changed.

Example

```
USE IFPORT
integer(4) I,Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (i) then
   ISTATUS = CHMOD ("datafile.txt", "[+w]")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, i
```

SETFILEACCESSQQ

CLASS

Statement: *Declares a polymorphic object. It takes one of the following forms:*

Syntax

```
CLASS (name) att-list :: v-list

CLASS (*) att-list :: v-list
```

name — Is the name of the extensible derived data type.

att-list — Is one or more attribute specifiers. These are the same attribute specifiers allowed for a derived-type TYPE statement.

v-list — Is the name of one or more data objects or functions. The name can optionally be followed by any of the following:

- An array specification, if the object is an array.

  In a function declaration, an array must be a deferred-shape array if it has the POINTER attribute; otherwise, it must be an explicit-shape array.
- A character length, if the object is of type character.
- A coarray specification, if the object is a coarray.
- A constant expression preceded by an = or, for pointer objects, => NULL( ).

Description

A polymorphic object can have differing types during program execution.

The type of the object at a particular point during execution of a program is its dynamic type.

The declared type of a data entity is the type that it is declared to have, either explicitly or implicitly.

If CLASS (*) is specified, it denotes an unlimited polymorphic object. An unlimited polymorphic entity is not declared to have a type. It is not considered to have the same declared type as any other entity, including another unlimited polymorphic entity.

An entity declared with the CLASS keyword must be a dummy argument or have the ALLOCATABLE or POINTER attribute.

A polymorphic entity that is not an unlimited polymorphic entity is type compatible with entities of the same declared type or any of its extensions. Even though an unlimited polymorphic entity is not considered to have a declared type, it is type compatible with all entities. An entity is said to be type compatible with a type if it is type compatible with entities of that type.

A polymorphic allocatable object can be allocated to be of any type with which it is type compatible.

During program execution, a polymorphic pointer or dummy argument can be associated with objects with which it is type compatible.

TYPE Statement (Derived Types)

CLEARSTATUSFPQQ

Portability Subroutine: *Clears the exception flags in the floating-point processor status word.*

Module

USE IFPORT

Syntax

```
CALL CLEARSTATUSFPQQ()
```

Description

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see *Floating-Point Operations*: Floating-Point Environment.

Example

```
! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a
! floating-point exception has occurred.
! So, build this console application with the default
! floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows)
! or -O0 (Linux) to get the correct results.
!
! PROGRAM CLEARFP

  USE IFPORT

  REAL*4 A,B,C
  INTEGER*2 STS

  A = 2.0E0
  B = 0.0E0

! Poll and display initial floating point status
  CALL GETSTATUSFPQQ(STS)
  WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS

! Cause a divide-by-zero exception
! Poll and display the new floating-point status
  C = A/B
  CALL GETSTATUSFPQQ(STS)
  WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS

! If a divide by zero error occurred, clear the floating-point
! status register so future exceptions can be detected.
  IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
    CALL CLEARSTATUSFPQQ()
    CALL GETSTATUSFPQQ(STS)
    WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
  ENDIF

  END
```

This program is available in the online samples.

CLOCK

Portability Function: *Converts a system time into an 8-character ASCII string.*

Module

USE IFPORT

Syntax

```
result = CLOCK( )
```

Results

The result type is character with a length of 8. The result is the current time in the form hh:mm:ss, using a 24-hour clock.

Example

```
USE IFPORT
character(8) whatimeisit
whatimeisit = CLOCK ()
print *, 'The current time is ',whatimeisit
```

See Also

DATE_AND_TIME

CLOCKX

Portability Subroutine: *Returns the processor clock in units of microseconds.*

Module

USE IFPORT

Syntax

CALL CLOCKX (*clock*)

clock	(Input) REAL(8). The current time.

On Windows systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

CLOSE

Statement: *Disconnects a file from a unit.*

Syntax

CLOSE ([UNIT=] *io-unit*[, {STATUS | DISPOSE | DISP} = *p*] [, ERR= *label*] [, IOMSG=*msg-var*] [, IOSTAT=*i-var*])

io-unit	(Input) an external unit specifier.
p	(Input) a scalar default character expression indicating the status of the file after it is closed. It has one of the following values:

- 'KEEP' or 'SAVE' - Retains the file after the unit closes.
- 'DELETE' - Deletes the file after the unit closes (unless OPEN(READONLY) is in effect).
- 'PRINT' - Submits the file to the line print spooler, then retains it (sequential files only).
- 'PRINT/DELETE' - Submits the file to the line print spooler, then deletes it (sequential files only).
- 'SUBMIT' - Forks a process to execute the file.
- 'SUBMIT/DELETE' - Forks a process to execute the file, then deletes the file after the fork is completed.

The default is 'DELETE' for user windows in Windows* QuickWin applications and for scratch files. For all other files, the default is 'KEEP'.

Scratch files are temporary and are always deleted upon normal program termination; specifying STATUS='KEEP' for scratch files causes a runtime error.

For user windows in Windows* QuickWin applications, STATUS='KEEP' causes the child window to remain on the screen even after the unit closes. The default status is 'DELETE', which removes the child window from the screen.

label — Is the label of the branch target statement that receives control if an error occurs.

msg-var — (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var — (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The CLOSE statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The status specified in the CLOSE statement supersedes the status specified in the OPEN statement, except that a file opened as a scratch file cannot be saved, printed, or submitted, and a file opened for read-only access cannot be deleted.

If a CLOSE statement is specified for a unit that is not open, it has no effect.

You do not need to explicitly close open files. Normal program termination closes each file according to its default status. The CLOSE statement does not have to appear in the same program unit that opened the file.

Closing unit 0 automatically reconnects unit 0 to the keyboard and screen. Closing units 5 and 6 automatically reconnects those units to the keyboard or screen, respectively. Closing the asterisk (*) unit causes a compile-time error. In Windows QuickWin applications, use CLOSE with unit 0, 5, or 6 to close the default window. If all of these units have been detached from the console (through an explicit OPEN), you must close one of these units beforehand to reestablish its connection with the console. You can then close the reconnect unit to close the default window.

If a parameter of the CLOSE statement is an expression that calls a function, that function must not cause an I/O operation or the EOF intrinsic function to be executed, because the results are unpredictable.

NOTE
You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the runtime library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures: USEROPEN Specifier.

Example

```
!    Close and discard file:
     CLOSE (7, STATUS = 'DELETE')
```

Consider the following statement:

```
  CLOSE (UNIT=J, STATUS='DELETE', ERR=99)
```

This statement closes the file connected to unit J and deletes it. If an error occurs, control is transferred to the statement labeled 99.

Branch Specifiers

CMPLX

Elemental Intrinsic Function (Specific): *Converts the argument to complex type. This function cannot be passed as an actual argument.*

Syntax

This intrinsic function can take one of the following forms:

`result = CMPLX (x [,kind])`

x	(Input) Must be of type complex.
kind	(Input; optional) Must be a scalar integer constant expression.

or

`result = CMPLX (x [,y ,kind])`

x	(Input) Must be of type integer, real, or a binary, octal, or hexadecimal literal constant.
y	(Input; optional) Must be of type integer, real, or a binary, octal, or hexadecimal literal constant.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is complex. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of default real type.

If *x* is type complex, *y* must not be specified, and the result value is CMPLX (REAL (*x*), AIMAG (*x*)), with default kind if *kind* is not present, otherwise with the kind type as specified by *kind*.

If *x* is present and not of complex type, and *y* is not present, *x* is converted into the real part of the result value and zero is assigned to the imaginary part.

If *x* and *y* are present, the complex value is produced by converting the *x* into the real part of the value, and converting the *y* into the imaginary part.

CMPLX (*x*, *y*, *kind*) has the complex value whose real part is REAL (*x*, *kind*) and whose imaginary part is REAL (*y*, *kind*).

The setting of compiler options specifying real size can affect this function.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

NOTE
The result values of CMPLX are defined by references to the intrinsic function REAL with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to CMPLX is the same as for the intrinsic function REAL.

Example

CMPLX (-3) has the value (-3.0, 0.0).

CMPLX (4.1, 2.3) has the value (4.1, 2.3).

The following shows another example:

```
COMPLEX z1, z2
COMPLEX(8) z3
z1 = CMPLX(3)      ! returns the value 3.0 + i 0.0
z2 = CMPLX(3,4)    ! returns the value 3.0 + i 4.0
z3 = CMPLX(3,4,8) ! returns a COMPLEX(8) value 3.0D0 + i 4.0D0
```

CO_BROADCAST

Collective Intrinsic Subroutine (Generic):
Broadcasts a value to other images.

Syntax

```
CALL CO_BROADCAST (a, source_image [, stat, errmsg])
```

a	(Input; output) Must have the same shape, dynamic type, and type parameter values in corresponding references across all participating images. It cannot be a coindexed object. If an error occurs, it becomes undefined. Otherwise, *a* becomes defined as if by intrinsic assignment with the value *a* on image *source_image* on all images of the current team.

source_image	(Input) Must be a scalar integer. The value of *source_image* must the value of an image index of an image on the current team. Its value must be the same in corresponding references on all images participating in the collective operation.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Collective Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.
errmsg	(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of *errmsg* is described in *Overview of Collective Subroutines*.

Example

Consider the following:

```
CALL CO_BROADCAST (R, 5)
```

If R is a four-element array defined with the value [10, 20, 30, 40] on image 5 when the subroutine is referenced, R becomes defined with the value [10, 20, 30, 40] on all images of the current team if no error condition occurs during the subroutine reference.

Overview of Collective Subroutines

CO_MAX

Collective Intrinsic Subroutine (Generic):
Calculates the maximum value across images.

Syntax

```
CALL CO_MAX (a [, result_image, stat, errmsg])
```

a	(Input; output) Must be of type real, integer, or charater, and have the same shape, type, and type parameter values in corresponding references across all images of the current team. It cannot be a coindexed object. If it is scalar, the computed value is the maximum value of *a* in all corresponding references. If it is an array, each element of the computed value is equal to the maximum value of the corresponding element of *a* in all corresponding references. If no error occurs, the computed value is assigned to *a* on all images of the current team if *result_image* is not present, or on the executing image if the executing image is the image identified by *result_image*. Otherwise, *a* becomes undefined.
result_image	(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If *result_image* is not present, it cannot be present in any corresponding reference.

stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Collective Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.
errmsg	(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of *errmsg* is described in *Overview of Collective Subroutines*.

Example

Consider the following:

```
CALL CO_MAX (Z)
```

If there are two images and Z is a four-element array defined with the value [5, 10, 20, 15] on image one and [10, 15, 20, 5] on image two when the subroutine is referenced, Z becomes defined with the value [10, 15, 20, 15] on both images if no error occurs during the subroutine reference, and CALL CO_MAX (Z, 2) causes Z on image to become defined with the values [10, 15, 20, 15] on image 2; Z on image 1 becomes undefined.

See Also

Overview of Collective Subroutines

CO_MIN

Collective Intrinsic Subroutine (Generic):
Calculates the minimum value across images.

Syntax

CALL CO_MIN (*a* [, *result_image*, *stat*, *errmsg*])

a	(Input; output) Must be of type real, integer, or charater, and have the same shape, type, and type parameter values in corresponding references across all images of the current team. It cannot be a coindexed object. If it is scalar, the computed value is the minimum value of *a* in all corresponding references. If it is an array, each element of the computed value is equal to the maximum value of the corresponding element of *a* in all corresponding references. If no error occurs, the computed value is assigned to *a* on all images of the current team if *result_image* is not present, or on the executing image if the executing image is the image identified by *result_image*. Otherwise, *a* becomes undefined.
result_image	(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If *result_image* is not present, it cannot be present in any corresponding reference.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Collective Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

errmsg (Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of *errmsg* is described in *Overview of Collective Subroutines*.

Example

Consider the following:

```
CALL CO_MIN (Z)
```

If there are two images, and Z is a four-element array defined with the value [5, 10, 20, 15] on image one and [10, 15, 20, 5] on image two when the subroutine is referenced, Z becomes defined with the value [5, 10, 20, 5] on both images if no error occurs during the subroutine reference, and CALL CO_MIN (Z, 1) causes Z on image 1 to become defined with the value [5, 10, 20 5]; Z on image 2 becomes undefined.

See Also

Overview of Collective Subroutines

CO_REDUCE

Collective Intrinsic Subroutine (Generic):
Performs generalized reduction across images.

Syntax

```
CALL CO_REDUCE (a, operation [, result_image, stat, errmsg])
```

a (Input; output) Must be non-polymorphic, non-coindexed, with the same shape, type and type parameters in corresponding references. It may not be a coindexed object.

If *a* is scalar, the computed value is the result of the reduction of applying operation to the values of *a* in all corresponding references. If *a* is an array, each element of the computed value is equal to the result of the reduction of the reduction operation of applying operation to corresponding elements of *a* in all corresponding references.

If no error occurs, the computed value is assigned to *a* on all images of the current team if *result_image* is not present, or on the executing image if the executing image is the image identified by *result_image*. Otherwise, *a* becomes undefined.

operation Is a pure function with exactly two arguments whose result and each argument are a scalar, nonallocatable, nonpointer, nonpolymorphic data object with the same type and kind type parameters as *a*. Neither argument can be optional.

If one argument has the attribute TARGET, VOLATILE, or ASYNCHRONOUS, the other argument must have that attribute. *operation* must implement a mathematical associative operation and be the same in each corresponding reference. If operation is not commutative, the computed value may depend on the order of evaluation.

The computed value of a reduction operation over a set of values is the result of an iterative process. Each iteration evaluates operation (x, y) for x and y in that set, the removal of x and y from that set, and the addition of the result of operation (x, y) to that set. The process ends when the set has a single value, which is the computed value.

result_image	(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If *result_image* is not present, it cannot be present in any corresponding reference.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Collective Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.
errmsg	(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of *errmsg* is described in *Overview of Collective Subroutines*.

Example

The following subroutine demonstrates how CO_REDUCE can be used to create a collective version of the intrinsic function ANY.

```
SUBROUTINE CO_ANY (Z)
  LOGICAL,INTENT(INOUT) :: Z (4)
  CALL CO_REDUCE (Z, COMBINER)
  CONTAINS
    PURE FUNCTION COMBINER (OPND1, OPND2)RESULT = LOGICAL_SUM
      LOGICAL                 :: LOGICAL_SUM
      LOGICAL,INTENT(IN)      :: OPND1, OPND2
      LOGICAL_SUM = OPND1 .OR. OPND2
    END FUNCTION COMBINER
END SUBROUTINE CO_ANY
```

If the number of images is two, and Z is a four-element logical array with the value [.T., .T., .F., .F.] on image one and [.T., .F., .T., .F.] on image two, CALL CO_REDUCE (Z, COMBINER) causes the value of array Z to become defined with the value of [.T., .T., .T., .F.] on both images if no error occurs during the reference.

See Also

Overview of Collective Subroutines

CO_SUM

Collective Intrinsic Subroutine (Generic):
Performs a sum reduction across images.

Syntax

```
CALL CO_SUM (a [, result_image, stat, errmsg])
```

a	(Input; output) Must be of type real, integer, or complex, and have the same shape, type, and type parameter values in corresponding references. It may not be a coindexed object. If it is scalar, the computed value is the sum of the values of *a* in all corresponding references. If it as an array, each element of the computed value is equal to the sum of the values of the corresponding element of *a* in all corresponding references. If no error occurs, the computed value is assigned to *a* on all images of the current team if *result_image* is not present, or on the executing image if the executing image is the image identified by *result_image*. Otherwise, *a* becomes undefined.

result_image	(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If *result_image* is not present, it may not be present in any corresponding reference.
stat	(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Collective Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.
errmsg	(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of errmsg is described in *Overview of Collective Subroutines*.

Example

Consider the following:

```
CALL CO_SUM (Z, 2)
```

If the number of images is two and if Z is a four-element array defined with the value [5, 10, 20, 15] on image one and [10, 15, 20, 5] on image two when the procedure is referenced, Z becomes defined with the value [15, 25, 40, 20] on image two and undefined on image one if no error occurs during the subroutine reference, and CALL CO_SUM (Z) causes Z on both images to become defined with the value [15, 25, 40, 20].

Overview of Collective Subroutines

CODE_ALIGN

General Compiler Directive: *Specifies the byte alignment for a loop.*

Syntax

```
!DIR$ CODE_ALIGN [:n]
```

n	(Optional) A positive integer constant expression indicating the number of bytes for the minimum alignment boundary. Its value must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. If you specify 1 for *n*, no alignment is performed. If you do not specify *n*, the default alignment is 16 bytes.

This directive must precede the loop or block of code to be aligned.

If code is compiled with the `-falign-loops=m` (Linux*) or `/Qalign-loops:m` (Windows*) option and a "CODE_ALIGN:n" directive precedes a loop, the loop is aligned on a MAX (m, n) byte boundary.

If a procedure has the "CODE_ALIGN:k" attribute and a "CODE_ALIGN:n" directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

Example

Consider the following code fragment in file `test_code_align.f90`:

```
!DIR$ CODE_ALIGN
DO J = 1, N
…
END DO
```

Compiling `test_code_align.f90` aligns the code that begins the DO J loop on a (default) 16-byte boundary. If you do not specify the CODE_ALIGN directive, the alignment of the loop is implementation-dependent and may change from compilation to compilation.

ATTRIBUTES CODE_ALIGN directive

CODIMENSION

Statement and Attribute: *Specifies that an entity is a coarray, and specifies its corank and cobounds, if any.*

Syntax

The CODIMENSION attribute can be specified in a type declaration statement or a CODIMENSION statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] CODIMENSION [*coarray-spec*] :: *var-list* [(*array-spec*)]...

type, [*att-ls*,] *var-list* [(*array-spec*)] [*coarray-spec*]...

Statement:

CODIMENSION [::] *var-list* [*coarray-spec*]...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
coarray-spec	Is an allocatable (deferred-coshape) coarray or an explicit-coshape coarray.
var-list	Is a list of variable names, separated by commas.

Description

In Intel® Fortran, the sum of the rank and corank of an entity must not exceed 31. The Fortran 2018 Standard allows a combined rank of up to 15.

A coarray must be a component or a variable that is not a function result.

A coarray must not be of type C_PTR or C_FUNPTR from the intrinsic module ISO_C_BINDING or of type TEAM_TYPE from the intrinsic module ISO_FORTRAN_ENV.

An entity whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar, must not be a coarray, and must not be a function result.

A coarray or an object with a coarray ultimate component must be an associate name, a dummy argument, or have the ALLOCATABLE or SAVE attribute.

A coarray must not be a dummy argument of a procedure that has a BIND attribute.

A coarray can be a derived type with pointer or allocatable components. The target of such a pointer component is always on the same image as the pointer.

Examples

Explicit-shape coarrays that are not dummy arguments must have the SAVE attribute. Because of this, automatic coarrays are not allowed. For example, coarray TASK in the following code is not valid:

```
SUBROUTINE SUBA(I,C,D)
INTEGER :: I
REAL :: C(I)[*], D(I)
REAL :: TASK(I)[*]        ! Not permitted
```

The following lines show valid examples of CODIMENSION attribute specifications:

```
REAL, CODIMENSION[3,*] :: B(:)   ! Assumed-shape coarray
REAL R(50,50)[0:5,*]             ! Explicit-shape coarray
REAL, CODIMENSION[*] :: A        ! Scalar coarray
REAL, CODIMENSION[:],ALLOCATABLE :: C(:,:)  ! Allocatable coarray
```

COLLAPSE Clause

Parallel Directive Clause: *Specifies how many loops are associated with a loop construct.*

Syntax

`COLLAPSE (n)`

n

Must be a constant positive scalar integer expression.

If *n* is greater than one, the iterations of all associated loops are collapsed into one larger iteration, which is then divided according to the SCHEDULE clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration. The associated loops must be perfectly nested, that is, there must be no intervening code or any OpenMP* directive between any two loops.

The iteration count for each associated loop is computed before entry to the outermost loop. If execution of any associated loop changes any of the values used to compute any of the iteration counts, then the behavior is unspecified. The integer kind used to compute the iteration count for the collapsed loop is implementation defined.

If COLLAPSE is not specified, the only loop that is associated with the loop construct is the one that immediately follows the construct.

At most one COLLAPSE clause can appear in a directive that allows the clause.

See Nested DO Constructs for restrictions on perfectly nested loops using COLLAPSE.

If more than one loop is associated with a TASKLOOP construct, then the iterations of all associated loops are collapsed into one larger iteration space that is then divided according to the specifications in the GRAINSIZE and NUM_TASKS clauses. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

COMMAND_ARGUMENT_COUNT

Inquiry Intrinsic Function (Generic): *Returns the number of command arguments.*

Syntax

```
result = COMMAND_ARGUMENT_COUNT ()
```

Results

The result is a scalar of type default integer. The result value is equal to the number of command arguments available. If there are no command arguments available, the result is 0. The command name does not count as one of the command arguments.

Example

Consider the following:

```
program echo_command_line
integer i, cnt, len, status
character c*30, b*100

call get_command (b, len, status)
if (status .ne. 0) then
   write (*,*) 'get_command failed with status = ', status
   stop
end if
write (*,*) 'command line = ', b (1:len)

call get_command_argument (0, c, len, status)
if (status .ne. 0) then
   write (*,*) 'Getting command name failed with status = ', status
   stop
end if
write (*,*) 'command name = ', c (1:len)

cnt = command_argument_count ()
write (*,*) 'number of command arguments = ', cnt

do i = 1, cnt
   call get_command_argument (i, c, len, status)
   if (status .ne. 0) then
     write (*,*) 'get_command_argument failed: status = ', status, ' arg = ', i
     stop
   end if
   write (*,*) 'command arg ', i, ' = ', c (1:len)
end do

write (*,*) 'command line processed'
end
```

If the above program is invoked with the command line " `echo_command_line.exe -o 42 -a hello b`", the following is displayed:

```
command line = echo_command_line.exe -o 42 -a hello b
command name = echo_command_line.exe
number of command arguments = 5
command arg 1 = -o
command arg 2= 42
command arg 3 = -a
command arg 4 = hello
command arg 5 = b
command line processed
```

COMMITQQ

Runtime Function: *Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file's physical device.*

Module

USE IFCORE

Syntax

```
result = COMMITQQ (unit)
```

unit	(Input) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

Results

The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initally written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.

COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

Example

```
USE IFCORE
INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff
OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')
DO WHILE (.TRUE.)
  WRITE (*, '(A, \)') 'Enter some data (Hit RETURN to &
                       exit): '
  len = GETSTRQQ (stuff)
  IF (len .EQ. 0) EXIT
  WRITE (unit, *) stuff
  IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
END DO
CLOSE (unit)
END
```

COMMON

Statement: *Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items. COMMON is an obsolescent language feature in Standard Fortran.*

Syntax

COMMON [/[*cname*]/] *var-list*[[,] /[*cname*]/ *var-list*]...

cname	(Optional) Is the name of the common block. The name can be omitted for blank common (//).
var-list	Is a list of variable names, separated by commas. The variable must not be a dummy argument, allocatable array, automatic object, function, function result, a variable with the BIND attribute,or entry to a procedure. It must not have the PARAMETER attribute. If an object of derived type is specified, it must be a sequence type or a type with the BIND attribute.

Description

Common blocks can be named or unnamed (a *blank common*).

A common block is a global entity, and must not have the same name as any other global entity in the program, such as a subroutine or function.

Any common block name (or blank common) can appear more than once in one or more COMMON statements in a program unit. The list following each successive appearance of the same common block name is treated as a continuation of the list for the block associated with that name. Consider the following COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin
COMMON /     / shepard, grissom, carpenter
COMMON /glenn/ borman, anders
COMMON /young/ mcdivitt, white, conrad
COMMON schirra, cooper
```

They are equivalent to these COMMON statements:

```
COMMON /glenn/ lovell, armstrong, aldrin, borman, anders
COMMON         shepard, grissom, carpenter, schirra, cooper
COMMON /young/ mcdivitt, white, conrad
```

A variable can appear in only one common block within a scoping unit.

A common block object must *not* be one of the following:

- A dummy argument
- A result variable
- An allocatable variable
- A derived-type object with an ultimate component that is allocatable
- A procedure pointer

- An automatic object
- A variable with the BIND attribute
- An unlimited polymorphic pointer
- A coarray

If an array is specified, it can be followed by an explicit-shape array specification, each bound of which must be a constant specification expression. Such an array must not have the POINTER attribute.

A pointer can only be associated with pointers of the same type and kind parameters, and rank.

An object with the TARGET attribute can only be associated with another object with the TARGET attribute and the same type and kind parameters.

A nonpointer can only be associated with another nonpointer, but association depends on their types, as follows:

Type of Variable	Type of Associated Variable
Intrinsic numeric [1]or numeric sequence [2]	Can be of any of these types
Default character or character sequence [2]	Can be of either of these types
Any other intrinsic type	Must have the same type and kind parameters
Any other sequence type	Must have the same type

[1]Default integer, default real, double precision real, default complex, double complex, or default logical.

[2]If an object of numeric sequence or character sequence type appears in a common block, it is as if the individual components were enumerated directly in the common list.

So, variables can be associated if they are of different numeric type. For example, the following is valid:

```
INTEGER A(20)
REAL Y(20)
COMMON /QUANTA/ A, Y
```

When common blocks from different program units have the same name, they share the same storage area when the units are combined into an executable program.

Entities are assigned storage in common blocks on a one-for-one basis. So, the data type of entities assigned by a COMMON statement in one program unit should agree with the data type of entities placed in a common block by another program unit. For example:

Program Unit A	Program Unit B
`COMMON CENTS`	`INTEGER(2) MONEY`
`...`	`COMMON MONEY`
	`...`

When these program units are combined into an executable program, incorrect results can occur if the 2-byte integer variable MONEY is made to correspond to the lower-addressed two bytes of the real variable CENTS.

Named common blocks must be declared to have the same size in each program unit. Blank common can have different lengths in different program units.

NOTE
If a common block is initialized by a DATA statement, the module containing the initialization must declare the common block to be its maximum defined length.

This limitation does not apply if you compile all source modules together.

Example

```
PROGRAM MyProg
COMMON i, j, x, k(10)
COMMON /mycom/ a(3)
...
END
SUBROUTINE MySub
COMMON pe, mn, z, idum(10)
COMMON /mycom/ a(3)
...
END
```

In the following example, the COMMON statement in the main program puts HEAT and X in blank common, and KILO and Q in a named common block, BLK1:

Main Program	Subprogram
COMMON HEAT,X /BLK1/KILO,Q	SUBROUTINE FIGURE
. . .	COMMON /BLK1/LIMA,R / /ALFA,BET
	. . .
CALL FIGURE	
. . .	RETURN
	END

The COMMON statement in the subroutine makes ALFA and BET share the same storage location as HEAT and X in blank common. It makes LIMA and R share the same storage location as KILO and Q in BLK1.

The following example shows how a COMMON statement can be used to declare arrays:

```
COMMON / MIXED / SPOTTED(100), STRIPED(50,50)
```

The following example shows a valid association between subroutines in different program units. The object lists agree in number, type, and kind of data objects:

```
SUBROUTINE unit1
REAL(8)      x(5)
INTEGER      J
CHARACTER    str*12
TYPE(member) club(50)
COMMON / blocka / x, j, str, club
...
SUBROUTINE unit2
REAL(8)      z(5)
INTEGER      m
CHARACTER    chr*12
```

```
TYPE(member) myclub(50)
COMMON / blocka / z, m, chr, myclub
...
```

COMPILER_OPTIONS

Module Intrinsic Inquiry Function: *Returns a string containing the compiler options that were used for compilation.*

Module

USE ISO_FORTRAN_ENV

Syntax

`result = COMPILER_OPTIONS( )`

Results

The result is a scalar of type default character of processor-defined length.

The return value is a list of the compiler options that were used for compilation.

Example

Consider the following file named `t.f90`:

```
use ISO_FORTRAN_ENV
character (len = :), allocatable :: res
res = compiler_options ()
print *, "len of res is: ", len (res)
print "('<<', A, '>>')", res
deallocate (res)
end
```

The following is the output:

Linux

```
Lin$ ifx -o t.out -warn alignments -check bounds t.f90
Lin$ t.out
 len of res is:           40
<<-o t.out -warn alignments -check bounds >>
```

Windows

```
Win>ifx /o t.out /warn:alignments /check:bounds t.f90
Intel(R) Fortran Compiler for applications running on Intel(R) 64, Version 2024.1.0 Build
20240103

ISO_FORTRAN_ENV Module

COMPILER_VERSION

Module Intrinsic Inquiry Function: *Returns a string containing the name and version number of the compiler used for compilation.*

Module

USE ISO_FORTRAN_ENV

Syntax

```
result = COMPILER_VERSION( )
```

Results

The result is a scalar of type default character of processor-defined length.

The return value contains the name and version number of the compiler used for compilation.

Example

Consider the following file named `t.f90`:

```
use ISO_FORTRAN_ENV

character (len = :), allocatable :: res

res = compiler_version ()
print *, "len of res is: ", len (res)
print "('<<', A, '>>')", res

deallocate (res)
end
```

The following is the output:

Linux

```
Lin$ ifx -o t.out -warn alignments -check bounds t.f90
Lin$ t.out
 len of res is:           98
<<Intel(R) Fortran Compiler for applications running on Intel(R) 64, Version 2024.1.0 Build
20240125>>
```

Windows

ISO_FORTRAN_ENV Module

COMPLEX Statement

Statement: *Specifies the COMPLEX data type.*

Syntax

```
COMPLEX

COMPLEX([KIND=] n)

COMPLEX*s

DOUBLE COMPLEX
```

n	Is kind 4, 8, or 16.
s	Is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

DOUBLE COMPLEX is COMPLEX(8). No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

Example

```
COMPLEX ch
COMPLEX (KIND=4),PRIVATE :: zz, yy   !equivalent to COMPLEX*8 zz, yy
COMPLEX(8) ax, by        !equivalent to COMPLEX*16 ax, by
COMPLEX (kind(4)) y(10)
complex (kind=8)  x, z(10)
```

Data Types, Constants, and Variables

COMPLINT, COMPLREAL, COMPLLOG

Portability Functions: *Return a BIT-WISE complement or logical .NOT. of the argument.*

Module

USE IFPORT

Syntax

```
result = COMPLINT (intval)
result = COMPREAL (realval)
result = COMPLLOG (logval)
```

intval	(Input) INTEGER(4).
realval	(Input) REAL(4).
logval	(Input) LOGICAL(4).

Results

The result is INTEGER(4) for COMPLINT, REAL(4) for COMPLREAL and LOGICAL(4) for COMPLLOG with a value that is the bitwise complement of the argument.

CONJG

Elemental Intrinsic Function (Generic): *Calculates the conjugate of a complex number.*

Syntax

```
result = CONJG (z)
```

z	(Input) Must be of type complex.

Results

The result type and kind are the same as *z*. If *z* has the value (x, y), the result has the value (x, -y).

Specific Name	Argument Type	Result Type
CONJG	COMPLEX(4)	COMPLEX(4)
DCONJG	COMPLEX(8)	COMPLEX(8)
QCONJG	COMPLEX(16)	COMPLEX(16)

Example

CONJG ((2.0, 3.0)) has the value (2.0, -3.0).

CONJG ((1.0, -4.2)) has the value (1.0, 4.2).

The following shows another example:

```
COMPLEX z1
COMPLEX(8) z2
z1 = CONJG((3.0, 5.6))       ! returns (3.0, -5.6)
z2 = DCONJG((3.0D0, 5.6D0))  ! returns (3.0D0, -5.6D0)
```

AIMAG

CONTAINS

Statement: *Separates the body of a main program, module, submodule, or external subprogram from any internal or module procedures it may contain, or it introduces the type-bound procedure part of a derived-type definition. It is not executable.*

Syntax

```
CONTAINS
```

Any number of internal procedures can follow a CONTAINS statement, but a CONTAINS statement cannot appear in the internal procedures themselves.

An empty CONTAINS section is allowed.

Example

```
PROGRAM OUTER
   REAL, DIMENSION(10) :: A
   . . .
   CALL INNER (A)
CONTAINS
   SUBROUTINE INNER (B)
   REAL, DIMENSION(10) :: B
   . . .
   END SUBROUTINE INNER
END PROGRAM OUTER
```

Modules and Module Procedures
Main Program

CONTIGUOUS

Statement and Attribute: *Specifies that the target of a pointer or an assumed-sized array is contiguous.*

Syntax

The CONTIGUOUS attribute can be specified in a type declaration statement or an CONTIGUOUS statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] CONTIGUOUS [, *att-ls*] :: *object* [, *object*] ...

Statement:

CONTIGUOUS [::] *object* [, *object*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
object	Is an assumed-shape array or an array pointer.

Description

This attribute explicitly indicates that an assumed-shape array is contiguous or that a pointer will only be associated with a contiguous object.

An entity can be contiguous even if CONTIGUOUS is not specified. An object is contiguous if it is one of the following:

- An object with the CONTIGUOUS attribute
- A nonpointer whole array that is not assumed-shape
- An assumed-shape array that is argument associated with an array that is contiguous
- An array allocated by an ALLOCATE statement
- An pointer associated with a contiguous target
- A nonzero-sized array section in which the following is true:
  - Its base object is contiguous.
  - It does not have a vector subscript.
  - The elements of the section, in array element order, are a subset of the base object elements that are consecutive in array element order.
  - If the array is of type character and a substring-range appears, the substring-range specifies all of the characters of the parent-string.
  - Only its final reference to a structure component, if any, has nonzero rank
  - It is not the real or imaginary part of an array of type complex.

An object is *not* contiguous if it is an array subobject, and all of the following are true:

- The object has two or more elements.
- The elements of the object in array element order are not consecutive in the elements of the base object.
- The object is not of type character with length zero.
- The object is not of a derived type that has no ultimate components other than zero-sized arrays and characters with length zero.

The CONTIGUOUS attribute can make it easier to enable optimizations that rely on the memory layout of an object occupying a contiguous block of memory.

An array variable is considered to be simply contiguous if and only if it is a simply contiguous array designator, or a reference to a function that returns a pointer that has the CONTIGUOUS attribute. An array designator is simply contiguous if and only if it is one of the following:

- An object name that has the CONTIGUOUS attribute
- An object that is not assumed-rank, assumed shape, or a pointer
- A component of a derived type whose final part-name is an array, and is either not a pointer, or it has the CONTIGUOUS attribute
- An array section that complies with these rules:
  - It does not have a substring range
  - It is not a complex-part designator
  - Its final part-ref has a nonzero rank
  - Its rightmost part-name has the CONTIGUOUS attribute or is neither assumed-shape or a pointer
  - It does not have a section-subscript list, or if it does, it has a section-subscript list that specifies a simply contiguous section

A section-subscript list specifies a simply contiguous array section if and only if it does not have a vector subscript and the following is true:

- All but the last subscript-triplets are a colon (the last can also be a colon)
- The last subscript-triplet does not specify a stride
- No subscript triplet is preceded by a section-subscript that is simply a subscript

Examples

The following examples show valid CONTIGUOUS statements:

```
REAL, CONTIGUOUS, DIMENSION(:,:) :: A
REAL, POINTER, CONTIGUOUS :: MY_POINTER(:)
```

See Also

Type Declarations
Compatible attributes

CONTINUE

Statement: *Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.*

Syntax

```
CONTINUE
```

The statement by itself does nothing and has no effect on program results or execution sequence.

Example

The following example shows a CONTINUE statement:

```
    DO 150 I = 1,40
40  Y = Y + 1
    Z = COS(Y)
    PRINT *, Z
    IF (Y .LT. 30) GO TO 150
    GO TO 40
150 CONTINUE
```

The following shows another example:

```
     DIMENSION narray(10)
     DO 100 n = 1, 10
     narray(n) = 120
100  CONTINUE
```

END DO
DO
Execution Control

COPYIN Clause

Parallel Directive Clause: *Specifies that the data in the primary thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.*

Syntax

```
COPYIN (list)
```

list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The COPYIN clause applies only to common blocks declared as THREADPRIVATE.

You do not need to specify the whole THREADPRIVATE common block, you can specify named variables within the common block.

COPYPRIVATE Clause

Parallel Directive Clause: *Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.*

Syntax

```
COPYPRIVATE (list)
```

list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables in the list must not appear in a PRIVATE or FIRSTPRIVATE clause for the SINGLE directive construct. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a COPYPRIVATE clause.

If the directive is encountered in the dynamic extent of a parallel region, variables in the list must be private in the enclosing context.

If a common block is specified, it must be declared as THREADPRIVATE; the effect is the same as if the variable names in its common block object list were specified.

The effect of the COPYPRIVATE clause on the variables in its list occurs after the execution of the code enclosed within the SINGLE construct, and before any threads in the team have left the barrier at the end of the construct.

NOTE
This construct is not supported within a TARGET or a DECLARE TARGET region if the target hardware is spir64.

COS

Elemental Intrinsic Function (Generic): *Produces the cosine of an argument in radians.*

Syntax

```
result = COS (x)
```

x	(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

Results

The result type and kind are the same as *x*.

If *x* is of type real, the result is a value in radians.

If *x* is of type complex, the real part of the result is a value in radians.

Specific Name	Argument Type	Result Type
COS	REAL(4)	REAL(4)
DCOS	REAL(8)	REAL(8)
QCOS	REAL(16)	REAL(16)
CCOS [1]	COMPLEX(4)	COMPLEX(4)
CDCOS [2]	COMPLEX(8)	COMPLEX(8)
CQCOS	COMPLEX(16)	COMPLEX(16)

[1]The setting of compiler options specifying real size can affect CCOS.

[2]This function can also be specified as ZCOS.

Example

COS (2.0) has the value -0.4161468.

COS (0.567745) has the value 0.8431157.

COSD

Elemental Intrinsic Function (Generic): *Produces the cosine of x in degrees.*

Syntax

```
result = COSD (x)
```

x (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

Results

The result type and kind are the same as *x*.

Specific Name	Argument Type	Result Type
COSD	REAL(4)	REAL(4)
DCOSD	REAL(8)	REAL(8)
QCOSD	REAL(16)	REAL(16)

Example

COSD (2.0) has the value 0.9993908.

COSD (30.4) has the value 0.8625137.

COSH

Elemental Intrinsic Function (Generic): *Produces a hyperbolic cosine.*

Syntax

```
result = COSH (x)
```

x	(Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*.

If *x* is of type complex, the imaginary part of the result is in radians.

Specific Name	Argument Type	Result Type
COSH	REAL(4)	REAL(4)
DCOSH	REAL(8)	REAL(8)
QCOSH	REAL(16)	REAL(16)

Example

COSH (2.0) has the value 3.762196.

COSH (0.65893) has the value 1.225064.

COSHAPE

Inquiry Intrinsic Function (Generic): *Returns the sizes of codimensions of a coarray.*

Syntax

```
result = COSHAPE (coarray [, kind])
```

coarray	(Input) Is a coarray. It may be of any data type. It must not be an unallocated allocatable coarray.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is an integer array of rank one whose size is equal to the corank of *coarray*. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer.

The result has a value whose *i*th element is equal to the size of the *i*th codimension of *coarray* as provided by UCOBOUND(*coarray*, *i*) − LCOBOUND(*coarray*, *i*) + 1.

The setting of compiler options specifying integer size can affect this function.

Example

Consider the following coarray declaration:

```
REAL :: X (10, 20) [10, -1:8, 0:*]
```

It NUM_IMAGES() is 200, it has these properties:

- RANK (X) == 2
- corank of X == 3
- SHAPE (X) == [10,20]
- COSHAPE (X) == [10,10,2]
- LCOBOUND (X) == [1, -1, 0]

- UCOBOUND (X) == [10, 8, 1]

UCOBOUND

COTAN

Elemental Intrinsic Function (Generic): *Produces the cotangent of x in radians.*

Syntax

```
result = COTAN (x)
```

x	(Input) Must be of type real; it cannot be zero. It must be in radians and is treated as modulo 2*pi.

Results

The result type and kind are the same as *x*.

Specific Name	Argument Type	Result Type
COTAN	REAL(4)	REAL(4)
DCOTAN	REAL(8)	REAL(8)
QCOTAN	REAL(16)	REAL(16)

Example

COTAN (2.0) has the value -4.576575E-01.

COTAN (0.6) has the value 1.461696.

COTAND

Elemental Intrinsic Function (Generic): *Produces the cotangent of x in degrees.*

Syntax

```
result = COTAND (x)
```

x	(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

Results

The result type and kind are the same as *x*.

Specific Name	Argument Type	Result Type
COTAND	REAL(4)	REAL(4)
DCOTAND	REAL(8)	REAL(8)

Specific Name	Argument Type	Result Type
QCOTAND	REAL(16)	REAL(16)

Example

COTAND (2.0) has the value 0.2863625E+02.

COTAND (0.6) has the value 0.9548947E+02.

COUNT

Transformational Intrinsic Function (Generic):
Counts the number of true elements in an entire array or in a specified dimension of an array.

Syntax

```
result = COUNT (mask[,dim][, kind])
```

mask	(Input) Must be a logical array.
dim	(Input; optional) Must be a scalar integer expression with a value in the range 1 to n, where *n* is the rank of *mask*.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is an array or a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is a scalar if *dim* is omitted or *mask* has rank one. A scalar result has a value equal to the number of true elements of *mask*. If *mask* has size zero, the result is zero.

An array result has a rank that is one less than *mask*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2,..., d_n) is the shape of *mask*.

Each element in an array result equals the number of elements that are true in the one dimensional array defined by *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n).

Example

COUNT ((/.TRUE., .FALSE., .TRUE./)) has the value 2 because two elements are true.

COUNT ((/.TRUE., .TRUE., .TRUE./)) has the value 3 because three elements are true.

A is the array

```
 [ 1  5  7 ]
 [ 3  6  8 ]
```

and B is the array

```
 [ 0  5  7 ]
 [ 2  6  9 ].
```

COUNT (A .NE. B, DIM=1) tests to see how many elements in each column of A are not equal to the elements in the corresponding column of B. The result has the value (2, 0, 1) because:

- The first column of A and B have 2 elements that are not equal.
- The second column of A and B have 0 elements that are not equal.
- The third column of A and B have 1 element that is not equal.

COUNT (A .NE. B, DIM=2) tests to see how many elements in each row of A are not equal to the elements in the corresponding row of B. The result has the value (1, 2) because:

- The first row of A and B have 1 element that is not equal.
- The second row of A and B have 2 elements that are not equal.

The following shows another example:

```
LOGICAL mask (2, 3)
INTEGER AR1(3), AR2(2), I
mask = RESHAPE((/.TRUE., .TRUE., .FALSE., .TRUE., &
                 .FALSE., .FALSE./),(/2,3/))
!
! mask is the array   true false false
!                     true true false
AR1 = COUNT(mask,DIM=1) ! counts true elements by
                        ! column yielding [2 1 0]
AR2 = COUNT(mask,DIM=2) ! counts true elements by row
                        ! yielding [1 2]
I = COUNT( mask)        ! returns 3
```

ALL

ANY

CPU_TIME

Intrinsic Subroutine (Generic): *Returns a processor-dependent approximation of the processor time in seconds. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL CPU_TIME (time)
```

time	(Output) Must be scalar and of type real.

The time returned is summed over all active threads. The result is the sum (in units of seconds) of the current process's user time and the user and system time of all its child processes, if any.

If a meaningful time cannot be returned, a processor-dependent negative value is returned.

> **NOTE**
> If you want to estimate performance or scaling of multithreaded applications, you should use intrinsic subroutine SYSTEM_CLOCK or portability function DCLOCK. Both of these routines return the elapsed time from a single clock.

Example

Consider the following:

```
REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
! task to be timed
!
CALL CPU_TIME ( time_end )
WRITE (*,*) 'Time of operation was ', time_end - time_begin, ' seconds'
```

DCLOCK

SYSTEM_CLOCK

CRITICAL Directive

OpenMP* Fortran Compiler Directive: *Restricts access to a block of code to only one thread at a time.*

Syntax

```
!$OMP CRITICAL [(name) [[,] clause]]
   loosely-structured-block
!$OMP END CRITICAL [(name)]
-or-
!$OMP CRITICAL [(name) [[,] clause]]
   strictly-structured-block
[!$OMP END CRITICAL [(name)]]
```

name	Is the name of the critical section.
clause	Is HINT (hint-expression).
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a CRITICAL construct is all threads in the contention group. Region execution is restricted to a single thread at a time among all threads in the contention group, without regard to the teams to which the threads belong.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name. All unnamed CRITICAL directives map to the same name.

A *name* is optional if HINT does not appear, or if HINT appears with a hint value of OMP_SYNC_HINT_NONE. If a name is specified in the CRITICAL directive, the same name must appear in the corresponding END CRITICAL directive. If no name appears in the CRITICAL directive, no name can appear in the corresponding END CRITICAL directive. The *hint-expression* of each CRITICAL construct with the same name specified must evaluate to the same HINT value.

Critical section names are global entities of the program. If the name specified conflicts with any other entity, the behavior of the program is undefined.

Example

The following example shows a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation is placed in a critical section.

Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, XAXIS and YAXIS, respectively:

```
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,Y)
!$OMP CRITICAL(XAXIS)
      CALL DEQUEUE(IX_NEXT, X)
```

```
!$OMP END   CRITICAL(XAXIS)
      CALL WORK(IX_NEXT, X)
!$OMP CRITICAL(YAXIS)
      CALL DEQUEUE(IY_NEXT,Y)
!$OMP END   CRITICAL(YAXIS)
      CALL WORK(IY_NEXT, Y)
!$OMP END PARALLEL
```

CRITICAL Statement

Statement: *Marks the beginning of a CRITICAL construct. A CRITICAL construct limits execution of a block to one image at a time.*

Syntax

```
[name:] CRITICAL [([STAT=stat-var] [, ERRMSG=err-var])]
   block
END CRITICAL [name]
```

name	(Optional) Is the name of the CRITICAL construct.
stat-var	Is a scalar integer variable with an exponent range of at least 4 (KIND=2 or greater).
err-var	Is a scalar default character variable.
block	Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified in a CRITICAL statement, the same name must appear in the corresponding END CRITICAL statement. If no name is specified at the beginning of a CRITICAL statement, you cannot specify one following the END CRITICAL statement. The same construct name must not be used for different named constructs in the same scoping unit.

The block of a CRITICAL construct must not contain a RETURN statement or an image control statement.

A branch within a CRITICAL construct must not have a branch target that is outside the construct. A branch to the END CRITICAL statement is permitted from within the construct.

STAT= and ERRMSG= specifiers can appear in any order. Each may appear at most once.

Execution of the CRITICAL construct is completed when execution of its block is completed. A procedure that is invoked, directly or indirectly, from a CRITICAL construct must not execute an image control statement.

If no error condition occurs during the execution of the construct, *stat-var* becomes defined with the value zero. If the image that previously entered the construct failed while executing the construct, *stat-var* becomes defined with the value STAT_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. If any other error occurs and STAT= is specified, *stat-var* becomes defined with a positive integer value other than that of STAT_FAILED_IMAGE. Otherwise, if an error occurs, error termination is initiated.

If ERRMSG= is specified and an error condition occurs during execution of the construct, *err-var* becomes defined with a descriptive message describing the nature of the error.

The processor ensures that once an image has commenced executing *block*, no other image can start executing *block* until this image has completed executing *block*. The image must not execute an image control statement during the execution of *block*. The sequence of executed statements is therefore a segment. If image S is the next to execute the construct after image N, the segment on image N precedes the segment on image S.

If more than one image executes the block of a CRITICAL construct, its execution by one image always precedes or succeeds its execution by another image. Normally no other statement ordering is needed.

Example

Consider the following example:

```
CONA: CRITICAL
  MY_COUNTER[1] = MY_COUNTER[1] + 1
END CRITICAL CONA
```

The definition of MY_COUNTER [1] by a particular image will always precede the reference to the same variable by the next image to execute the block.

The following example shows a way to share a large number of tasks among images:

```
INTEGER :: NUMBER_TASKS[*], TASK
IF (THIS_IMAGE() == 1) READ(*,*) NUMBER_TASKS
SYNC ALL
DO
   CRITICAL
      TASK = NUMBER_TASKS[1]
      NUMBER_TASKS[1] = TASK - 1
   END CRITICAL
IF (TASK > 0) THEN
ELSE
   EXIT
END IF
END DO
SYNC ALL
```

CSHIFT

Transformational Intrinsic Function (Generic):
Performs a circular shift on a rank-one array, or performs circular shifts on all the complete rank-one sections (vectors) along a given dimension of an array of rank two or greater.

Syntax

Elements shifted off one end are inserted at the other end. Different sections can be shifted by different amounts and in different directions.

`result = CSHIFT (array,shift [,dim])`

array	(Input) Array whose elements are to be shifted. It can be of any data type.

shift	(Input) The number of positions shifted. Must be a scalar integer or an array with a rank that is one less than *array*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *array*.
dim	(Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer with a value in the range 1 to n, where n is the rank of array. If *dim* is omitted, it is assumed to be 1.

Results

The result is an array with the same type and kind parameters, and shape as *array*.

If *array* has rank one, element i of the result is *array*(1 + MODULO (i + *shift*- 1, SIZE (*array*))). (The same shift is applied to each element.)

If *array* has rank greater than one, each section (s_1,s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) of the result is shifted as follows:

- By the value of *shift*, if *shift* is scalar
- According to the corresponding value in *shift*(s_1, s_2,..., s_{dim-1}, s_{dim+1},..., s_n), if *shift* is an array

The value of *shift* determines the amount and direction of the circular shift. A positive *shift* value causes a shift to the left (in rows) or up (in columns). A negative *shift* value causes a shift to the right (in rows) or down (in columns). A zero *shift* value causes no shift.

Example

V is the array (1, 2, 3, 4, 5, 6).

CSHIFT (V, SHIFT=2) shifts the elements in V circularly to the *left* by 2 positions, producing the value (3, 4, 5, 6, 1, 2). 1 and 2 are shifted off the beginning and inserted at the end.

CSHIFT (V, SHIFT= -2) shifts the elements in V circularly to the *right* by 2 positions, producing the value (5, 6, 1, 2, 3, 4). 5 and 6 are shifted off the end and inserted at the beginning.

M is the array

```
[ 1  2  3 ]
[ 4  5  6 ]
[ 7  8  9 ].
```

CSHIFT (M, SHIFT = 1, DIM = 2) produces the result

```
[ 2  3  1 ]
[ 5  6  4 ]
[ 8  9  7 ].
```

Each element in rows 1, 2, and 3 is shifted to the *left* by 1 position. The elements shifted off the beginning are inserted at the end.

CSHIFT (M, SHIFT = -1, DIM = 1) produces the result

```
[ 7  8  9 ]
[ 1  2  3 ]
[ 4  5  6 ].
```

Each element in columns 1, 2, and 3 is shifted down by 1 position. The elements shifted off the end are inserted at the beginning.

CSHIFT (M, SHIFT = (/1, -1, 0/), DIM = 2) produces the result

```
[ 2  3  1 ]
[ 6  4  5 ]
[ 7  8  9 ].
```

Each element in row 1 is shifted to the *left* by 1 position; each element in row 2 is shifted to the *right* by 1 position; no element in row 3 is shifted at all.

The following shows another example:

```
INTEGER array (3, 3), AR1(3, 3), AR2 (3, 3)
DATA array /1, 4, 7, 2, 5, 8, 3, 6, 9/
!
! array is   1 2 3
!            4 5 6
!            7 8 9
!AR1 = CSHIFT(array, 1, DIM = 1) ! shifts all columns
                                  ! by 1 yielding
                                  !         4 5 6
                                  !         7 8 9
                                  !         1 2 3
                                  !
AR2=CSHIFT(array,shift=(/-1, 1, 0/),DIM=2) ! shifts
                                  ! each row separately
                                  ! by the amount in
                                  ! shift yielding
                                  !         3 1 2
                                  !         5 6 4
                                  !         7 8 9
```

CSMG

Portability Function: *Performs an effective BIT-WISE store under mask.*

Module

USE IFPORT

Syntax

```
result = CSMG (x,y,z)
```

x, *y*, *z* (Input) INTEGER(4).

Results

The result type is INTEGER(4). The result is equal to the following expression:

```
  (x & z) | (y & ~z )
```

where "&" is a bitwise AND operation, | - bitwise OR, ~ - bitwise NOT.

The function returns the value based on the following rule: when a bit in *z* is 1, the output bit is taken from *x*. When a bit in *z* is zero, the corresponding output bit is taken from *y*.

CTIME

Portability Function: *Converts a system time into a 24-character ASCII string.*

Module

USE IFPORT

Syntax

```
result = CTIME (stime)
```

stime	(Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

Results

The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.

The value of *stime* can be determined by calling the TIME function. CTIME(TIME( )) returns the current time and date.

Example

```
USE IFPORT
character (24) systime
systime = CTIME (TIME( ))
print *, 'Current date and time is ',systime
```

See Also

DATE_AND_TIME

CYCLE

Statement: *Interrupts the current execution cycle of the innermost (or named) DO construct.*

Syntax

```
CYCLE [name]
```

name	(Optional) Is the name of the DO construct.

Description

When a CYCLE statement is executed, the following occurs:

1. The current execution cycle of the named (or innermost) DO construct is terminated.

   If a DO construct name is specified, the CYCLE statement must be within the range of that construct.
2. The iteration count (if any) is decremented by 1.
3. The DO variable (if any) is incremented by the value of the increment parameter (if any).
4. A new iteration cycle of the DO construct begins.

Any executable statements following the CYCLE statement (including a labeled terminal statement) are not executed.

A CYCLE statement can be labeled, but it cannot be used to terminate a DO construct.

Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

Example

The following example shows a CYCLE statement:

```
DO I =1, 10
  A(I) = C + D(I)
  IF (D(I) < 0) CYCLE    ! If true, the next statement is omitted
  A(I) = 0               ! from the loop and the loop is tested again.
END DO
```

The following shows another example:

```
      sample_loop: do i = 1, 5
           print *,i
             if( i .gt. 3 ) cycle sample_loop
           print *,i
           end do sample_loop
           print *,'done!'
!output:
!     1
!     1
!     2
!     2
!     3
!     3
!     4
!     5
!     done!
```

DO
DO WHILE
Execution Control

DATA

Statement: *Assigns initial values to variables before program execution.*

Syntax

`DATA` *var-list /clist/* `[[,]` *var-list /clist/*`]...`

-or-

`DATA (`*var* `=` *const* `(,` *var* `=` *const*`)...)`

var

Is a variable or implied-DO list, separated by commas. *var* cannot be a coarray, a dummy argument, accessed by use or host association, a function name, a function result name, an automatic variable, or an allocatable variable.

Subscript expressions, section expressions, and substring expressions must be constant expressions.

An implied-DO list in a DATA statement takes the following form:

(*do-list*, [*integer-type-spec* ::] *do-var*= *expr1*, *expr2*[, *expr3*])

do-list	Is a list of one or more array elements, substrings, scalar structure components, or implied-DO lists, separated by commas. Any array elements or scalar structure components must not have a constant parent.
integer-type-spec	Is INTEGER [*kind-selector*].
kind-selector	Is ([KIND=] *n*).
n	Is a constant expression whose value is 1, 2, 4, or 8.
do-var	Is the name of a scalar integer variable (the implied-DO variable). It cannot be a coarray.
expr	Implied-DO limits must be scalar constant expressions. They may contain implied-DO variables from outer nested implied-DO lists. For more details, see Iteration Loop Control.
var-list	Is a list of *var*s separated by commas.
const	Is a scalar constant expression (or name of a constant), constant structure constructor, or, for pointer objects, NULL (). If the constant is a binary, octal, or hexadecimal literal, the corresponding *var* must be of type INTEGER. In the second form of a DATA statement (DATA (*var* = *const* (, *var* = *const*) …)), *const* can also be an array constructor. A constant can be specified in the form *r**constant, where *r* is a repeat specification. *r* is a nonnegative scalar integer constant (with no kind parameter). If *r* is a named constant, it must have been declared previously in the scoping unit or made accessible through use or host association. If *r* is omitted, it is assumed to be 1.
clist	Is a list of *const*s separated by commas.

Description

A variable can be initialized only once in an executable program. A variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration which may change the implicit typing.

The number of constants in *c-list* must equal the number of variables in *var-list*. The constants are assigned to the variables in the order in which they appear (from left to right).

The following objects cannot be initialized in a DATA statement:

- A dummy argument
- A function
- A function result
- An automatic object
- An allocatable array
- A variable that is accessible by use or host association
- A variable in a named common block (unless the DATA statement is in a block data program unit)
- A variable in blank common

Except for variables in named COMMON blocks, a named variable has the SAVE attribute if any part of it is initialized in a DATA statement. You can confirm this property by specifying the variable in a SAVE statement or a type declaration statement containing the SAVE attribute.

When an unsubscripted array name appears in a DATA statement, values are assigned to every element of that array in the order of subscript progression. If the associated constant list does not contain enough values to fill the array, a warning is issued and the remaining array elements become undefined.

Array element values can be initialized in three ways: by name, by element, or by an implied-DO list (interpreted in the same way as a DO construct).

The following conversion rules and restrictions apply to variable and constant list items:

- If the constant and the variable are both of numeric type, the following conversion occurs:
  - The constant value is converted to the data type of the variable being initialized, if necessary.
  - When a binary, octal, or hexadecimal constant is assigned to a variable or array element, the number of digits that can be assigned depends on the data type of the data item. If the constant contains fewer digits than the capacity of the variable or array element, the constant is extended on the left with zeros. If the constant contains more digits than can be stored, the constant is truncated on the left. An error results if any nonzero digits are truncated.
- If the constant and the variable are both of character type, the following conversion occurs:
  - If the length of the constant is less than the length of the variable, the rightmost character positions of the variable are initialized with blank characters.
  - If the length of the constant is greater than the length of the variable, the character constant is truncated on the right.
- If the constant is of numeric type and the variable is of character type, the following restrictions apply:
  - The character variable must have a length of one character.
  - The constant must be an integer, binary, octal, or hexadecimal constant, and must have a value in the range 0 through 255.

  When the constant and variable conform to these restrictions, the variable is initialized with the character that has the ASCII code specified by the constant. (This lets you initialize a character object to any 8-bit ASCII code.)
- If the constant is a Hollerith or character constant, and the variable is a numeric variable or numeric array element, the number of characters that can be assigned depends on the data type of the data item.

  If the Hollerith or character constant contains fewer characters than the capacity of the variable or array element, the constant is extended on the right with blank characters. If the constant contains more characters than can be stored, the constant is truncated on the right.

Example

The following example shows the four ways that DATA statements can initialize array element values:

```
DIMENSION A(10,10), B(4)
DATA A/100*1.0/    ! initialization by name
DATA A(1,1), A(10,1), A(3,3) /2*2.5, 2.0/ ! initialization by element
DATA ((A(I,J), I=1,5,2), J=1,5) /15*1.0/  ! initialization by implied-DO list
DATA ((B(i), I = 1, 4) = [11.0, 12.0, 13.0, 14.0])
```

The following example shows DATA statements containing structure components:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
TYPE(EMPLOYEE) MAN_NAME, CON_NAME
DATA MAN_NAME / EMPLOYEE(417, 'Henry Adams') /
DATA CON_NAME%ID, CON_NAME%NAME /891, "David James"/
```

In the following example, the first DATA statement assigns zero to all 10 elements of array A, and four asterisks followed by two blanks to the character variable STARS:

```
 INTEGER A(10), B(10)
 CHARACTER BELL, TAB, LF, FF, STARS*6
 DATA A,STARS /10*0,'****'/
 DATA BELL,TAB,LF,FF /7,9,10,12/
 DATA (B(I), I=1,10,2) /5*1/
```

In this case, the second DATA statement assigns ASCII control character codes to the character variables BELL, TAB, LF, and FF. The last DATA statement uses an implied-DO list to assign the value 1 to the odd-numbered elements in the array B.

The following shows another example:

```
    INTEGER n, order, alpha, list(100)
    REAL coef(4), eps(2),
    pi(5), x(5,5)
    CHARACTER*12 help
    COMPLEX*8 cstuff
    DATA  n /0/, order /3/
    DATA  alpha /'A'/
    DATA  coef /1.0, 2*3.0, 1.0/, eps(1) /.00001/
    DATA  cstuff /(-1.0, -1.0)/
!    The following example initializes diagonal and below in
!    a 5x5 matrix:
    DATA  ((x(j,i), i=1,j), j=1,5) / 15*1.0 /
    DATA  pi / 5*3.14159 /
    DATA  list / 100*0 /
    DATA  help(1:4), help(5:8), help(9:12) /3*'HELP'/
```

Consider the following:

```
CHARACTER (LEN = 10) NAME
INTEGER, DIMENSION (0:9) :: MILES
REAL, DIMENSION (100, 100) :: SKEW
TYPE (MEMBER) MYNAME, YOURS
DATA NAME / 'JOHN DOE' /, miles / 10*0 /
DATA ((SKEW (k, j), j = 1, k), k = 1, 100) / 5050*0.0 /
DATA ((SKEW (k, j), j = k + 1, 100), k = 1, 99) / 4950*1.0 /
DATA MYNAME / MEMBER (21, 'JOHN SMITH') /
DATA YOURS % age, YOURS % name / 35, 'FRED BROWN' /
```

In this example, the character variable NAME is initialized with the value JOHN DOE with two trailing blanks to fill out the declared length of the variable. The ten elements of MILES are initialized to zero. The two-dimensional array SKEW is initialized so that its lower triangle is zero and its upper triangle is one. The structures MYNAME and YOURS are declared using the derived type MEMBER. The derived-type variable MYNAME is initialized by a structure constructor. The derived-type variable YOURS is initialized by supplying a separate value for each component.

The first DATA statement in the previous example could also be written as:

```
DATA name / 'JOHN DOE' /
DATA miles / 10*0 /
```

A pointer can be initialized as disassociated by using a DATA statement. For example:

```
INTEGER, POINTER :: P
DATA P/NULL( )/
END
```

The implied-DO limits can be any constant expressions in a DATA statement. For example:

```
DATA (A(I),I=LBOUND(A),UBOUND(A)) /10*4.0/
```

DATE Intrinsic Procedure

Intrinsic Subroutine (Generic): *Returns the current date as set within the system. DATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL DATE (buf)
```

buf	(Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least nine bytes of storage.

The date is returned as a 9-byte ASCII character string taking the form dd-mmm-yy, where:

dd	is the 2-digit date
mmm	is the 3-letter month
yy	is the last two digits of the year

If *buf* is of numeric type and smaller than 9 bytes, data corruption can occur.

If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 9 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

> **Caution**
> The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```
CHARACTER*1 DAY(9)
…
CALL DATE (DAY)
```

The length of the first array element in CHARACTER array DAY is passed to the DATE subroutine. The subroutine then truncates the date to fit into the 1-character element, producing an incorrect result.

DATE portability routine

DATE Portability Routine
Portability Function or Subroutine: *Returns the current system date. DATE can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.*

Module
USE IFPORT

Syntax
Function Syntax:

```
result = DATE( )
```

Subroutine Syntax:

```
CALL DATE (dstring)
```

dstring	(Output) CHARACTER. Is a variable or array containing at least nine bytes of storage.

DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where mm, dd, and yy are two-digit representations of the month, day, and year, respectively.

DATE in its subroutine form returns *dstring* in the form dd-mmm-yy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yy are the last two digits of the current year.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```
USE IFPORT
!If today's date is March 02, 2000, the following
!code prints "02-Mar-00"
CHARACTER(9) TODAY
CALL DATE(TODAY)
PRINT *, TODAY
!The next line prints "03/02/00"
PRINT *, DATE( )
```

See Also
DATE_AND_TIME

DATE intrinsic procedure

DATE4

Portability Subroutine: *Returns the current system date.*

Module

USE IFPORT

Syntax

```
CALL DATE4 (datestr)
```

datestr (Output) CHARACTER. Is a variable or array containing at least eleven bytes of storage.

This subroutine returns *datestr* in the form dd-mmm-yyyy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yyyy are the four digits of the current year.

DATE_AND_TIME

Intrinsic Subroutine (Generic): *Returns character and binary data on the real-time clock and date. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL DATE_AND_TIME ([date,time,zone,values])
```

date (Output; optional) Must be scalar and of type default character; its length must be at least 8 to contain the complete value. Its leftmost 8 characters are set to a value of the form CCYYMMDD, where:

CC	Is the century
YY	Is the year within the century
MM	Is the month within the year
DD	Is the day within the month

time (Output; optional) Must be scalar and of type default character; its length must be at least 10 to contain the complete value. Its leftmost 10 characters are set to a value of the form hhmmss.sss, where:

hh	Is the hour of the day
mm	Is the minutes of the hour
ss.sss	Is the seconds and milliseconds of the minute

zone (Output; optional) Must be scalar and of type default character; its length must be at least 5 to contain the complete value. Its leftmost 5 characters are set to a value of the form +hhmm or -hhmm, where *hh* and *mm* are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively.

UTC is also known as Greenwich Mean Time.

values (Output; optional) Must be of type integer. One-dimensional array with size of at least 8. The values returned in *values* are as follows:

values(1)	Is the 4-digit year
values(2)	Is the month of the year
values(3)	Is the day of the month
values(4)	Is the time difference with respect to Coordinated Universal Time (UTC) in minutes
values(5)	Is the hour of the day (range 0 to 23) - local time
values(6)	Is the minutes of the hour (range 0 to 59) - local time
values(7)	Is the seconds of the minute (range 0 to 59) - local time
values(8)	Is the milliseconds of the second (range 0 to 999) - local time

Example

Consider the following example executed on 2000 March 28 at 11:04:14.5:

```
INTEGER DATE_TIME (8)
CHARACTER (LEN = 12) REAL_CLOCK (3)
CALL DATE_AND_TIME (REAL_CLOCK (1), REAL_CLOCK (2), &
                    REAL_CLOCK (3), DATE_TIME)
```

This assigns the value "20000328" to REAL_CLOCK (1), the value "110414.500" to REAL_CLOCK (2), and the value "-0500" to REAL_CLOCK (3). The following values are assigned to DATE_TIME: 2000, 3, 28, -300, 11, 4, 14, and 500.

The following shows another example:

```
CHARACTER(10) t
CHARACTER(5) z
CALL DATE_AND_TIME(TIME = t, ZONE = z)
```

CLOCK

DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN

Portability Functions: *Compute the double-precision values of Bessel functions of the first and second kinds.*

Module

USE IFPORT

Syntax

```
result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)
```

value	(Input) REAL(8). Independent variable for a Bessel function.
n	(Input) INTEGER(4). Specifies the order of the selected Bessel function computation.
posvalue	(Input) REAL(8). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results

DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and *n*, respectively, with the independent variable *value*.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and *n*, respectively, with the independent variable *posvalue*.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions*(Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

Example

```
    USE IFPORT
    real(8) besnum, besout
10  read *, besnum
    besout = dbesj0(besnum)
    print *, 'result is ',besout
    goto 10
    end
```

See Also

BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

DBLE

Elemental Intrinsic Function (Generic): *Converts a number to double-precision real type.*

Syntax

```
result = DBLE (a)
```

a (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.

Results

The result type is double precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If *a* is of type double precision, the result is the value of the *a* with no conversion (DBLE(*a*) = *a*).

If *a* is of type integer or real, the result has as much precision of the significant part of *a* as a double precision value can contain.

If *a* is of type complex, the result has as much precision of the significant part of the real part of *a* as a double precision value can contain.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1)	REAL(8)
	INTEGER(2)	REAL(8)
	INTEGER(4)	REAL(8)
	INTEGER(8)	REAL(8)
DBLE[2]	REAL(4)	REAL(8)
	REAL(8)	REAL(8)
DBLEQ	REAL(16)	REAL(8)
	COMPLEX(4)	REAL(8)
	COMPLEX(8)	REAL(8)
	COMPLEX(16)	REAL(8)

[1]These specific functions cannot be passed as actual arguments.

[2] The setting of compiler options specifying double size can affect DBLE.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

NOTE
The result values of DBLE are defined by references to the intrinsic function REAL with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to DBLE is the same as for the intrinsic function REAL.

Example

DBLE (4) has the value 4.0.

DBLE ((3.4, 2.0)) has the value 3.4.

DCLOCK

Portability Function: *Returns the elapsed time in seconds since the start of the current process.*

Module

USE IFPORT

Syntax

```
result = DCLOCK( )
```

Results

The result type is REAL(8). This routine provides accurate timing to the nearest millisecond (Windows*) or to the nearest microsecond (Linux*), taking into account the frequency of the processor where the current process is running.

Note that the first call to DCLOCK performs calibration.

Example

```
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME
START_TIME = DCLOCK()
CALL FOO()
STOP_TIME = DCLOCK()
PRINT *, 'foo took:', STOP_TIME - START_TIME, 'seconds.'
```

See Also

DATE_AND_TIME
CPU_TIME

DCMPLX

Elemental Intrinsic Function (Specific): *Converts the argument to double complex type. This function cannot be passed as an actual argument.*

Syntax

```
result = DCMPLX (x[,y])
```

x (Input) Must be of type integer, real, or complex.

y	(Input; optional) Must be of type integer or real. It must not be present if *x* is of type complex.

Results

The result type is double complex (COMPLEX(8) or COMPLEX*16).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If *y* is not specified and *x* is complex, the result value is CMPLX(REAL(*x*), AIMAG(*x*)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

DCMPLX(*x*, *y*) has the complex value whose real part is REAL(*x*, KIND=8) and whose imaginary part is REAL(*y*, KIND=8).

Example

DCMPLX (-3) has the value (-3.0, 0.0).

DCMPLX (4.1, 2.3) has the value (4.1, 2.3).

DEALLOCATE

Statement: *Frees the storage allocated for allocatable variables and nonprocedure pointer targets (and causes the pointers to become disassociated).*

Syntax

`DEALLOCATE (`*object*`[,`*object*`]...[, `*dealloc-opt*`])`

object	Is a structure component or the name of a variable, and must be a pointer or allocatable variable.
dealloc-opt	(Output) Is one of the following:
`STAT=`*stat-var*	*stat-var* is a scalar integer variable in which the status of the deallocation is stored.
`ERRMSG=`*err-var*	*err-var* is a scalar default character value in which an error condition is stored if such a condition occurs.

Description

If a STAT= variable or ERRMSG= variable is specified, it must not be deallocated in the DEALLOCATE statement in which it appears. If the deallocation is successful, the STAT= variable is set to zero and the ERRMSG= variable is unchanged. If the deallocation is not successful, an error condition occurs, the STAT=

variable is set to a positive integer value (representing the runtime error), and the ERRMSG= variable is defined with a descriptive message about the error condition. If no STAT= variable is specified and an error condition occurs, error termination is initiated.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images has initiated termination of execution, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. Otherwise, if an allocatable object is a coarray and one or more images of the current team has failed, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT= variable becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has failed, each allocatable object is successfully allocated or deallocated on the active images of the current team. If any other error occurs, the allocation status of each allocatable object is processor dependent:

- Successfully allocated allocatable objects have the allocation status of allocated, or associated if the allocate object is has the POINTER attribute.
- Successfully deallocated allocatable objects have the allocation status of deallocated, or disassociated if the allocatable object has the POINTER attribute.
- An allocatable object that was not successfully allocated or deallocated has its previous allocation status, or its previous association status if it has the POINTER attribute.

It is recommended that all explicitly allocated storage be explicitly deallocated when it is no longer needed.

To disassociate a pointer that was not associated with the ALLOCATE statement, use the NULLIFY statement.

For a list of runtime errors, see Error Handling.

Example

The following example shows deallocation of an allocatable array:

```
INTEGER ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)
...
ALLOCATE (A(10), B(-2:8,1:5))
...
DEALLOCATE(A, B, STAT = ALLOC_ERR)
```

The following shows another example:

```
INTEGER, ALLOCATABLE :: dataset(:,:,:)
INTEGER reactor, level, points, error
DATA reactor, level, points / 10, 50, 10 /
ALLOCATE (dataset(1:reactor,1:level,1:points), STAT = error)
DEALLOCATE (dataset, STAT = error)
```

DECLARE and NODECLARE

General Compiler Directives: *DECLARE generates warnings for variables that have been used but have not been declared (like the IMPLICIT NONE statement). NODECLARE (the default) disables these warnings.*

Syntax

```
!DIR$ DECLARE
!DIR$ NODECLARE
```

The DECLARE directive is primarily a debugging tool that locates variables that have not been properly initialized, or that have been defined but never used.

Equivalent Compiler Options

DECLARE MAPPER

OpenMP* Fortran Compiler Directive: *Declares a user-defined mapper for a specified type. It also lets you optionally declare a map-identifier that can be used in a MAP clause in other directives or in a motion-clause of a TARGET UPDATE directive. This feature is only available for ifx.*

Syntax

```
!$OMP DECLARE MAPPER ([mapper-identifier:] type::var) [clause [[,] clause]...]
```

mapper-identifier

Is a Fortran identifier, or the literal string DEFAULT. If no *mapper-identifier* is specified, it is as if DEFAULT was specified.

A DECLARE MAPPER directive specifying a *mapper-identifier* for a given type is not permitted in a scope where another DECLARE MAPPER directive specifying the same *mapper-identifier* for the same type is accessible.

type

Is an accessible type name within the scope where the directive appears. It cannot be an intrinsic or an abstract type.

type cannot be directly or indirectly mapped as part of the mapper through another type, except through the appearance of *var* as a list item in a MAP clause.

If *type* identifies a derived type, it can be any accessible derived type name. In the Description below, DT refers to a derived type identifier.

var

Is a Fortran identifier. It can be used in all MAP clauses of the DECLARE MAPPER directive. No subobject of *var* is default mapped; all parts of *var* must be explicitly mapped.

var, or at least one element or component of *var*, must appear in a MAP clause.

clause

Is MAP ([[map-type-modifier[,]] map-type :] list).

map-type-modifier is ALWAYS, CLOSE, OR PRESENT.

map-type is ALLOC, TO, FROM or TOFROM.

Each *map-type* can appear only once in a MAP clause. If *map-type* is not specified, it is as if TOFROM appeared as the *map-type*.

list items are limited to references of *var*, or other objects that are accessible in the scope or are previously declared in the scope where the DECLARE MAPPER directive appears. A list item can be an array section.

The DECLARE MAPPER directive is a declarative directive that appears in the specification part of a program. It is a pure directive, so it can appear in a Fortran PURE procedure. *type* and *mapper-identifier*, if present, uniquely identify the mapper.

If a DECLARE MAPPER directive is not specified for a type DT, a predefined mapper exists for type DT as if the type DT had appeared in the directive as follows:

```
!$OMP DECLARE MAPPER (DT :: var) MAP (TOFROM: var)
```

A DECLARE MAPPER directive that uses the *mapper-identifier* DEFAULT for any type DT overrides this predefined mapper for the type DT, and the user-declared mapper becomes the default mapper for all variables of type DT.

If a MAP clause in another directive maps a list item of a type specified in an accessible DECLARE MAPPER directive, or if a motion clause of a TARGET UPDATE invokes a user-defined mapper and updates a list item of type specified by that mapper, the effect is as if the MAP or motion clause is replaced by a set of MAP or motion clauses derived from the MAP clauses specified on the DECLARE MAPPER directive.

A derived type list-item can have more than one map type: one from DECLARE MAPPER, and one from a MAP clause in a TARGET construct.

The following table shows the final map type a mapper applies for a MAP clause that maps a list item of the given type:

- The rows are the *map-type* specified by the mapper.
- The columns are the specified *map-type* of the MAP clause invoking the mapper.
- The parenthesized values in the table represent the final map type for a TARGET EXIT DATA construct that invokes a mapper.

  In this case, if the mapper specifies *map-type* ALLOC or TO, and the TARGET EXIT DATA MAP clause that invokes the mapper has *map-type* FROM, the resulting *map-type* is RELEASE.

Map result type of map type combinations

	ALLOC	TO	FROM	TOFROM	RELEASE	DELETE
ALLOC	ALLOC	ALLOC	ALLOC (RELEASE)	ALLOC	RELEASE	DELETE
TO	ALLOC	TO	ALLOC (RELEASE)	TO	RELEASE	DELETE
FROM	ALLOC	ALLOC	FROM	FROM	RELEASE	DELETE
TOFROM	ALLOC	TO	FROM	TOFROM	RELEASE	DELETE

If a set of DECLARE MAPPER directives result in a cyclic definition of mappers, it causes unspecified behavior.

Example

The following example contains a DECLARE MAPPER directive that maps derived types of type `my_type`. The variable `var` has the type `my_type` and is used in the MAP clause to reference the derived type and its components.

The MAP clause in the DECLARE MAPPER directive specifies that all components of `my_type` are mapped, as well as the dynamic storage in the array section var%values(1:NUM_ELEMENTS). No *map-type* is specified, so the map type TOFROM is assumed.

Variables used in TARGET regions that are of type `my_type` will be implicitly mapped as prescribed in the DECLARE MAPPER directive's MAP clause.

```
 program main
 integer,parameter      :: nvals = 250
 type my_type
   integer              :: num_vals
   integer, allocatable :: values(:)
 end type
 type (my_type)          :: t
 !$omp declare mapper (my_type :: var) map (var, var%values (1:var%num_vals))

 t%num_vals = nvals
 allocate (t%values(t%num_vals))
 !$omp target
 call initial_vals (t)
 !$omp end target
 ...
 contains
   subroutine initial_vals (v)
   type (my_type) :: v
   v%values = 0
   end subroutine initial_vals
  end program
```

The following example maps the type `my_type` as seen in the previous example.

Type `my_type` is nested within another derived type, `my_type2`. `my_type2` is mapped by a second DECLARE MAPPER directive.

The array component `unmapped` is not mapped and is available on the host only. The component `temp` is allocated on the target and used as temporary storage on the target device. The component `arr` is mapped with the default map type TOFROM. The two mappers are combined when mapping variables of type `my_type2`.

The second DECLARE MAPPER directive uses a *mapper-identifier*, and maps the variable `x` and the array `y` as well as the type `my_type2`.

```
program main
 integer,parameter      :: nvals = 250
 type my_type
   integer              :: num_vals
   integer, allocatable :: values(:)
 end type
 !$omp declare mapper (my_type :: var) map (var, var%values (1:var%num_vals))

 type my_type2
   type (my_type)        :: my_type_var
   type (my_type)        :: temp
   real,dimension(nvals) :: unmapped
```

```
 real,dimension(nvals) :: arr
end type
type (my_type2)        :: t
real                   :: x, y(num_vals)
!$omp declare mapper (my_mapper : my_type2 :: v) map (v%arr, x, y(:)) &
!$omp&                map (alloc : v%temp)

!$omp target map (mapper(my_mapper), tofrom : t)
  call calculate(t, x, y)
!$omp end target
...
 end program
```

TARGET UPDATE

DECLARE REDUCTION

OpenMP* Fortran Compiler Directive: *Declares user-defined reductions which are identified by a reduction-identifier that can be used in a reduction clause of other directives.*

Syntax

`!$OMP DECLARE REDUCTION (`*reduction-identifier* `:` *type-list* `:` *combiner*`) [`*initializer-clause*`]`

reduction-identifier

Is a Fortran identifier, or a defined or extended operator.

type-list

Is a comma-separated list of one or more type identifiers. These may be intrinsic types or accessible derived types. You cannot specify polymorphic and parameterized derived types, and coarrays.

type-list cannot contain a type which has previously been specified in a DECLARE REDUCTION directive with the same *reduction-identifier* if the *reduction-identifier*/type pair is accessible by use or host association.

If more than one type is specified, it is as if there is a separate DECLARE REDUCTION directive for each type.

combiner

Is an assignment statement, or a subroutine name followed by an argument list. It indicates how partial results are combined into a single value.

There are two special identifiers that are allowed in the *combiner*:

- `omp_out`

  This identifier refers to the storage that holds the resulting combined value following execution of the combiner.
- `omp_in`

The above identifiers refer to variables that are the type of the reduction variables specified in *type-list* for the *reduction-identifier*. They denote values to be combined by executing the *combiner*.

No other identifiers are permitted in the *combiner*. Any number of literal or named constants can appear in the *combiner*.

If *combiner* is a subroutine name followed by an argument list, it is evaluated by calling the subroutine with the specified argument list. If *combiner* is an assignment statement, *combiner* is evaluated by executing the assignment statement.

The number of times the *combiner* is executed, and the order of these executions, is unspecified.

initializer-clause

Is `initializer` (*initializer-expression*).

At most one *initializer-clause* can be specified.

Only the identifiers `omp_priv` and `omp_orig` are allowed in the *initializer-clause*. `omp_orig` refers to the storage of the original reduction variable that appears in the list in the REDUCTION clause that specifies *reduction-identifier*. If `omp_orig` is modified in the *initializer-clause*, the behavior is unspecified.

No other identifiers are allowed in *initializer-clause*. Any number of literal or named constants are permitted.

initializer-expression

Is one of the following identifiers:

- `omp_priv` = *expression*

  This identifier refers to the storage to be initialized.
- subroutine-name (*argument-list*)

If *initializer-expression* is a subroutine name and an argument list, the `initializer` is evaluated by executing a call to the subroutine with the specified argument list. If `initializer` is an assignment statement, it is evaluated by executing the assignment.

If *initializer-expression* is a subroutine name and an argument list, one of the arguments must be `omp_priv`, and it must be associated with an INTENT(OUT) dummy argument of the subroutine.

The number of times *initializer-expression* is evaluated and the order of the evaluations is unspecified.

The DECLARE REDUCTION directive is a specification directive. It can appear in a specification part of a subroutine, function, main program, module, or block construct. It is a pure directive, so it can appear in a Fortran PURE procedure.

User-defined (custom) reductions can be defined using the DECLARE REDUCTION directive. The reduction is identified by the *reduction-identifier* and the associated type from *type-list*. The *reduction-identifier* can be used in a REDUCTION clause in another OpenMP* directive anywhere it is accessible by use or host association.

A DECLARE REDUCTION directive cannot redefine a predefined *reduction-identifier* (see the table of implicitly defined reduction identifiers in the REDUCTION clause section).

If a type in *type-list* has deferred or assumed-length type parameters, the *reduction-identifier* can be used in a REDUCTION clause with a variable of the same type and kind type parameter as type, regardless of the length parameter with which the variable is declared. The length parameter of a character type must be a constant, colon, or asterisk. An accessible *reduction-identifier* defined with a deferred or assumed-length character type cannot appear in another DECLARE REDUCTION directive with a *type-list* item of type character with the same kind type parameter.

The accessibility of a *reduction-identifier* is determined by the same rules as for other Fortran entities; it can be declared PUBLIC or PRIVATE, be made accessible or blocked by a USE or IMPORT statement, and it can be renamed. If the *reduction-identifier* is the same as a generic name that is also the name of a derived type, the accessibility of the *reduction-identifier* is the same as that of the generic name.

If a subroutine or function used in *initializer-expression* or *combiner* is not an intrinsic procedure, it must have an accessible interface. Defined operators and defined assignments used in `initializer` or *combiner* must have accessible interfaces. All subroutines, functions, defined operators and defined assignments used in `initializer` or *combiner* must have accessible interfaces in the subprogram in which the corresponding REDUCTION clause appears. Procedures referenced in *combiner* and `initializer` cannot be alternate return subprograms.

The initial value of a user-defined reduction is not known before it is specified. The *initializer-clause* can be used to specify an initial value for the reduction variable. The *initializer-clause* will be executed to establish initial values for the private copies of reduction list items indicated in a REDUCTION clause that specifies the *reduction-identifier*.

If `initializer` is not specified, private reduction variables are initialized as follows:

- If the reduction variable is type COMPLEX, REAL, or INTEGER, the default initializer is the value zero.
- If the reduction variable specified in list of the REDUCTION clause is LOGICAL, the default initializer is the value .FALSE..
- If the reduction variable is of a default initialized derived type, the default initializer value is used.
- Otherwise, the initial value is unspecified.

If `initializer` is used in a target region, then a DECLARE TARGET construct (Linux* only) must be specified for any procedures that are executed during the execution of *combiner* or `initializer`.

If the execution of *combiner* or `initializer` results in the execution of an OpenMP* construct or an OpenMP* API call, the behavior is undefined. If the variable `omp_orig` is defined during execution of `initializer`, the behavior is unspecified.

Example

Consider that a DECLARE REDUCTION directive is used to declare a sum reduction for an integer component of a type `my_type` that is identified by the *reduction-identifier* '+'. It is then used in a REDUCTION clause of a parallel region to produce the sum of the thread numbers (numbered 1 thru 4) of the region:

```
module types
  type my_type
    integer :: component
  end type
  interface operator(+)
    module procedure :: my_add
  end interface
!$omp declare reduction (+ : my_type : omp_out = omp_out + omp_in) initializer (omp_priv =
my_type (0))

  contains
    function my_add (a1, a2)
      type(my_type),intent(in) :: a1, a2
      type(my_type)            :: my_add
      my_add%component = a1%component + a2%component
      return
    end function my_add
end module types

program main
  use types
  use omp_lib
```

```
  type(my_type) :: my_var

! Initialize the reduction variable before entering the OpenMP region
  my_var%component = 0

!$omp parallel reduction (+ : my_var) num_threads(4)
  my_var%component = omp_get_thread_num() + 1
!$omp end parallel

  print *, "sum of thread numbers is ", my_var%component
end program
```

The output of the program follows:

```
sum of thread numbers is 10
```

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
DECLARE TARGET
REDUCTION clause

DECLARE SIMD

OpenMP* Fortran Compiler Directive: *Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.*

Syntax

`!$OMP DECLARE SIMD(`*routine-name*`) [`*clause*`[[,] `*clause*`]... ]`

routine-name

Is the name of a routine (a function or subroutine). It cannot be a generic name; it must be a specific name. It also cannot be a procedure pointer or an entry name.

clause

Is an optional vectorization clause. It can be one or more of the following:

- ALIGNED (list [:n])
- `INBRANCH | NOTINBRANCH`

  The INBRANCH clause specifies that the routine must always be called from inside a conditional statement of a SIMD loop.

  The NOTINBRANCH clause specifies that the routine must never be called from inside a conditional statement of a SIMD loop.

  If neither clause is specified, then the routine may or may not be called from inside a conditional statement of a SIMD loop.

  You can only specify INBRANCH or NOTINBRANCH; you cannot specify both.
- LINEAR (linear-list [: linear-modifier [, linear-modifier]])
- PROCESSOR (cpuid) (an Intel® language extension)
- `SIMDLEN(`*n*`)`

Specifies the number of concurrent arguments (*n*) for the SIMD version of *routine-name*. The *n* must be a constant positive integer expression.

If SIMDLEN is not specified, the number of concurrent arguments for the *routine-name* is implementation defined.

Only one SIMDLEN clause can appear in a DECLARE SIMD directive.

- `UNIFORM`(*list*)

  Tells the compiler that the values of the specified arguments have an invariant value for all concurrent invocations of the routine in the execution of a single SIMD loop.

  The *list* is one or more scalar variables that are dummy arguments in the specified routine.

  Multiple UNIFORM clauses are merged as a union.

The DECLARE SIMD construct enables the creation of SIMD versions of the specified subroutine or function. You can use multiple DECLARE SIMD constructs in a single procedure to produce more than one SIMD version of a procedure. These versions can be used to process multiple arguments from a single invocation from a SIMD loop concurrently.

DECLARE SIMD is a pure directive, so it can appear in a Fortran PURE procedure.

When *routine-name* is executed, it cannot have any side-effects that would change its execution for concurrent iterations of a SIMD chunk. When the routine is called from a SIMD loop, it cannot cause the execution of any OpenMP* Fortran construct.

If a DECLARE SIMD directive is specified for a routine name with explicit interface and for the definition of the routine, they must match. Otherwise, the result is unspecified.

You cannot use procedure pointers to access routines created by the DECLARE SIMD directive.

You can only specify a particular variable in at most one instance of a UNIFORM or LINEAR clause.

OpenMP Fortran Compiler Directives

Syntax Rules for Compiler Directives

DECLARE TARGET

OpenMP* Fortran Compiler Directive: *Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This feature is only available for ifx.*

Syntax

```
!$OMP DECLARE TARGET [(extended-list)]
```

-or-

```
!$OMP DECLARE TARGET [clause[[,]clause]...]
```

extended-list

Is a list of one or more variables or array sections that are neither coindexed nor substrings, a common block name enclosed in slashes, or a procedure name. If you specify more than one *extended-list* item, they must be separated by commas. A common block name must appear between slashes (/ /); you cannot specify a blank common block.

The specified *extended-list* items can be used inside a target region that executes on the device.

Any list items that have appeared in a GROUPPRIVATE directive are treated as if they appear in an implicit LOCAL clause in the DECLARE TARGET directive; other list items with the SAVE attribute are treated as if they appear in an implicit ENTER clause on the DECLARE TARGET directive.

If the *extended-list* item is a procedure name, it must not be a generic name or entry name. A device-specific version of the routine is created that can be called from a target region.

If the *extended-list* item is a variable:

- It is mapped to a corresponding variable in the device data environment. If the variable is initialized, the corresponding variable in the device data environment is initialized with the same value.
- It can only appear in the scope in which it is declared.
- It must be declared in the Fortran scope of a module, or it must have the SAVE attribute (explicitly or implicitly).

You cannot specify the following variables in the DECLARE TARGET directive:

- A THREADPRIVATE variable
- A variable that is part of another variable (for example, an element in an array or a field of a structure)
- A variable that is an element of a common block
- A variable that appears in an EQUIVALENCE statement

If the *extended-list* item is a common block:

- It must be declared to be a common block in the same scoping unit in which the DECLARE TARGET directive appears.
- If the DECLARE TARGET directive specifying the common block name appears in one program unit, a DECLARE TARGET directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. The directive must appear after the last relevant COMMON statement in the program unit.

clause

Is one of the following:

- DEVICE_TYPE (device)
- ENTER (*extended-list*)

  ENTER replaces TO, which has been deprecated.

  extended-list is a comma-separated collection of one or more *list* items or procedures.

  If a *list* item is a procedure, then a device-specific version of the procedure is created that can be called from a target region.

  If a *list* item is a variable then the original variable is mapped to a corresponding variable in the device data environment as if it had appeared in a MAP clause with the *map-type* TO on the implicit TARGET DATA construct for each device.

The *list* item is never removed from those device data environments.

- INDIRECT [(*invoked-by-ptr-ref*)]

  invoked-by-ptr-ref is a constant scalar logical expression evaluated at compile time.

  If it evaluates to .TRUE., or if it is omitted, procedures specified in an ENTER clause can be called by an *indirect device invocation*. If it evaluates to .FALSE., procedures specified in an ENTER clause cannot be called by an *indirect device invocation*. See the Glossary, section I, for the definition of *indirect device invocation*.

  If the INDIRECT clause does not appear in the directive, procedures specified in an ENTER clause cannot be called by an *indirect device invocation*.
- LINK (*list*)

  Maps the *list* items for specific device executions, supporting functions called in a TARGET region that refer to the list items. *list* items are mapped as if they had appeared in a MAP clause with a *map-type* of TOFROM.

  The *list* is a comma-separated list of one or more non-coindexed variables, arrays, array sections, named constants, associate names, or common block names enclosed in slashes (//).

  A LINK list item cannot be a variable for which NOHOST has been specified.
- LOCAL (*variable-list*)

  Specifies that references to list items are references to device local copies of the list items stored in memory local to the device. The *variable-list* items can be variables or array sections.
- TO (*extended-list*) - deprecated (see ENTER clause above)

  The *extended-list* is a comma-separated collection of one or more *list* items or procedures.

  If a *list* item is a procedure, then a device-specific version of the procedure is created that can be called from a target region.

  If a *list* item is a variable then the original variable is mapped to a corresponding variable in the device data environment as if it had appeared in a MAP clause with the *map-type* TO on the implicit TARGET DATA construct for each device.

  The *list* item is never removed from those device data environments.

If you specify *list*, this directive can only appear in a specification part of a subroutine, function, program, or module. It is a pure directive, so it can appear in a Fortran PURE procedure.

If you do not specify *list*, the directive must appear in the specification part of the enclosing subroutine, function, or interface block.

If no *clause* and no *extended-list* appear, the behavior is as if an implicit ENTER clause appears with one list item that is the name of the enclosing subroutine or function.

If *extended-list* appears, no *clause*s can appear in the directive. If a *clause* appears, the directive must contain at least one ENTER, LINK, LOCAL, or TO clause. An object that has been declared in a GROUPPRIVATE directive cannot be a list item in a ENTER or LINK clause.

The DEVICE_TYPE clause indicates if versions of the procedure should be compiled for the host, device, or both. Specifying HOST results in only a host version being compiled, specifying NOHOST compiles a version for only the device, and specifying ANY indicates a version for both host and device should be compiled.

If no DEVICE_TYPE clause is present, it is as if DEVICE_TYPE (ANY) appears. Internal procedures contained in a procedure that has a DEVICE_TYPE clause in a DECLARE TARGET directive cannot contain DECLARE TARGET directives themselves; the enclosing DEVICE_TYPE clause implicitly applies to the internal procedures.

At most one DEVICE_TYPE clause can appear. If an INDIRECT clause appears and *invoked-by-ptr-ref* evaluates to .TRUE., DEVICE_TYPE must be ANY.

If a DECLARE TARGET directive is specified in an interface block for a procedure, it must match a DECLARE TARGET directive in the definition of the procedure, including the DEVICE_TYPE clause if it appears.

If a procedure is declared in a procedure declaration statement, any DECLARE TARGET directive containing the procedure name must appear in the same specification part.

A DECLARE TARGET directive with no clauses, or one that has a DEVICE_TYPE clause must appear in the specification part of a subroutine or function subprogram, or in an interface body.

A *list* item cannot appear as both an *extended-list* item in an ENTER clause in one DECLARE TARGET directive, and as a list item in a LINK clause in another DECLARE TARGET directive. An *extended-list* item in an ENTER clause must not have an initializer that references a list item in a LINK clause on a DECLARE TARGET directive.

The following additional rules apply to variables and common blocks:

- The DECLARE TARGET directive must appear in the declaration section of a scoping unit in which the common block or variable is declared.
- If a variable or common block is declared with the BIND attribute, the corresponding C entities must also be specified in a DECLARE TARGET directive in the C program.

Variables with static storage and procedures used in an OMP TARGET region are implicitly treated as OMP DECLARE TARGET:

```
MODULE VARS
  INTEGER X
END MODULE

REAL FUNCTION FOO()
END FUNCTION

!$OMP TARGET
  X = FOO()       ! X and FOO are implicitly DECLARE TARGET
!$OMP END TARGET
```

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DECLARE VARIANT

OpenMP* Fortran Compiler Directive: *Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.*

Syntax

```
!$OMP DECLARE VARIANT ([base-proc-name:]variant-proc-name) clause[[[,] clause]... ]
```

base-proc-name

Is the name of a base procedure. It is the name that appears in a procedure reference and is replaced by the variant name if the procedure reference appears in the OpenMP* context specified by the MATCH clause. *base-proc-name* must have an accessible explicit interface.

variant-proc-name

Is the name of the variant procedure that is to be called instead of the base procedure if the base procedure is called from an OpenMP* context that matches the context specified by the MATCH clause.

clause

Is one or more of the following:

- ADJUST_ARGS (*adjust-op* : *argument-list*)

  Causes the *adjust-op* operation to be performed to each argument specified in *argument-list* before calling the variant procedure.

  adjust-op is either `need_device_ptr` or `nothing`.

  If `need_device_ptr` is specified, it causes the listed arguments to be converted to corresponding device pointers of the default device. An argument in the *argument-list* following `need_device_ptr` must be of type C_PTR.

  If `nothing` is specified, the arguments listed are passed without modification.

  Multiple ADJUST_ARG clauses can appear for a DECLARE VARIANT directive.
- APPEND_ARGS (*append-op* [[, *append-op*] …]

  Causes additional arguments to be passed to the call at the end of the argument list of the base procedure.

  append-op is:

  INTEROP (*modifier-list*)

  where *modifier-list* is a valid *modifier-list* accepted in an INIT clause of the INTEROP directive.

  Only one APPEND_ARGS clause can appear in a DECLARE VARIANT directive.
- MATCH (*context-selector-specification-list*)

  Specifies OpenMP* context selectors that determine if a variant function is to be used as a base function replacement in the specified context. Any variable referenced in an expression of a context selector must be accessible at the call site to the base function.

An APPEND_ARGS clause or ADJUST_ARGS clause is not permitted unless a MATCH clause also appears that specifies CONSTRUCT={DISPATCH} as a selector.

The DECLARE VARIANT directive is a declarative directive and must appear in the specification part of a subroutine or function, or in an interface in an interface block. It is a pure directive, so it can appear in a Fortran PURE procedure. It identifies the name of a variant procedure that is to be called instead of the base procedure when the call appears in a context that matches the *context-selector-specification* in the MATCH clause.

If *base-proc-name* is not specified, the name of the procedure containing the directive is the *base-proc-name*. *base-proc-name* must not be a dummy procedure name, a statement function name, a generic name, a procedure pointer, or an alternate entry name.

If a DECLARE VARIANT directive appears in an interface body for a procedure, it must match a DECLARE VARIANT directive in the definition of that procedure. If a DECLARE VARIANT directive appears for a procedure with an explicit interface, and the definition of that procedure also contains a DECLARE VARIANT directive for that procedure, the two directives must match.

Multiple DECLARE VARIANT directives can associate different *variant-proc-name*s with the same *base-proc-name*. If more than one DECLARE VARIANT associates the same *variant-proc-name* with the same *base-proc-name*, then the *context-selector-specification* must be the same for all such directives.

A variant procedure must have the same interface characteristics as the base procedure.

When the ADJUST_ARGS clause is specified, an argument with the is-device-ptr property in its interoperability requirement set will be passed as is. Otherwise, the argument will be converted in the same way that a USE_DEVICE_PTR clause on a TARGET DATA construct converts a pointer list item into a device pointer.

When the APPEND_ARGS clause appears, the following occurs:

- For each *modifier* specified, an additional argument of type omp_interop_kind from the interoperability requirement set of the encountering task is added to the end of the argument list of the base procedure.

  The ordering of the appended arguments is the same as the order of the *modifier*s that are specified in *modifier-list* in parentheses following the INTEROP keyword in the APPEND_ARGS clause.
- Each argument is constructed as if an INTEROP construct specifying an INIT clause with the corresponding *modifier* was present.
- If the interoperability requirement set contains properties that could be used as INTEROP construct clauses, it is as if the INTEROP construct also contained those clauses, and the properties will be removed from the interoperability requirement set.
- Each appended argument is destroyed after the selected variant completes executions as if the INTEROP construct contained a DESTROY clause.

If the variant is invoked by a DISPATCH construct that contains an INTEROP clause with *n* variables specified, the first *n modifier*s specified in the APPEND_ARGS clause are ignored and replaced by the *n* variables specified in the INTEROP clause of the DISPATCH directive. The order of these *n* variables appearing in the argument list is the same order that they are specified in the INTEROP clause of the DISPATCH directive.

If there are *m modifier*s specified in the APPEND_ARG clause, and *m* > *n*, an argument for each of the remaining *m* - *n modifier*s in the APPEND_ARGS clause is constructed and appended to the end of the argument list in the same order in which they appear in the APPEND_ARGS clause.

Calling a procedure variant directly by *variant-proc-name* within an OpenMP* context that is different than the context specified in the MATCH clause is non-conforming.

Example

The DECLARE VARIANT directive in the module procedure `vecadd_base` identifies the procedure `vecadd_gpu_offload` as a variant that is to replace references to `vecadd_base` when called from a DISPATCH construct and a GEN device is available for offloading. Notice that `vecadd_base` does not have any dummy arguments, while `vecadd_gpu_offload` has a single C_PTR dummy argument.

```
MODULE vecadd
  INTEGER,PARAMETER  :: n = 1024
CONTAINS
  FUNCTION vecadd_gpu_offload (ptr) RESULT (res)
   USE,INTRINSIC :: ISO_C_BINDING, ONLY : c_ptr
   !$DEC ATTRIBUTES NOINLINE :: vecadd_gpu_offload
    TYPE (c_ptr)      :: ptr
```

```
    REAL              :: res
    REAL,DIMENSION(n) :: a, b
    INTEGER           :: k

!$omp TARGET PARALLEL DO REDUCTION (+: res) MAP(TO: a, b)
   DO k= 0, n - 1
     a(k) = k
     b(k) = k + 1
     res   = a(k) + b(k)
    END DO
!$omp END TARGET PARALLEL DO
    PRINT *, "GPU version of vecadd called"
  END FUNCTION vecadd_gpu_offload

  FUNCTION vecadd_base ()RESULT (res)
    !$DEC ATTRIBUTES NOINLINE :: vecadd_base
    !$OMP DECLARE VARIANT (vecadd_gpu_offload) &
    !$OMP&                ,MATCH (DEVICE = {ARCH (gen)} ))
    REAL              :: res
    REAL,DIMENSION(n) :: a, b
    INTEGER           :: k

!$omp PARALLEL DO REDUCTION (+: res)
   DO k = 1, n
      a(k) = k
      b(k) = k + 1
      res   = a(k) + b(k)
    END DO
!$omp END PARALLEL DO
    PRINT *, "CPU version of vecadd called"
  END FUNCTION vecadd_base
END MODULE vecadd

PROGRAM main
  USE vecadd
  REAL    :: result = 0.0

  !$OMP DISPATCH
  result = vecadd_base ()

  IF (result == 1048576.0) then
    PRINT *, "PASSED: correct results"
  ELSE
    PRINT *, "FAILED: incorrect results"
  ENDIF
END PROGRAM
```

DECODE

Statement: *Translates data from character to internal form. It is comparable to using internal files in formatted sequential READ statements.*

Syntax

```
DECODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]
```

c	Is a scalar integer expression. It is the number of characters to be translated to internal form.
f	Is a format identifier. An error occurs if more than one record is specified.
b	Is a scalar or array reference. If *b* is an array reference, its elements are processed in the order of subscript progression. *b* contains the characters to be translated to internal form.
i-var	Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
label	Is the label of an executable statement that receives control if an error occurs.
io-list	Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list receives the data after translation to internal form. The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the DECODE statement can translate depends on the data type of *b*. For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

Example

In the following example, the DECODE statement translates the 12 characters in A to integer form (as specified by the FORMAT statement):

```
     DIMENSION K(3)
     CHARACTER*12 A,B
     DATA A/'123456789012'/
     DECODE(12,100,A) K
100  FORMAT(3I4)
```

The 12 characters are stored in array K:

```
K(1) = 1234
K(2) = 5678
K(3) = 9012
```

READ
WRITE

ENCODE

DEFAULT Clause

Parallel Directive Clause: *Lets you specify a scope for all variables in the lexical extent of a parallel region.*

Syntax

```
DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE )
```

The specifications have the following effects:

- PRIVATE - Makes all named objects in the lexical extent of the parallel region, including common block variables but excluding THREADPRIVATE variables, private to a thread as if you explicitly listed each variable in a PRIVATE clause.
- FIRSTPRIVATE - Makes all variables in the construct that have implicitly determined data-sharing attributes firstprivate as if you explicitly listed each variable in a FIRSTPRIVATE clause.
- SHARED - Makes all named objects in the lexical extent of the parallel region shared among the threads in a team, as if you explicitly listed each variable in a SHARED clause. If you do not specify a DEFAULT clause, this is the default.
- NONE - Specifies that there is no implicit default as to whether variables are PRIVATE or SHARED. In this case, you must specify the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION property of each variable you use in the lexical extent of the parallel region.

You can specify only one DEFAULT clause in a PARALLEL directive. You can exclude variables from a defined default by using the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clauses.

Variables in THREADPRIVATE common blocks are not affected by this clause.

DEFINE and UNDEFINE

General Compiler Directives: *DEFINE creates a symbolic variable whose existence or value can be tested during conditional compilation. UNDEFINE removes a defined symbol.*

Syntax

```
!DIR$ DEFINE name[ = val]
```

```
!DIR$ UNDEFINE name
```

name	Is the name of the variable.
val	INTEGER(4). The value assigned to *name*.

DEFINE creates and UNDEFINE removes symbols for use with the IF (or IF DEFINED) compiler directive. Symbols defined with DEFINE directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.

To test whether a symbol has been defined, use the IF DEFINED (*name*) directive. You can assign an integer value to a defined symbol. To test the assigned value of *name*, use the IF directive. IF test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The DEFINE and UNDEFINE directives can appear anywhere in a program, enabling and disabling symbol definitions.

Example

```
!DIR$ DEFINE testflag
!DIR$ IF DEFINED (testflag)
   write (*,*) 'Compiling first line'
!DIR$ ELSE
   write (*,*) 'Compiling second line'
!DIR$ ENDIF
!DIR$ UNDEFINE testflag
```

DEFINE FILE

Statement: *Establishes the size and structure of files with relative organization and associates them with a logical unit number.*

Syntax

`DEFINE FILE u(m,n,U,asv) [,u(m,n,U,asv)] ...`

u	Is a scalar 32-bit integer constant or variable that specifies the logical unit number.
m	Is a scalar integer constant or variable that specifies the number of records in the file.
n	Is a scalar integer constant or variable that specifies the length of each record in 16-bit words (2 bytes). For files with record lengths greater than 2^{32} -1, the OPEN statement should be used.
U	Specifies that the file is unformatted (binary); this is the only acceptable entry in this position.
asv	Is a scalar integer variable, called the associated variable of the file. At the end of each direct access I/O operation, the record number of the next higher numbered record in the file is assigned to *asv*; *asv* must not be a dummy argument.

The DEFINE FILE statement is comparable to the OPEN statement. In situations where you can use the OPEN statement, OPEN is the preferable mechanism for creating and opening files.

The DEFINE FILE statement specifies that a file containing *m* fixed-length records, each composed of *n*16-bit words, exists (or will exist) on the specified logical unit. The records in the file are numbered sequentially from 1 through *m*.

A DEFINE FILE statement does not itself open a file. However, the statement must be executed before the first direct access I/O statement referring to the specified file. The file is opened when the I/O statement is executed.

If this I/O statement is a WRITE statement, a direct access sequential file is opened, or created if necessary.

If the I/O statement is a READ or FIND statement, an existing file is opened, unless the specified file does not exist. If a file does not exist, an error occurs.

The DEFINE FILE statement establishes the variable *asv* as the associated variable of a file. At the end of each direct access I/O operation, the Fortran I/O system places in *asv* the record number of the record immediately following the one just read or written.

The associated variable always points to the next sequential record in the file (unless the associated variable is redefined by an assignment, input, or FIND statement). So, direct access I/O statements can perform sequential processing on the file by using the associated variable of the file as the record number specifier.

Example

```
DEFINE FILE 3(1000,48,U,NREC)
```

In this example, the DEFINE FILE statement specifies that the logical unit 3 is to be connected to a file of 1000 fixed-length records; each record is forty-eight 16-bit words long. The records are numbered sequentially from 1 through 1000 and are unformatted.

After each direct access I/O operation on this file, the integer variable NREC will contain the record number of the record immediately following the record just processed.

OPEN

DELDIRQQ

Portability Function: *Deletes a specified directory.*

Module

USE IFPORT

Syntax

`result = DELDIRQQ (dir)`

dir	(Input) Character*(*). String containing the path of the directory to be deleted.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

Example

See the example for GETDRIVEDIRQQ.

CHANGEDRIVEQQ
UNLINK

DELETE

Statement: *Deletes a record from a relative file.*

Syntax

`DELETE ([UNIT=] io-unit[, REC=r][, ERR=label] [, IOSTAT=i-var])`

io-unit	Is an external unit specifier.
r	Is a scalar numeric expression indicating the record number to be deleted.
label	Is the label of the branch target statement that receives control if an error occurs.
i-var	Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

In a relative file, the DELETE statement deletes the direct access record specified by *r*. If REC= *r* is omitted, the current record is deleted. When the direct access record is deleted, any associated variable is set to the next record number.

The DELETE statement logically removes the appropriate record from the specified file by locating the record and marking it as a deleted record. It then frees the position formerly occupied by the deleted record so that a new record can be written at that position.

NOTE
You must use compiler option vms for READs to detect that a record has been deleted.

Example

The following statement deletes the fifth record in the file connected to I/O unit 10:

```
DELETE (10, REC=5)
```

Suppose the following statement is specified:

```
DELETE (UNIT=9, REC=10, IOSTAT=IOS, ERR=20)
```

The tenth record in the file connected to unit 9 is deleted. If an error occurs, control is transferred to the statement labeled 20, and a positive integer is stored in the variable IOS.

See Also

Data Transfer I/O Statements
Branch Specifiers
vms compiler option

DELFILESQQ

Portability Function: *Deletes all files matching the name specification, which can contain wildcards (* and ?).*

Module

USE IFPORT

Syntax

```
result = DELFILESQQ (files)
```

files	(Input) Character*(*). Files to be deleted. Can contain wildcards (* and ?).

Results

The result type is INTEGER(2). The result is the number of files deleted.

You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

Example

```
USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: "
len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
   WRITE(*,*) "Are you sure (Y/N)?"
   ch = GETCHARQQ()
   IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END
```

FINDFILEQQ

DEPEND Clause

Parallel Directive Clause: *Enforces additional constraints on the scheduling of a task or loop iterations by enabling dependences between sibling tasks in the task region.*

Syntax

It takes one of the following forms:

In Synchronization Directive !$OMP ORDERED

`DEPEND (SOURCE)` *-or-*

`DEPEND (SINK:`*vec*`)`

The above forms of the DEPEND clause have been deprecated and replaced by the DOACROSS clause in the ORDERED construct.

In all other directives:

`DEPEND ([`*depend-modifier*`,] `*dependence-type*` : `*locator-list*`)`

depend-modifier	ITERATOR clause modifier
dependence-type	Can be any one of the following clauses: IN, OUT, or INOUT, MUTEXINOUTSET, INOUTSET, or DEPOBJ. Clauses MUTEXINOUTSET, INOUTSET, and DEPOBJ are only supported for ifx.
locator	If *dependence-type* is DEPOBJ, *locator* must be a depend object in the initialized state. Otherwise, it is a variable or a non-zero length array section. Zero-sized arrays and common block names are not permitted as *locator-list* items.

Any *locator*-list item used in a DEPEND clause of the same task or sibling tasks must indicate identical storage or disjoint storage; partial overlap is not permitted. Two locators match if their storage locations are the same, or if the OpenMP reserved locator symbol OMP_ALL_MEMORY appears in the list; in that case, all list items match.

If *dependence-type* is OUT or INOUT, *locator* must not be the OpenMP reserved locator OMP_ALL_MEMORY.

The behavior is undefined in these cases:

- If *locator* has the POINTER attribute and its association status is disassociated or undefined
- If *locator* has the ALLOCATABLE attribute and its allocation status is unallocated

Note that this enforced task dependence establishes a synchronization of accesses to each *locator*-list item performed by a dependent task, with respect to accesses to the same *locator*-list item performed by any previous tasks. You must properly synchronize access with respect to other concurrent accesses to each *locator*-list item.

`SOURCE` Specifies the satisfaction of cross-iteration dependences that arise from the current iteration.

`SINK` Specifies a cross-iteration dependence, where the iteration vector *vec* indicates the iteration that satisfies the dependence.

`vec` Is the iteration vector. It has the form:

$$x_1[\pm d_1], x_2[\pm d_2], \ldots, x_n[\pm d_n]$$

where *n* is the value specified by the ORDERED clause in the DO loop directive, x_i denotes the loop iteration variable of the *i*-th nested loop associated with the loop directive, and d_i is a non-negative integer scalar constant.

If *vec* does not occur in the iteration space, the DEPEND clause is ignored. Note that if *vec* does not indicate a lexicographically earlier iteration, it can cause a deadlock.

For a *vec* element form of $x_i + d_i$ or $x_i - d_i$, the expression $x_i + d_i$ or $x_i - d_i$ for any value of the integer loop iteration variable x_i that can encounter the ordered construct must be computable in the loop iteration variable's type without overflow.

Rules related to sibling task dependency:

- The generated task is a dependent task of the sibling task if any of the following are true:
  - If one or more *locator*-list items specified in *dependence-type* IN matches a *locator*-list item appearing in any of the following DEPEND clause *dependence-type*s on a construct that previously generated a sibling task: OUT, INOUT, MUTEXINOUTSET, or INOUTSET.
  - If one or more *locator*-list items specified in *dependence-type* OUT or INOUT matches a *locator*-list item appearing in any of the following DEPEND clause *dependence-type*s on a construct that previously generated a sibling task: IN, OUT, INOUT, MUTEXINOUTSET, or INOUTSET.
  - If one or more *locator*-list items specified in *dependence-type* INOUTSET matches a *locator*-list item appearing in any of the following DEPEND clause *dependence-type*s on a construct that previously generated a sibling task: IN, OUT, INOUT, or MUTEXINOUTSET.

- If one or more *locator*-list items specified in *dependence-type* MUTEXINOUTSET matches a *locator*-list item appearing in any of the following DEPEND clause *dependence-type*s on a construct that previously generated a sibling task: IN, OUT, INOUT, or INOUTSET.

- The sibling tasks are mutually exclusive if the following is true:
  - If one or more *locator*-list items specified in *dependence-type* MUTEXINOUTSET matches a *locator*-list item appearing in a DEPEND clause with MUTEXINOUTSET *dependence-type* on a different task generating construct and both constructs generate sibling tasks.

When *dependence-type* is DEPOBJ, the locators must all be depend objects. The *dependence-type*s are derived from the depend objects. For each depend object, the behavior is as if the current construct contained the DEPEND clause of the most recently executed DEPOBJ construct that initialized or updated the depend object.

If a DEPEND clause appears in a TARGET or TARGET UPDATE directive, it is treated as if it had appeared on the implicit task construct that encloses the TARGET construct.

See Also

DEPOBJ

DEPOBJ

OpenMP* Fortran Compiler Directive: *Initializes, updates, or uninitializes an OpenMP depend object.*
This feature is only available for ifx.

Syntax

`!$OMP DEPOBJ(`*depend-object*`) `*clause*

depend-object

Is a scalar integer variable with kind type OMP_DEPEND_KIND, a named integer kind type constant defined in module `omp_lib`.

clause

Is one of the following:

- `DEPEND` (*dependence-type* : *locator*)

  Sets the state of *depend-object* to initialized with a value that represents the dependence specified. *depend-object* must be in an uninitialized state.

  dependence-type and *locator* are as described in the DEPEND clause with the following exceptions:

  - *dependence-type* must not specify the SOURCE or SINK dependence type.
  - The DEPEND clause of a DEPOBJ construct can contain only one *locator*.

- `DESTROY` - this form is deprecated

  `DESTROY` (*destroy-var*)

  Sets the state of *destroy-var* to be uninitialized.

  The *destroy-var* must be a scalar integer variable with kind type OMP_DEPEND_KIND and be in an initialized state or the behavior of the program is unspecified. *destroy-var* must be the same variable as *depend-object*.

  When DESTROY is specified, the *interop-type* is the *interop-type* used to initialize *destroy-var*. Argument *interop-type* is defined in the description of directive INTEROP.

After execution of a DEPOBJ directive with a DESTROY clause, the object specified by *destroy-var* is unusable until it has been initialized by execution of an INTEROP construct.

If *destroy-var* does not appear, it is as if *destroy-var* appeared and is the same variable as specified for *depend-object*. Note that the form DESTROY with no argument has been deprecated in OpenMP* specification 5.2.

- `UPDATE` (*dependence-type*)

  Changes the *dependence-type* of an initialized *depend-object* to the *dependence-type* specified. *depend-object* must be in an initialized state. *dependence-type* can not specify SOURCE, SINK, or DEPOBJ dependence types.

Description

A depend object allows dynamic user-computed dependencies to be used in DEPEND clauses.

Depend objects must only be modified in a DEPOBJ construct, and referenced in a DEPEND clause. Any other use of a variable that is a depend object makes the program a non-conforming OpenMP program. Depend objects have two states, uninitialized and initialized. Depend objects have an initial state of uninitialized.

The DEPOBJ directive is a standalone construct; it does not affect any loop-nest or structured-block following it. The binding thread set for a DEPOBJ regions is the thread that encounters it.

Syntax Rules for Compiler Directives
INTEROP

DEVICE Clause

Parallel Directive Clause: *Specifies the target device for a processor control directive like TARGET.*

Syntax

`DEVICE (`*`scalar-integer-expression`*`)`

`scalar-integer-expression`	Is an integer expression. It must evaluate to a positive scalar integer value.

At most one DEVICE clause can appear in a directive that allows the clause.

If DEVICE is not specified, the default device is determined by the internal control variable (ICV) named `device-num-var`.

DEVICE_TYPE Clause

Parallel Directive Clause: *Specifies whether a version of a procedure or a copy of a data entity is to be available on a HOST device, a non-HOST device, or both. This feature is only available for ifx.*

Syntax

`DEVICE_TYPE (`*`device`*`)`

`device`	Is HOST, NOHOST, or ANY.

The DEVICE_TYPE clause specifies whether a variable, COMMON block, or procedure is to be made available on a HOST device, a non-HOST device, or both device types.

If HOST is specified, only a HOST version of the data or procedure is available. At this time, ifx will produce an error if HOST is specified because there is only support for device compilation.

NOHOST indicates that only a device version of the data or procedure is made available.

ANY specifies that both a device and a host version of the data or procedure are made available. At this time, specifying ANY results in a warning that only device compilation is supported.

If a directive that accepts a DEVICE_TYPE clause does not specify the DEVICE_TYPE clause, the behavior is as if DEVICE_TYPE (ANY) had appeared.

DFLOAT

Elemental Intrinsic Function (Generic): *Converts an integer to double-precision real type.*

Syntax

```
result = DFLOAT (a)
```

a (Input) Must be of type integer.

Results

The result type is double-precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

Specific Name [1]	Argument Type	Result Type [2]
	INTEGER(1)	REAL(8)
DFLOTI	INTEGER(2)	REAL(8)
DFLOTJ	INTEGER(4)	REAL(8)
DFLOTK	INTEGER(8)	REAL(8)

[1]These specific functions cannot be passed as actual arguments.

[2]The setting of compiler options specifying double size can affect DFLOAT.

Example

DFLOAT (-4) has the value -4.0.

See Also

REAL

DFLOATI, DFLOATJ, DFLOATK

Portability Functions: *Convert an integer to double-precision real type.*

Module

USE IFPORT

Syntax

```
result = DFLOATI (i)
result = DFLOATJ (j)
```

```
result = DFLOATK (k)
```

i	(Input) Must be of type INTEGER(2).
j	(Input) Must be of type INTEGER(4).
k	(Input) Must be of type INTEGER(8).

Results

The result type is double-precision real (REAL(8) or REAL*8).

See Also

DFLOAT

DIGITS

Inquiry Intrinsic Function (Generic): *Returns the number of significant digits for numbers of the same type and kind parameters as the argument.*

Syntax

```
result = DIGITS (x)
```

x	(Input) Must be of type integer or real; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

The result has the value *q* if *x* is of type integer; it has the value *p* if *x* is of type real. Integer parameter *q* is defined in Model for Integer Data; real parameter *p* is defined in Model for Real Data.

Example

If *x* is of type REAL(4), DIGITS(x) has the value 24.

See Also

EXPONENT
RADIX
FRACTION
Data Representation Models

DIM

Elemental Intrinsic Function (Generic): *Returns the difference between two numbers (if the difference is positive).*

Syntax

```
result = DIM (x, y)
```

x	(Input) Must be of type integer or real.
y	(Input) Must have the same type and kind parameters as *x*.

Results

The result type and kind are the same as *x*. The value of the result is *x*- *y* if *x* is greater than *y*; otherwise, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

Specific Name	Argument type	Result Type
BDIM	INTEGER(1)	INTEGER(1)
IIDIM[1]	INTEGER(2)	INTEGER(2)
IDIM [2]	INTEGER(4)	INTEGER(4)
KIDIM	INTEGER(8)	INTEGER(8)
DIM	REAL(4)	REAL(4)
DDIM	REAL(8)	REAL(8)
QDIM	REAL(16)	REAL(16)

[1]Or HDIM.

[2]Or JIDIM. For compatibility, IDIM can also be specified as a generic function for integer types.

Example

DIM (6, 2) has the value 4.

DIM (-4.0, 3.0) has the value 0.0.

The following shows another example:

```
INTEGER i
REAL r
REAL(8) d
i = IDIM(10, 5)            ! returns 5
r = DIM (-5.1, 3.7)        ! returns 0.0
d = DDIM (10.0D0, -5.0D0)  ! returns 15.0D0
```

Argument Keywords in Intrinsic Procedures

DIMENSION

Statement and Attribute: *Specifies that an object is an array, and defines the shape of the array.*

Syntax

The DIMENSION attribute can be specified in a type declaration statement or a DIMENSION statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] DIMENSION (*a-spec*) [, *att-ls*] :: *a*[(*a-spec*)][, *a*[(*a-spec*)]] ...

Statement:

DIMENSION [::]*a*(*a-spec*) [, *a*(*a-spec*)] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
a-spec	Is an array specification. It can be any of the following: • An explicit-shape specification; for example, a(10,10)

- An assumed-shape specification; for example, a(:)
- A deferred-shape specification; for example, a(:,:)
- An assumed-size specification; for example, a(10,*)
- An assumed-rank specification; for example, a(..)
- An implicit-shape specification; for example, a(*)

For more information on array specifications, see Declaration Statements for Arrays.

In a type declaration statement, any array specification following an array overrides any array specification following DIMENSION.

a Is the name of the array being declared.

Description

The DIMENSION attribute allocates a number of storage elements to each array named, one storage element to each array element in each dimension. The size of each storage element is determined by the data type of the array.

The total number of storage elements assigned to an array is equal to the number produced by multiplying together the number of elements in each dimension in the array specification. For example, the following statement defines ARRAY as having 16 real elements of 4 bytes each and defines MATRIX as having 125 integer elements of 4 bytes each:

```
DIMENSION ARRAY(4,4), MATRIX(5,5,5)
```

An array can also be declared in the following statements: ALLOCATABLE, AUTOMATIC, COMMON, POINTER, STATIC, TARGET.

Example

The following examples show type declaration statements specifying the DIMENSION attribute:

```
REAL, DIMENSION(10, 10) :: A, B, C(10, 15)  ! Specification following C
                                            ! overrides the one following
                                            ! DIMENSION
REAL(8), DIMENSION(5,-2:2) :: A,B,C
```

The following are examples of the DIMENSION statement:

```
DIMENSION BOTTOM(12,24,10)
DIMENSION X(5,5,5), Y(4,85), Z(100)
DIMENSION MARK(4,4,4,4)
SUBROUTINE APROC(A1,A2,N1,N2,N3)
DIMENSION A1(N1:N2), A2(N3:*)
CHARACTER(LEN = 20) D
DIMENSION A(15), B(15, 40), C(-5:8, 7), D(15)
```

You can declare arrays by using type statements and ALLOCATABLE attributes and statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:,:)
REAL(8), ALLOCATABLE, DIMENSION( :, :, : ) :: E
```

You can declare an implicit-shape constant array by using a type statement and a PARAMETER attribute, for example:

```
INTEGER, PARAMETER :: R(*) = [1,2,3]
```

You can also declare arrays by using type and ALLOCATABLE statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:,:)
REAL(8), ALLOCATABLE, DIMENSION( :, :, : ) :: E
```

You can specify both the upper and lower dimension bounds. If, for example, one array contains data from experiments numbered 28 through 112, you could dimension the array as follows:

```
DIMENSION experiment(28:112)
```

Then, to refer to the data from experiment 72, you would reference experiment(72).

Array elements are stored in column-major order: the leftmost subscript is incremented first when the array is mapped into contiguous memory addresses. For example, consider the following statements:

```
INTEGER(2) a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

These are equivalent to:

```
INTEGER(2) a
DIMENSION a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

If `a` is placed at location decimal 1000 in memory, the preceding DATA statement produces the following mapping.

Array element	Address (decimal)	Value
a(1,0)	1000	1
a(2,0)	1002	2
a(1,1)	1004	3
a(2,1)	1006	4
a(1,2)	1008	5
a(2,2)	100A	6

The following DIMENSION statement defines an assumed-size array in a subprogram:

```
DIMENSION data (19,*)
```

At execution time, the array data is given the size of the corresponding array in the calling program.

The following program fragment dimensions two arrays:

```
 ...
 SUBROUTINE Subr (matrix, rows, vector)
 REAL MATRIX, VECTOR
 INTEGER ROWS
 DIMENSION MATRIX (ROWS,*), VECTOR (10),
+  LOCAL (2,4,8)
 MATRIX (1,1) = VECTOR (5)
 ...
```

DISPATCH

OpenMP* Fortran Compiler Directive: *Determines whether a variant of a procedure is called for a given function or subroutine call. This feature is only available for ifx.*

Syntax

```
!$OMP DISPATCH [clause[[,] clause]... ]
   statement
[!$OMP END DISPATCH]
```

clause

Is one or more of the following:

- DEPEND ([depend-modifier,] dependence-type : locator-list)

  Adds the DEPEND properties to the interoperability set.
- DEVICE (scalar-integer-expression)

  Causes the value of the `default-device-var` ICV of the generated task to be set to the value of the DEVICE clause expression.
- INTEROP (*list*)

  Specifies *interop*-variables to be substituted for the appended *interop* arguments constructed by the APPEND_ARGS clause in the corresponding DECLARE VARIANT declaration when variant dispatch occurs.

  The *list* items are integer scalar variables with kind type OMP_INTEROP_TYPE.

  If there are *n* variables in the list, the first *n modifier*s in the APPEND_ARGS clause of the associated DECLARE VARIANT directive are skipped, and the *n* variables are passed as the first *n* appended arguments, in the order that they appear in *list*.

  If the INTEROP clause appears in the DISPATCH directive, the corresponding DECLARE VARIANT directive must have an APPEND_ARGS clause with at least as many *interop-type*s listed as there are *list* items in the INTEROP clause in the DISPATCH directive.

  If the INTEROP directive appears with only one list item and the DEVICE clause does not appear, it is as if DEVICE was specified with the device number property of the listed *interop-var*.

  The DEVICE clause is required if there is more than one *list* item specified in the INTEROP clause.
- IS_DEVICE_PTR (list)

  Identifies its list items as device pointers. The IS_DEVICE_PTR property for each list item is added to the interoperability requirement set.

  Each IS_DEVICE_PTR list item must be of type C_PTR from the intrinsic module ISO_C_BINDING
- NOCONTEXT (*scalar-logical-expression*)

If a NOCONTEXT clause appears and the scalar-logical-expression evaluates to .TRUE., the DISPATCH construct is not added to the construct set of the OpenMP context.

If the NOCONTEXT expression evaluates to .FALSE., the DISPATCH directive is added to the OpenMP* context.

- NOVARIANTS (*scalar-logical-expression*)

  If a NOVARIANTS clause appears, and the scalar-logical-expression evaluates to .TRUE., no function variant is selected for execution as the target-call, even if one would otherwise have been selected.

  If the NOVARIANTS expression evaluates to .FALSE., and a variant exists that specified an OpenMP* context in the MATCH clause that matches the current context, the variant is called
- NOWAIT

  Adds the NOWAIT property to the interoperability requirement set.

Variables used in the expression of a NOVARIANTS clause or a NOCONTEXT clause are implicitly referenced in all enclosing contexts of the DISPATCH directive.

Only one of each of the following clauses is permitted in a DISPATCH directive: NOWAIT, NOCONTEXT, and NOVARIANT.

statement

Is a Fortran statement with one of these forms:

- var = *target_proc* ([argument-list])
- CALL *target_proc* [([argument-list])]

target_proc must be a procedure name; it cannot be a procedure pointer.

The DISPATCH directive creates an explicit task around the associated code as if a TASK construct was present. Properties added to the interoperability requirement set can be removed by other directives. The task will be an included task if the interoperability requirement set does not contain a NOWAIT property.

If the interoperability requirements set contains DEPEND properties, it is as if the TASK construct contained the corresponding DEPEND clauses.

DISTRIBUTE

OpenMP* Fortran Compiler Directive: *Specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct.*

Syntax

```
!$OMP DISTRIBUTE [clause[[,] clause]... ]
   do-loop
[!$OMP END DISTRIBUTE]
```

clause

Is one of the following:

- ALLOCATE ([allocator :] list)
- COLLAPSE (n)
- DIST_SCHEDULE (*kind* [, *chunk-size*])

  Specifies how iterations are divided.

  The *kind* must be STATIC (see SCHEDULE in DO Directive).

  The *chunk-size* must be a positive scalar integer expression. If specified, iterations are divided into chunks of size *chunk-size*. Chunks are assigned round-robin to the teams of the parallel region in the order of the team numbers.

  When no *chunk-size* is specified, iterations are divided into chunks that are approximately equal in size. In this case, at most one chunk is distributed to each team of the parallel region.
- FIRSTPRIVATE (list)
- LASTPRIVATE ([CONDITIONAL:] list)
- ORDER ([order-modifier :] CONCURRENT) (ifx only)
- PRIVATE (list)

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

If an END DO directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The DISTRIBUTE construct inherits the restrictions of the loop construct.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If more than one loop is associated with the DISTRIBUTE construct, then the iterations of all associated loops are collapsed into one larger iteration space. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

You cannot branch out of a DO loop associated with a DISTRIBUTE directive.

The binding thread set for a DISTRIBUTE construct is the set of primary threads created by a TEAMS construct. A DISTRIBUTE region binds to the innermost enclosing team's parallel region. Only the threads that execute the binding team's parallel region participate in the execution of the loop iterations. A DISTRIBUTE construct must be closely nested in a team's region.

If used, the END DISTRIBUTE directive must appear immediately after the end of the loop. If you do not specify an END DISTRIBUTE directive, an END DISTRIBUTE directive is assumed at the end of the *do-loop*.

The DISTRIBUTE construct is associated with loop iterations that follow the directive. The iterations are distributed across the primary threads of all teams that execute the team's parallel region to which the DISTRIBUTE region binds.

A list item may appear in a FIRSTPRIVATE or LASTPRIVATE clause but not both.

DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: *Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.*

Syntax

```
!$OMP DISTRIBUTE PARALLEL DO [clause[[,] clause]... ]
   do-loop
[!$OMP END DISTRIBUTE PARALLEL DO]
```

clause — Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO directives with identical meanings and restrictions except for ORDERED and LINEAR .

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO directive is not specified, an END DISTRIBUTE PARALLEL DO directive is assumed at the end of *do-loop*.

This directive specifies a composite construct.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DISTRIBUTE PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: *Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.*

Syntax

```
!$OMP DISTRIBUTE PARALLEL DO SIMD [clause[[,] clause]... ]
   do-loop
[!$OMP END DISTRIBUTE PARALLEL DO SIMD]
```

clause — Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO SIMD directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of *do-loop*.

This directive specifies a composite construct.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DISTRIBUTE POINT

General Compiler Directive: *Specifies loop distribution. It suggests a location at which a DO loop can be split.*

Syntax

```
!DIR$ DISTRIBUTE POINT
```

Loop distribution causes large loops to be distributed (split) into smaller ones. The resulting loops contain a subset of the instructions from the initial loop. Loop distribution can enable software pipelining to be applied to more loops. It can also reduce register pressure and improve both instruction and data cache use.

If the directive is placed before a loop, the compiler will determine where to distribute; data dependencies are observed.

If the directive is placed inside a loop, the distribution is performed after the directive and any loop-carried dependencies are ignored. Currently only one distribute directive is supported if the directive is placed inside the loop.

Example

```
!DIR$ DISTRIBUTE POINT
   do i =1, m
     b(i) = a(i) +1
     ....
     c(i) = a(i) + b(i) ! Compiler will decide
     ! where to distribute.
     ! Data dependencies are
     ! observed
     ....
     d(i) = c(i) + 1
   enddo
   do i =1, m
     b(i) = a(i) +1
     ....
!DIR$ DISTRIBUTE POINT
     call sub(a, n)! Distribution will start here,
```

```
    ! ignoring all loop-carried
    ! depedencies
    c(i) = a(i) + b(i)
    ....
    d(i) = c(i) + 1
  enddo
```

General Compiler Directives

Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops

DISTRIBUTE SIMD

OpenMP* Fortran Compiler Directive: *Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.*

Syntax

```
!$OMP DISTRIBUTE SIMD [clause[[,] clause]... ]
   do-loop
[!$OMP END DISTRIBUTE SIMD]
```

clause
Can be any of the clauses accepted by the DISTRIBUTE or SIMD directives with identical meanings and restrictions.

do-loop
Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE SIMD directive is not specified, an END DISTRIBUTE SIMD directive is assumed at the end of *do-loop*.

This directive specifies a composite construct.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DNUM

Elemental Intrinsic Function (Specific): *Converts a character string to a REAL(8) value. This function cannot be passed as an actual argument.*

Syntax

```
result = DNUM (i)
```

i (Input) Must be of type character.

Results

The result type is REAL(8). The result value is the double-precision real value represented by the character string *i*.

Example

DNUM ("3.14159") has the value 3.14159 of type REAL(8).

The following sets x to 311.0:

```
CHARACTER(3) i
DOUBLE PRECISION x
i = "311"
x = DNUM(i)
```

DO Directive

OpenMP* Fortran Compiler Directive: *Specifies that the iterations of the immediately following DO loop must be executed in parallel.*

Syntax

```
!$OMP DO [clause[[,] clause] ... ]
   do_loop
[!$OMP END DO [NOWAIT]]
```

clause Is one of the following:

- ALLOCATE ([allocator :] list)
- COLLAPSE (n)
- FIRSTPRIVATE (list)
- LASTPRIVATE ([CONDITIONAL:] list)
- LINEAR (linear-list [: linear-modifier [, linear-modifier]])
- NOWAIT
- ORDER ([order-modifier :] CONCURRENT) (ifx only)
- ORDERED [(*n*)]

  Must be used if ordered sections are contained in the dynamic extent of the DO directive. For more information about ordered sections, see the ORDERED directive.

  If *n* is specified, it must be a positive scalar integer constant expression.

  The ORDERED clause must not appear in the worksharing-loop (DO) directive if the loops associated with the worksharing-loop construct include loops generated as the result of a TILE directive, or if the ORDER clause is specified.
- PRIVATE (list)
- REDUCTION ([reduction-modifier,]reduction-identifier : list)

  If the REDUCTION clause contains the INSCAN reduction-modifier, the DO directive must not contain an ORDERED or a SCHEDULE clause.
- SCHEDULE ([*modifier* [, *modifier*]:] *kind*[, *chunk_size*])

Specifies how iterations of the DO loop are divided among the threads of the team. *chunk_size* must be a loop invariant positive scalar integer expression. The value of *chunk_size* must be the same for all threads in the team. The following *kind*s are permitted, only some of which allow the optional parameter *chunk_size*:

Kinds	Effect
STATIC	Divides iterations into contiguous pieces by dividing the number of iterations by the number of threads in the team. Each piece is then dispatched to a thread before loop execution begins. If *chunk_size* is specified, iterations are divided into pieces of a size specified by *chunk_size*. The pieces are statically dispatched to threads in the team in a round-robin fashion in the order of the thread number.
DYNAMIC	Can be used to get a set of iterations dynamically. It defaults to 1 unless *chunk_size* is specified. If *chunk_size* is specified, the iterations are broken into pieces of a size specified by *chunk*. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations.
GUIDED	Can be used to specify a minimum number of iterations. It defaults to 1 unless *chunk_size* is specified. If *chunk_size* is specified, the chunk size is reduced exponentially with each succeeding dispatch. The *chunk_size* specifies the minimum number of iterations to dispatch each time. If there are less than *chunk_size* iterations remaining, the rest are dispatched.
AUTO[1]	Delegates the scheduling decision until compile time or runtime. The schedule is

Kinds	Effect
	processor dependent. The programmer gives the implementation the freedom to choose any possible mapping of iterations to threads in the team.
RUNTIME[1]	Defers the scheduling decision until runtime. You can choose a schedule type and chunk size at runtime by using the environment variable OMP_SCHEDULE.

[1]No *chunk_size* is permitted for this type.

At most one SCHEDULE clause can appear. If the SCHEDULE clause is not used, the default schedule type is STATIC.

modifier can be one of the following:

Modifier	Effect
MONOTONIC	Each thread executes the chunks that it is assigned in increasing logical iteration order.
NONMONOTONIC[1]	Chunks are assigned to threads in any order and the behavior of an application that depends on any execution order of the chunks is unspecified.
SIMD	When *do_loop* is associated with an OMP SIMD construct, the *chunk_size* for all chunks except the first and last chunks is: *new_chunk_size* = (*chunk_size* / *simd_width*)**simd_width* where *simd_width* is an implementation-defined value. The first chunk will have at least *new_chunk_size* iterations unless it is also the last chunk. The last chunk may have fewer iterations than *new_chunk_size*. If SIMD is specified and the loop is not associated with an OMP SIMD construct, the modifier is ignored.

Modifier	Effect
[1]NONMONOTONIC can only be specified with SCHEDULE(DYNAMIC) or SCHEDULE(GUIDED).	

If the schedule kind is STATIC or if the ORDERED clause appears, and if MONOTONIC does not appear, the effect will be as if MONOTONIC was specified. NONMONOTONIC cannot be specified if the ORDERED clause appears. Either MONOTONIC or NONMONTONIC can appear but not both.

modifier cannot appear if the LINEAR clause appears.

The SIMD *modifier* can be used with MONOTONIC or NONMONOTONIC in either order. The SIMD *modifier* and the MONOTONIC *modifier* can be used with all *kind*s.

do_loop Is a DO iteration (an iterative DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO directive.

The binding thread set for a DO construct is the current team. A DO loop region binds to the innermost enclosing parallel region.

If used, the END DO directive must appear immediately after the end of the loop. If you do not specify an END DO directive, an END DO directive is assumed at the end of the DO loop.

If you specify NOWAIT, threads do not synchronize at the end of the parallel loop. Threads that finish early proceed straight to the instruction following the loop without waiting for the other members of the team to finish the DO directive.

Parallel DO loop control variables are block-level entities within the DO loop. If the loop control variable also appears in the LASTPRIVATE list of the parallel DO, it is copied out to a variable of the same name in the enclosing PARALLEL region. The variable in the enclosing PARALLEL region must be SHARED if it is specified in the LASTPRIVATE list of a DO directive.

Only a single SCHEDULE, COLLAPSE, or ORDERED clause can appear in a DO directive.

ORDERED (*n*) specifies how many loops are associated with the DO directive and it specifies that those associated loops form a doacross loop nest. *n* does not affect how the logical iteration space is divided.

If you specify COLLAPSE (M) ORDERED (N) for loops nested K deep, the following rules apply:

- If either M > K or N > K, the behavior is unspecified.
- N must be greater than M

A LINEAR clause or an ORDERED (*n*) clause can be specified in a DO directive, but not both.

DO directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END DO directive is optional:

```
!$OMP PARALLEL
!$OMP DO
      DO I=1,N
        B(I) = (A(I) + A(I-1)) / 2.0
      END DO
!$OMP END DO
!$OMP END PARALLEL
```

If there are multiple independent loops within a parallel region, you can use the NOWAIT keyword in the END DO directive, or the NOWAIT clause in the DO directive, to avoid the implied BARRIER at the end of the DO directive, as follows:

```
!$OMP PARALLEL
!$OMP DO
      DO I=2,N
        B(I) = (A(I) + A(I-1)) / 2.0
      END DO
!$OMP END DO NOWAIT
!$OMP DO
      DO I=1,M
        Y(I) = SQRT(Z(I))
      END DO
!$OMP END DO NOWAIT
!$OMP END PARALLEL
```

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. Such programs must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially, as follows:

```
!$OMP PARALLEL
!$OMP DO LASTPRIVATE(I)
      DO I=1,N
        A(I) = B(I) + C(I)
      END DO
!$OMP END PARALLEL
      CALL REVERSE(I)
```

In this case, the value of I at the end of the parallel region equals N+1, as in the sequential case.

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
      DO I=LB,UB,ST
        CALL WORK(I)
      END DO
      ...
      SUBROUTINE WORK(K)
!$OMP ORDERED
      WRITE(*,*) K
!$OMP END ORDERED
```

In the next example, the loops over J1 and J2 are collapsed and their iteration space is executed by all threads of the current team:

```
!$OMP DO COLLAPSE(2) PRIVATE(J1, J2, J3)
    DO J1 = J1_L, J1_U, J1_S
        DO J2 = J2_L, J2_U, J2_S
            DO J3 = J3_L, J3_U, J3_S
                CALL BAR(A, J1, J2, J3)
            ENDDO
        ENDDO
    ENDDO
!$OMP END DO
```

DO Statement

Statement: *Marks the beginning of a DO construct. The DO construct controls the repeated execution of a block of statements or constructs. This repeated execution is called a loop.*

Syntax

A DO construct takes one of the following forms:

Block Form:

```
[name:] DO [label[, ] ] [loop-control]
   block
[label] term-stmt
```

Non-block Form:

```
DO label [,] [loop-control]
   block
[label] ex-term-stmt
```

name	(Optional) Is the name of the DO construct.
label	(Optional) Is a statement label identifying the terminal statement.
loop-control	Is one of the following: • a loop iteration (see Iteration Loop Control) • WHILE (see the DO WHILE statement) • CONCURRENT (see the DO CONCURRENT statement)
block	Is a sequence of zero or more statements or constructs that make up the DO range.
term-stmt	Is the terminal statement for the block form of the construct.
ex-term-stmt	Is the terminal statement for the non-block form of the construct.

Description

The terminal statement (*term-stmt*) for a block DO construct is an END DO or CONTINUE statement. If the block DO statement contains a label, the terminal statement must be identified with the same label. If no label appears, the terminal statement must be an END DO statement.

If a construct name is specified in a block DO statement, the same name must appear in the terminal END DO statement. If no construct name is specified in the block DO statement, no name can appear in the terminal END DO statement.

The terminal statement (*ex-term-stmt*) for a non-block DO construct is an executable statement (or construct) that is identified by the label specified in the non-block DO statement. A non-block DO construct can share a terminal statement with another non-block DO construct. A block DO construct cannot share a terminal statement.

The following cannot be terminal statements for non-block DO constructs:

- CONTINUE (allowed if it is a shared terminal statement)
- CYCLE
- END (for a program or subprogram)
- EXIT
- GO TO (unconditional or assigned)
- Arithmetic IF
- RETURN
- STOP

The non-block DO construct is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The labeled form of a DO loop is an obsolescent feature in the Fortran Standard.

Example

The following example shows a simple block DO construct (contains no iteration count or DO WHILE statement):

```
DO
  READ *, N
  IF (N == 0) STOP
  CALL SUBN
END DO
```

The DO block executes repeatedly until the value of zero is read. Then the DO construct terminates.

The following example shows a named block DO construct:

```
LOOP_1: DO I = 1, N
          A(I) = C * B(I)
        END DO LOOP_1
```

The following example shows a nonblock DO construct with a shared terminal statement:

```
    DO 20 I = 1, N
    DO 20 J = 1 + I, N
20 RESULT(I,J) = 1.0 / REAL(I + J)
```

The following two program fragments are also examples of DO statements:

```
C   Initialize the even elements of a 20-element real array
    DIMENSION array(20)
    DO j = 2, 20, 2
      array(j) = 12.0
    END DO
```

```
C
C   Perform a function 11 times
    DO k = -30, -60, -3
      int = j / 3
      isb = -9 - k
      array(isb) = MyFunc (int)
    END DO
```

The following shows the final value of a DO variable (in this case 11):

```
   DO j = 1, 10
     WRITE (*, '(I5)') j
   END DO
   WRITE (*, '(I5)') j
```

DO CONCURRENT

Statement: *Specifies that there are no data dependencies between the iterations of a DO loop.*

Syntax

The DO CONCURRENT statement takes the following form:

```
[name:] DO [label [,]] CONCURRENT concurrent-header [locality-spec]
   block
[END DO [name]]
```

name	(Optional) Is the name of the DO CONCURRENT construct.
concurrent-header	Is ([*type* ::] *concurrent-spec* [, *mask-expr*]) If *type* appears, the *index-name* has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit. If *type* is omitted, the *index-name* must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.
type	(Optional) Is an integer data type.
concurrent-spec	Is an assignment using a triplet specification in the form *index-name* = *concurrent-limit* : *concurrent-limit* [: *concurrent-step*]
index-name	Is a named scalar variable of type integer. It becomes defined when the index-name value set is evaluated. It has the scope of the construct.

The *index-name* of a contained FORALL or DO CONCURRENT construct must not be the same as an *index-name* of any of its containing FORALL or DO CONCURRENT constructs.

concurrent-limit Is a scalar integer expression.

concurrent-step (Optional) Is a scalar integer expression.

mask-expr (Optional) Is a masked expression that is scalar and of type logical.

Any procedure referenced in *mask-expr* must be pure, including one referenced by a defined operator.

index-name can appear in *mask-expr*. The set of index values to be executed is the set of all *index-name* values for which *mask-expr* is true.

label (Optional) Is a label specifying an executable statement in the same program unit.

locality-spec (Optional) Can be any of the following:

- DEFAULT (NONE)

  You can specify DEFAULT (NONE) only once in a DO CONCURRENT statement. If specified, any variable or construct entity that is accessible in the scope containing the DO CONCURRENT statement that appears in the block of the DO CONCURRENT construct must have its locality explicitly specified.
- LOCAL (*variable-name-list*)
- LOCAL_INIT (*variable-name-list*)
- REDUCE (*reduction-oper* : *variable-name-list*)

  reduction-oper is one of the intrinsic binary-reduction-operators +, *, .AND., .OR., .EQV., or .NEQV., or one of the intrinsic function-reduction-operator names IAND, IEOR, IOR, MAX or MIN.

  A variable in *variable-name-list* cannot be coindexed, be an assumed-size array, or have the ASYNCHRONUS, INTENT(IN), OPTIONAL, or VOLATILE attribute. It must be of an intrinsic type that is compatible with the intrinsic *reduction-oper*.
- SHARED (*variable-name-list*)

  References in a DO CONCURRENT construct to a SHARED variable are references to the variable in the innermost construct or scope containing the DO CONCURRENT construct.

  If the variable is defined or becomes undefined in one iteration, it cannot be referenced, defined, or become undefined in another iteration.

  If the variable becomes pointer assigned, allocated, deallocated, or nullified in an iteration, its dynamic type, allocation or allocations status, shape, bounds, or a deferred-type parameter cannot be inquired about in another iteration.

  A SHARED noncontiguous array cannot be used as an actual argument associated with a contiguous INTENT(INOUT) dummy argument within the construct.

You can specify LOCAL, LOCAL_INIT, REDUCE, SHARED, and DEFAULT (NONE) in the same DO CONCURRENT statement.

	You can specify more than one of the following in the same DO CONCURRENT statement: LOCAL, LOCAL_INIT, REDUCE, and SHARED.
block	Is a sequence of zero or more statements or constructs that make up the DO range.

A variable that appears in a *mask-expr*, *concurrent-step*, or *concurrent-limit* of a *concurrent-header*, cannot appear in a LOCAL *locality-spec* in the same DO CONCURRENT statement.

If a construct name is specified in a DO CONCURRENT statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO CONCURRENT statement, no name can appear in the terminal END DO statement, if one is specified.

If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive. You can branch to the END DO statement only from within the construct.

When the DO CONCURRENT construct terminates, a variable that is defined or becomes undefined during more than one iteration of the construct becomes undefined.

The DO CONCURRENT range is executed for every active combination of the *index-name* values.

Each execution of the range is an iteration. The executions can occur in any order.

Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

A branch within a DO CONCURRENT construct must not have a branch target that is outside the construct.

The following cannot appear in a DO CONCURRENT construct:

- A RETURN statement
- An image control statement
- A branch to a target outside the construct block
- A statement that may result in the deallocation of a polymorphic variable
- An input/output statement with an ADVANCE= specifier
- A reference to a nonpure procedure
- A reference to module IEEE_EXCEPTIONS procedure IEEE_GET_FLAG, IEEE_SET_HALTING_MODE, IEEE GET_STATUS, IEEE_SET_MODES, IEEE_SET_STATUS, or IEEE_GET_HALTING_MODE
- A reference to module IEEE_ARITHMETIC procedure IEEE_SET_ROUNDING_MODE or IEE_SET_UNDERFLOW_MODE

An EXIT statement must not appear within a DO CONCURRENT construct if it belongs to that construct or an outer construct.

A variable with LOCAL or LOCAL_INIT locality is a construct entity with the same type, type parameters, and rank as variable with the same name in the innermost construct or scope containing the DO CONCURRENT construct. The variable outside the construct is inaccessible by that name inside the DO CONCURRENT construct.

The following are rules for *variable-name* in a *locality-spec*:

- A *variable-name* must be the name of a variable that is accessible in the innermost construct containing the DO CONCURRENT statement. *variable-name* can appear at most once in any *locality-spec* of a DO CONCURRENT statement. It cannot be the same as *index-name* of the same DO CONCURRENT statement.
- A *variable-name* in a LOCAL or LOCAL_INIT *locality-spec* cannot have the OPTIONAL, ALLOCATABLE, or INTENT(IN) attribute, it cannot be a non-pointer polymorphic dummy argument, a coarray or an assumed-size array, or be of a type that is finalizable.
- *variable-name* is not permitted in a LOCAL, LOCAL_INIT, or REDUCE *locality-spec* if it is not permitted in a variable-definition context.

At the beginning of each iteration, a variable with LOCAL locality that is a pointer has pointer association status of undefined; otherwise, it is undefined except for any subobjects that are default initialized. A variable with LOCAL_INIT locality has the definition status and pointer association status of the variable outside the construct. The variable outside the construct cannot be an undefined nonallocatable nonpointer variable, or an undefined pointer.

A variable with the REDUCE locality is a construct entity with the same type, type parameters, rank, and bounds as the variable with the same name in the innermost construct or scope containing the DO CONCURENT construct (outside variable). Within the construct, the outside variable is inaccessible by that name. The following are additional rules:

- If the outside variable has the ALLOCATABLE attribute, it must be allocated; if it has the POINTER attribute, it must be associated.
- If the outside variable has the CONTIGUOUS attribute, the construct entity has the CONTIGUOUS attribute.
- The construct entity does not have the ALLOCATABLE, BIND, INTENT, POINTER, PROTECTED, SAVE, TARGET or VALUE attribute, even if the outside variable does. The construct entity is initialized with the value of the reduction-oper as specified in the following table prior to beginning execution of the iterations:

The *reduction-oper*	Initial Value of Construct Entity
+	0
*	1
.AND.	.TRUE.
.EQV.	.TRUE.
.NEQV.	.FALSE.
.OR.	.FALSE.
IAND	All bits set
IEOR	0
IOR	0
MAX	Largest representable value for type and kind
MIN	Smallest representable value for type and kind

In the block of a DO CONCURRENT construct, variables with REDUCE locality can only appear in the designator of a variable, as the object name, or as the leftmost part name of an array element or array section in an intrinsic assignment statement that takes one of the following forms:

```
variable = variable binary-reduction-operator expr
variable = expr binary-reduction-operator variable
variable = function-reduction-operator ([expr ,]... variable [, expr ] ...)
```

Each occurrence of `variable` in the statement must have the same form.

When the DO CONCURRENT construct completes, the outside variable of a variable with REDUCE locality is updated by combining the outside value with the values of the associated construct entities upon completion of the construct using reduction-operator. This combination can occur in any order.

A pointer that becomes associated with a LOCAL or LOCAL_INIT TARGET variable becomes undefined at the end of the iteration. If a LOCAL or LOCAL_INIT variable appears in an input/output statement, the input/output operation must complete before the iteration completes.

A construct or statement entity with the SAVE attribute and with unspecified locality in a DO CONCURRENT construct has SHARED locality. If it does not have the SAVE attribute, it is a different entity in each iteration of the construct.

The construct entity does not have the BIND, SAVE, VALUE, PROTECTED, or INTENT attribute, even if the variable with the same name outside the construct has the attribute. The construct entity does have the VOLATILE, CONTIGUOUS, POINTER, TARGET or ASYNCHRONOUS attribute if the variable outside the construct with the same name has the attribute. If it is a non-pointer, it has the same bounds as the variable outside the construct.

The following are rules for variables with unspecified locality in DO CONCURRENT constructs:

- A variable that is referenced in an iteration must be previously defined during that iteration, or it must not be defined or become undefined during any other iteration.

  A variable that is defined or becomes undefined by more than one iteration becomes undefined when the loop terminates.
- An allocatable object that is allocated in more than one iteration must be subsequently deallocated during the same iteration in which it was allocated.

  An object that is allocated or deallocated in only one iteration must not be referenced, allocated, deallocated, defined, or become undefined in a different iteration.
- A pointer that is referenced in an iteration must have been pointer associated previously during that iteration, or it must not have its pointer association changed during any iteration.

  A pointer that has its pointer association changed in more than one iteration has an association status of undefined when the construct terminates.
- An input/output statement must not write data to a file record or position in one iteration and read from the same record or position in a different iteration.
- Records written by output statements in the range of the loop to a sequential-access file appear in the file in an indeterminate order.

The restrictions on referencing variables defined in an iteration of a DO CONCURRENT construct also apply to any procedure invoked within the loop. These restrictions ensure no interdependencies occur that might affect code optimizations.

NOTE
If compiler option `[q or Q]openmp` or option `[Q]parallel` is specified, the compiler will attempt to parallelize the construct.

NOTE
If ifx compiler option `-fopenmp-target-do-concurrent` (Linux*)
or `/Qopenmp-target-do-concurrent` (Windows*) is specified, the compiler will attempt to convert the construct into an OpenMP TARGET offload region. An I/O statement in the construct will inhibit conversion to a TARGET region; it can still be parallelized.

See the DO statement for the semantics of labeled and block forms of DO loops.

The labeled form of a DO CONCURRENT loop is an obsolescent feature in the Fortran Standard.

Examples

The following example shows a DO CONCURRENT construct with a *mask-expr* and locality specified for variables:

```
INTEGER,DIMENSION(N) :: J, K
INTEGER              :: I, M
M = 10
I = 15
DO CONCURRENT (I = 1:N, J(I)> 0)LOCAL (M) SHARED (J, K)
   M =  MOD (K(I), J(I))
   K(I) = K(I) - M
END DO
PRINT *, I, M             ! Prints 15 10
```

The following example shows a DO CONCURRENT construct that has a variable with REDUCE locality. The variable has a value of 100 prior to the DO CONCURRENT construct. The values of the array are added to the variable in a sum reduction of the array:

```
INTEGER,DIMENSION(10) :: ARRAY
INTEGER               :: I, SUM_PLUS_100 = 100

ARRAY = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
DO CONCURRENT (I = 1:10) REDUCE (+ : SUM_PLUS_100)
   SUM_PLUS_100 = SUM_PLUS_100 + ARRAY(I)
END DO
PRINT *, SUM_PLUS_100   ! Prints 155
```

DO SIMD

OpenMP* Fortran Compiler Directive: *Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.*

Syntax

```
!$OMP DO SIMD [clause[[,] clause] ... ]
      do-loop
[!$OMP END DO SIMD[NOWAIT]]
```

clause — Can be any of the clauses accepted by the DO or SIMD directives.

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

	The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team. You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END DO SIMD directive is not specified, an END DO SIMD directive is assumed at the end of *do-loop*.

You can specify the NOWAIT clause or keyword to avoid the implied barrier at the end of a loop construct.

The DO SIMD construct converts the associated DO loop to a SIMD loop in a way that is consistent with any clauses that apply to the SIMD construct. The resulting SIMD chunks and any remaining iterations will be distributed across the implicit tasks of the parallel region in a way that is consistent with any clauses that apply to the DO construct.

This directive specifies a composite construct.

Syntax Rules for Compiler Directives
NOWAIT clause

DO WHILE

Statement: *Executes the range of a DO construct while a specified condition remains true.*

Syntax

```
[name:] DO [label[, ]] WHILE (expr)
   block
[END DO [name]]
```

name	(Optional) Is the name of the DO WHILE construct.
label	(Optional) Is a label specifying an executable statement in the same program unit.
expr	Is a scalar logical (test) expression enclosed in parentheses.
block	Is a sequence of zero or more statements or constructs that make up the DO range.

Description

If a construct name is specified in a DO WHILE statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO WHILE statement, no name can appear in the terminal END DO statement, if one is specified.

Before each execution of the DO range, the logical expression is evaluated. If it is true, the statements in the body of the loop are executed. If it is false, the DO construct terminates and control transfers to the statement following the loop.

If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive.

If no label appears in a DO WHILE statement, the DO WHILE loop must be terminated with an END DO statement. See the description of the DO statement for the semantics of labeled and block forms of DO loops.

You can transfer control out of a DO WHILE loop but not into a loop from elsewhere in the program.

Terminating a DO WHILE loop with an executable statement other than a DO WHILE or a CONTINUE statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The labeled form of a DO WHILE loop is an obsolescent feature in the Fortran Standard.

Example

The following example shows a DO WHILE statement:

```
CHARACTER*132 LINE
...
I = 1
DO WHILE (LINE(I:I) .EQ. ' ')
  I = I + 1
END DO
```

The following examples show required and optional END DO statements:

```
RequiredOptional
DO WHILE (I .GT. J)          DO 10 WHILE (I .GT. J)
  ARRAY(I,J) = 1.0             ARRAY(I,J) = 1.0
  I = I - 1                    I = I - 1
END DO                      10 END DO
```

The following shows another example:

```
CHARACTER(1) input
input = ' '
DO WHILE ((input .NE. 'n') .AND. (input .NE. 'y'))
   WRITE (*, '(A,\)') 'Enter y or n: '
   READ (*, '(A)') input
END DO
```

DOT_PRODUCT

Transformational Intrinsic Function (Generic):
Performs dot-product multiplication of numeric or logical vectors (rank-one arrays).

Syntax

`result = DOT_PRODUCT (vector_a,vector_b)`

vector_a	(Input) Must be a rank-one array of numeric (integer, real, or complex) or logical type.
vector_b	(Input) Must be a rank-one array of numeric type if *vector_a* is of numeric type, or of logical type if *vector_a* is of logical type. It must be the same size as *vector_a*.

Results

The result is a scalar whose type depends on the types of *vector_a* and *vector_b*.

If *vector_a* is of type integer or real, the result value is SUM (*vector_a** *vector_b*).

If *vector_a* is of type complex, the result value is SUM (CONJG (*vector_a*)* *vector_b*).

If *vector_a* is of type logical, the result has the value ANY (*vector_a*.AND. *vector_b*).

If either rank-one array has size zero, the result is zero if the array is of numeric type, and false if the array is of logical type.

Example

DOT_PRODUCT ((/1, 2, 3/), (/3, 4, 5/)) has the value 26, calculated as follows:

```
((1 x 3) + (2 x 4) + (3 x 5)) = 26
```

DOT_PRODUCT ((/ (1.0, 2.0), (2.0, 3.0) /), (/ (1.0, 1.0), (1.0, 4.0) /)) has the value (17.0, 4.0).

DOT_PRODUCT ((/ .TRUE., .FALSE. /), (/ .FALSE., .TRUE. /)) has the value false.

The following shows another example:

```
  I = DOT_PRODUCT((/1,2,3/), (/4,5,6/))  ! returns the value 32
```

DOUBLE COMPLEX

Statement: *Specifies the DOUBLE COMPLEX data type.*

Syntax

```
DOUBLE COMPLEX
```

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(KIND=8) or DOUBLE COMPLEX constants. (For more information, see REAL and DOUBLE PRECISION.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* binary64 format.

Example

```
DOUBLE COMPLEX vector, arrays(7,29)
DOUBLE COMPLEX pi, pi2 /3.141592654,6.283185308/
```

Valid COMPLEX(8) or DOUBLE COMPLEX constants

(547.3E0_8,-1.44_8)

(1.7039E0,-1.7039D0)

(+12739D3,0.D0)

Invalid COMPLEX(8) or DOUBLE COMPLEX constants

(1.23D0,)	Second constant missing.
(1D1,2H12)	Hollerith constants not allowed.
(1,1.2)	Neither constant is DOUBLE PRECISION; this is a valid single-precision real constant.

General Rules for Complex Constants
COMPLEX Statement
Complex Data Types
DOUBLE PRECISION
REAL

DOUBLE PRECISION

Statement: *Specifies the DOUBLE PRECISION data type.*

Syntax

```
DOUBLE PRECISION
```

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE* binary64 format is used.

For more information, see General Rules for Real Constants.

Example

```
DOUBLE PRECISION varnam
DOUBLE PRECISION,PRIVATE :: zz
```

Valid REAL(8) or DOUBLE PRECISION constants

123456789D+5

123456789E+5_8

+2.7843D00

-.522D-12

2E200_8

2.3_8

3.4E7_8

Invalid REAL(8) or DOUBLE PRECISION constants

-.25D0_2	2 is not a valid kind type for reals.
+2.7182812846182	No D exponent designator is present; this is a valid single-precision constant.

123456789.D400	Too large for any double-precision format.
123456789.D-400	Too small for any double-precision format.

Real Data Types

DPROD

Elemental Intrinsic Function (Specific): *Produces a higher precision product. This is a specific function that has no generic function associated with it.*

Syntax

```
result = DPROD (x, y)
```

x	(Input) Must be of type REAL(4) or REAL(8).
y	(Input) Must have the same type and kind parameters as *x*.

Results

If *x* and *y* are of type REAL(4), the result type is double-precision real (REAL(8) or REAL*8). If *x* and *y* are of type REAL(8), the result type is REAL(16). The result value is equal to *x** *y*.

The setting of compiler options specifying real size can affect this function.

Example

DPROD (2.0, -4.0) has the value -8.00D0.

DPROD (5.0D0, 3.0D0) has the value 15.00Q0.

The following shows another example:

```
REAL(4) e
REAL(8) d
e = 123456.7
d = 123456.7D0
! DPROD (e,e) returns 15241557546.4944

! DPROD (d,d) returns 15241556774.8899992813874268904328
```

DRAND, DRANDM

Portability Functions: *Return double-precision random numbers in the range 0.0 to 1.0, not including the end points.*

Module

USE IFPORT

Syntax

```
result = DRAND (iflag)
```

```
result = DRANDM (iflag)
```

iflag (Input) INTEGER(4). Controls the way the random number is selected.

Results

The result type is REAL(8). DRAND and DRANDM return random numbers in the range 0.0 to 1.0, not including the end points.

Value of *iflag*	Selection process
1	The generator is restarted and the first random value is selected.
0	The next random number in the sequence is selected.
Otherwise	The generator is reseeded using *iflag*, then restarted, and the first random value is selected.

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.

The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

Example

```
USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
CALL print_rand
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,':',num
  END SUBROUTINE
END
```

See Also

RANDOM_INIT

RANDOM_NUMBER
RANDOM_SEED

DRANSET

Portability Subroutine: *Sets the seed for the random number generator.*

Module

USE IFPORT

Syntax

CALL DRANSET (*seed*)

seed	(Input) REAL(8). The reset value for the seed.

See Also
RANGET

DREAL
Elemental Intrinsic Function (Specific): *Converts the real part of a double complex argument to double-precision type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.*

Syntax
```
result = DREAL (a)
```

a	(Input) Must be of type double complex (COMPLEX(8) or COMPLEX*16).

Results
The result type is double precision real (REAL(8) or REAL*8).

Example
DREAL ((2.0d0, 3.0d0)) has the value 2.0d0.

See Also
REAL

DSHIFTL
Elemental Intrinsic Function (Specific): *Selects the left 64 bits after shifting a 128-bit integer value to the left. This function cannot be passed as an actual argument.*

Syntax
```
result = DSHIFTL (i,j,shift)
```

i	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant. If both *i* and *j* are of type integer, they must have the same kind type parameter. *i* and *j* must not both be binary, octal, or hexadecimal literal constants.
shift	(Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

Results
The result type is integer. The result value is the 64-bit value starting at bit 128 - *shift* of the 128-bit concatenation of the values of *i* and *j*.

If either *i* or *j* is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The rightmost *shift* bits of the result value are the same as the leftmost bits of *i*, and the remaining bits of the result value are the same as the rightmost bits of *j*. This is equal to IOR (SHIFTL (I, SHIFT), SHIFTR (J, BIT SIZE (J) - SHIFT)).

Example

Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /
PRINT *, DSHIFTL (ILEFT, IRIGHT, 16_8)  ! prints 1306643199093243919
```

Model for Bit Data

DSHIFTR

Elemental Intrinsic Function (Specific): *Selects the left 64 bits after shifting a 128-bit integer value to the right. This function cannot be passed as an actual argument.*

Syntax

`result = DSHIFTR (i,j,shift)`

i	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
shift	(Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

Results

The result type is integer. The result value is the 64-bit value starting at bit 64 + *shift* of the 128-bit concatenation of the values of *i* and *j*.

If either *i* or *j* is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The leftmost *shift* bits of the result value are the same as the rightmost bits of *i*, and the remaining bits of the result value are the same as the leftmost bits of *j*. This is equal to IOR (SHIFTL (I, BIT SIZE (I) - SHIFT), SHIFTR (J, SHIFT)).

Example

Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /
PRINT *, DSHIFTR (ILEFT, IRIGHT, 16_8)  ! prints 1306606910610341887
```

Model for Bit Data

DTIME

Portability Function: *Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.*

Module

USE IFPORT

Syntax

`result = DTIME (tarray)`

tarray	(Output) REAL(4). A rank one array with two elements: • *tarray*(1) - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. • *tarray*(2) - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

Results

The result type is REAL(4). The result is the total CPU time, which is the sum of *tarray*(1) and *tarray*(2). If an error occurs, -1 is returned.

Example

```
USE IFPORT
REAL(4) I, TA(2)
I = DTIME(TA)
write(*,*) 'Program has been running for', I, 'seconds.'
write(*,*) ' This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'
```

E to F

This section describes language features that start with E or F.

E to F

ELEMENTAL

Keyword: *Asserts that a user-defined procedure is defined in scalar arguments that can be called with array arguments. Unless declared IMPURE, an ELEMENTAL procedure is by default PURE.*

Description

An elemental procedure is an elemental intrinsic procedure, an intrinsic module procedure that is specified to be elemental, a user-defined procedure that is specified to be elemental, or a type-bound procedure that is bound to an elemental procedure. A procedure pointer or a dummy procedure cannot be specified to be elemental.

To specify an elemental procedure, use this keyword in a FUNCTION or SUBROUTINE statement.

An explicit interface must be visible to the caller of an ELEMENTAL procedure.

An elemental procedure can be passed an array, which is acted upon one element at a time.

For functions, the result must be scalar; it cannot have the POINTER or ALLOCATABLE attribute.

Dummy arguments in ELEMENTAL procedures may appear in specification expressions in the procedure.

Dummy arguments have the following restrictions:

- They must be scalar.
- They cannot have the POINTER or ALLOCATABLE attribute.
- They cannot be an alternate return specifier (*).
- They cannot be dummy procedures.

If the actual arguments are all scalar, the result is scalar. If the actual arguments are array valued, the values of the elements (if any) of the result are the same as if the function or subroutine had been applied separately, in any order, to corresponding elements of each array actual argument.

Elemental procedures are pure procedures by default and all rules that apply to pure procedures also apply to elemental procedures, unless you specify that the elemental procedure is IMPURE. In that case, the rules for pure procedures do not apply.

Example

Consider the following:

```
  MIN (A, 0, B)             ! A and B are arrays of shape (S, T)
```

In this case, the elemental reference to the MIN intrinsic function is an array expression whose elements have the following values:

```
  MIN (A(I,J), 0, B(I,J)), I = 1, 2, ..., S, J = 1, 2, ..., T
```

Consider the following example:

```
ELEMENTAL REAL FUNCTION F (A, B, ORDER)
REAL, INTENT (IN)       :: A, B
INTEGER, INTENT (IN)    :: ORDER
REAL                    :: TEMP (ORDER)
```

In the above, the size of TEMP depends on the specification expression that is the value of the ORDER dummy argument.

ELSE Directive

Statement: *Marks an optional branch in an IF Directive Construct.*

See Also

See IF Directive Construct.

ELSE Statement

Statement: *Marks an optional branch in an IF Construct.*

See Also

See IF Construct.

ELSEIF Directive

Statement: *Marks an optional branch in an IF Directive Construct.*

See Also

See IF Directive Construct.

ELSE IF

Statement: *Marks an optional branch in an IF Construct.*

See Also

See IF Construct.

ELSE WHERE

Statement: *Marks the beginning of an ELSE WHERE block within a WHERE construct.*

Syntax

```
[name:]WHERE (mask-expr1)
   [where-body-stmt]...
[ELSE WHERE(mask-expr2) [name]
   [where-body-stmt]...]
[ELSE WHERE[name]
   [where-body-stmt]...]
END WHERE [name]
```

name
Is the name of the WHERE construct.

mask-expr1, mask-expr2
Are logical array expressions (called mask expressions).

where-body-stmt
Is one of the following:

- An assignment statement of the form: array variable = array expression.

  The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
- A WHERE statement or construct

Description

Every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. *mask-expr1*". If ELSE WHERE specifies "*mask-expr2*", it is executed as "(.NOT. *mask-expr1*) .AND. *mask-expr2*" during the processing of the ELSE WHERE statement.

Example

```
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

The variables `temp`, `pressure`, and `raining` are all arrays.

See Also

WHERE

ENCODE

Statement: *Translates data from internal (binary) form to character form. It is comparable to using internal files in formatted sequential WRITE statements.*

Syntax

ENCODE (*c*,*f*,*b*[, IOSTAT=*i-var*] [, ERR=*label*]) [*io-list*]

c	Is a scalar integer expression. It is the number of characters to be translated to internal form.
f	Is a format identifier. An error occurs if more than one record is specified.
b	Is a scalar or array reference. If *b* is an array reference, its elements are processed in the order of subscript progression. *b* contains the characters to be translated to internal form.
i-var	Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
label	Is the label of an executable statement that receives control if an error occurs.
io-list	Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list contains the data to be translated to character form. The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the ENCODE statement can translate depends on the data type of *b*. For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

Example

Consider the following:

```
      DIMENSION K(3)
      CHARACTER*12 A,B
      DATA A/'123456789012'/
      DECODE(12,100,A) K
100   FORMAT(3I4)
      ENCODE(12,100,B) K(3), K(2), K(1)
```

The DECODE statement stores the 12 characters into array K:

```
K(1) = 1234
K(2) = 5678
K(3) = 9012
```

The ENCODE statement translates the values K(3), K(2), and K(1) to character form and stores the characters in the character variable B.:

```
B = '901256781234'
```

See Also

READ
WRITE
DECODE

END

Statement: *Marks the end of a program unit. It takes one of the following forms:*

Syntax

END [PROGRAM [*program-name*]]

END [FUNCTION [*function-name*]]

END [SUBROUTINE [*subroutine-name*]]

END [MODULE [*module-name*]]

END [SUBMODULE [*module-name*]]

END [BLOCK DATA [*block-data-name*]]

In main programs, function subprograms, and subroutine subprograms, END statements are executable and can be branch target statements. If control reaches the END statement in these program units, the following occurs:

- In a main program, execution of the END statement initiates normal termination of the image that executes it.
- In a function or subroutine subprogram, a RETURN statement is implicitly executed.

The END statement cannot be continued in a program unit, and no other statement in the program unit can have an initial line that appears to be the program unit END statement.

The END statements in a module or block data program unit are nonexecutable.

Example

```
C   An END statement must be the last statement in a program
C   unit:
    PROGRAM MyProg
    WRITE (*, '("Hello, world!")')
    END
C
C   An example of a named subroutine
C
    SUBROUTINE EXT1 (X,Y,Z)
      Real, Dimension (100,100) :: X, Y, Z
    END SUBROUTINE EXT1
```

See Also

Program Units and Procedures

Branch Statements
Program Termination

END DO

Statement: *Marks the end of a DO or DO WHILE loop.*

Syntax

```
END DO
```

Description

There must be a matching END DO statement for every DO or DO WHILE statement that does not contain a label reference.

An END DO statement can terminate only one DO or DO WHILE statement. If you name the DO or DO WHILE statement, the END DO statement can specify the same name.

Example

The following examples both produce the same output:

```
  DO ivar = 1, 10
    PRINT ivar
  END DO
  ivar = 0
do2: DO WHILE (ivar .LT. 10)
        ivar = ivar + 1
        PRINT ivar
     END DO do2
```

See Also

DO
DO WHILE
CONTINUE

ENDIF Directive

Statement: *Marks the end of an IF Directive Construct.*

See Also

See IF Directive Construct.

END IF

Statement: *Marks the end of an IF Construct.*

See Also

See IF Construct.

ENDFILE

Statement: *For sequential files, writes an end-of-file record to the file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.*

Syntax

It can have either of the following forms:

```
ENDFILE ([UNIT=] io-unit[, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

ENDFILE *io-unit*

io-unit	(Input) Is an external unit specifier.
label	Is the label of the branch target statement that receives control if an error occurs.
msg-var	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
i-var	(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

If the unit specified in the ENDFILE statement is not open, the default file is opened for unformatted output.

An end-of-file record can be written only to files with sequential organization that are accessed as formatted-sequential or unformatted-segmented sequential files. An ENDFILE performed on a direct access file always truncates the file.

End-of-file records should not be written in files that are read by programs written in a language other than Fortran.

NOTE
If you use compiler option vms and an ENDFILE is performed on a sequential unit, an actual one byte record containing a CTRL+Zis written to the file. If this option is not specified, an internal ENDFILE flag is set and the file is truncated. The option does not affect ENDFILE on relative files; such files are truncated.

If a parameter of the ENDFILE statement is an expression that calls a function, that function must not cause an I/O statement or the EOF intrinsic functionto be executed, because unpredictable results can occur.

Example

The following statement writes an end-of-file record to I/O unit 2:

```
ENDFILE 2
```

Suppose the following statement is specified:

```
ENDFILE (UNIT=9, IOSTAT=IOS, ERR=10)
```

An end-of-file record is written to the file connected to unit 9. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable `IOS`.

The following shows another example:

```
WRITE (6, *) x
ENDFILE 6
REWIND 6
READ (6, *) y
```

END FORALL

Statement: *Marks the end of a FORALL construct. The FORALL construct is an obsolescent language feature in Fortran 2018.*

See Also

See FORALL.

END INTERFACE

Statement: *Marks the end of an INTERFACE block.*

See Also

See INTERFACE.

END TYPE

Statement: *Specifies the end of a derived type TYPE statement.*

See Also

See TYPE Statement (Derived Types).

END WHERE

Statement: *Marks the end of a WHERE construct.*

Example

```
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

Note that the variables `temp`, `pressure`, and `raining` are all arrays.

See Also

See WHERE.

ENTRY

Statement: *Provides one or more entry points within a subprogram. It is not executable. The ENTRY statement is an obsolescent feature in the Fortran standard.*

Syntax

ENTRY *name*[([*d-arg*[,*d-arg*]...]) [*suffix*]]

name	Is the name of an entry point. If RESULT is specified, this entry name must not appear in any specification statement in the scoping unit of the function subprogram.
d-arg	(Optional) Is a dummy argument. The dummy argument can be an alternate return indicator (*) only if the ENTRY statement is within a subroutine subprogram.
suffix	(Optional) Is one of the following: RESULT (*r-name*) [*language-binding-spec*]

	or *language-binding-spec* [RESULT (*r-name*)]
r-name	(Optional) Is the name of a function result. This name must not be the same as the name of the entry point, or the name of any other function or function result. This parameter can only be specified for function subprograms.
language-binding-spec	Is the following: BIND (C [, NAME = *scalar-default-char-constant-expr*]) If NAME appears, *scalar-default-char-constant-expr* specifies the external name of the procedure defined by this ENTRY statement.

Description

ENTRY statements can only appear in an external procedure or a module that is not the definition of a separate module procedure. An ENTRY statement cannot appear in an internal procedure. A subprogram can contain zero or more ENTRY statements.

An ENTRY statement must not appear in an executable construct.

When the ENTRY statement appears in a subroutine subprogram, it is referenced by a CALL statement. When the ENTRY statement appears in a function subprogram, it is referenced by a function reference.

An entry name within a function subprogram can appear in a type declaration statement, unless RESULT is specified. If RESULT is specified, *r-name* can appear in a type declaration statement, and the entry name cannot appear in a type declaration statement or other specification statements.

Within the subprogram containing the ENTRY statement, the entry name must not appear as a dummy argument in the FUNCTION or SUBROUTINE statement, and it must not appear in an EXTERNAL or INTRINSIC statement. For example, neither of the following are valid:

```
(1)  SUBROUTINE SUB(E)
     ENTRY E
     ...

(2)  SUBROUTINE SUB
     EXTERNAL E
     ENTRY E
     ...
```

The procedure defined by an ENTRY statement can reference itself if the function or subroutine was defined as RECURSIVE.

Dummy arguments can be used in ENTRY statements even if they differ in order, number, type and kind parameters, and name from the dummy arguments used in the FUNCTION, SUBROUTINE, and other ENTRY statements in the same subprogram. However, each reference to a function, subroutine, or entry must use an actual argument list that agrees in order, number, and type with the dummy argument list in the corresponding FUNCTION, SUBROUTINE, or ENTRY statement.

Dummy arguments can be referred to only in executable statements that follow the first SUBROUTINE, FUNCTION, or ENTRY statement in which the dummy argument is specified. If a dummy argument is not currently associated with an actual argument, the dummy argument is undefined and cannot be referenced. Arguments do not retain their association from one reference of a subprogram to another.

Example

```
C  This fragment writes a message indicating
C  whether num is positive or negative
   IF (num .GE. 0) THEN
     CALL Sign
   ELSE
     CALL Negative
   END IF
   ...
   END
SUBROUTINE Sign
   WRITE (*, *) 'It''s positive.'
   RETURN
   ENTRY Negative
   WRITE (*, *) 'It''s negative.'
   RETURN
END SUBROUTINE
```

EOF

Inquiry Intrinsic Function (Generic): *Checks whether a file is at or beyond the end-of-file record.*

Syntax

`result = EOF (unit)`

unit	(Input) Must be of type integer. It represents a unit specifier corresponding to an open file. It cannot be zero unless you have reconnected unit zero to a unit other than the screen or keyboard.

Results

The result type is default logical. The value of the result is .TRUE. if the file connected to *unit* is at or beyond the end-of-file record; otherwise, .FALSE..

Example

```
!  Creates a file of random numbers, reads them back
       REAL x, total
       INTEGER count
       OPEN (1, FILE = 'TEST.DAT')
       DO I = 1, 20
         CALL RANDOM_NUMBER(x)
         WRITE (1, '(F6.3)') x * 100.0
       END DO
       CLOSE(1)
       OPEN (1, FILE = 'TEST.DAT')
       count = 0
       total = 0.0
       DO WHILE (.NOT. EOF(1))
         count = count + 1
```

```
        READ (1, *) value
        total = total + value
      END DO
100   IF ( count .GT. 0) THEN
        WRITE (*,*) 'Average is: ', total / count
      ELSE
        WRITE (*,*) 'Input file is empty '
      END IF
       STOP
      END
```

See Also

BACKSPACE

REWIND

EOSHIFT

Transformational Intrinsic Function (Generic):
Performs an end-off shift on a rank-one array, or performs end-off shifts on all the complete rank-one sections along a given dimension of an array of rank two or greater. Elements are shifted off at one end of a section and copies of a boundary value are filled in at the other end. Different sections can have different boundary values and can be shifted by different amounts and in different directions.

Syntax

`result = EOSHIFT (array,shift [,boundary][,dim])`

array

(Input) Must be an array (of any data type).

shift

(Input) Must be a scalar integer or an array with a rank that is one less than *array*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *array*.

boundary

(Input; optional) Must have the same type and kind parameters as *array*. It must be a scalar or an array with a rank that is one less than *array*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n). The *boundary* specifies a value to replace spaces left by the shifting procedure.

If *boundary* is not specified, it is assumed to have the following default values (depending on the data type of *array*):

array **Type**	*boundary* **Value**
Integer	0
Real	0.0
Complex	(0.0, 0.0)
Logical	false
Character(*len*)	*len* blanks

dim	(Input; optional) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*. If *dim* is omitted, it is assumed to be 1.

Results

The result is an array with the same type and kind parameters, and shape as *array*.

If *array* has rank one, the same shift is applied to each element. If an element is shifted off one end of the array, the *boundary* value is placed at the other end the array.

If *array* has rank greater than one, each section (s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) of the result is shifted as follows:

- By the value of *shift*, if *shift* is scalar
- According to the corresponding value in *shift*(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n), if *shift* is an array

If an element is shifted off one end of a section, the *boundary* value is placed at the other end of the section.

The value of *shift* determines the amount and direction of the end- off shift. A positive *shift* value causes a shift to the left (in rows) or up (in columns). A negative *shift* value causes a shift to the right (in rows) or down (in columns).

Example

V is the integer array (1, 2, 3, 4, 5, 6).

EOSHIFT (V, SHIFT=2) shifts the elements in V to the *left* by 2 positions, producing the value (3, 4, 5, 6, 0, 0). 1 and 2 are shifted off the beginning and two elements with the default BOUNDARY value are placed at the end.

EOSHIFT (V, SHIFT= -3, BOUNDARY= 99) shifts the elements in V to the *right* by 3 positions, producing the value (99, 99, 99, 1, 2, 3). 4, 5, and 6 are shifted off the end and three elements with BOUNDARY value 99 are placed at the beginning.

M is the CHARACTER(LEN=1) array

```
[ 1  2  3 ]
[ 4  5  6 ]
[ 7  8  9 ].
```

EOSHIFT (M, SHIFT = 1, BOUNDARY = '*', DIM = 2) produces the result

```
[ 2  3  * ]
[ 5  6  * ]
[ 8  9  * ].
```

Each element in rows 1, 2, and 3 is shifted to the *left* by 1 position. This causes the first element in each row to be shifted off the beginning, and the BOUNDARY value to be placed at the end.

EOSHIFT (M, SHIFT = -1, DIM = 1) produces the result

```
[ ^  ^  ^ ]
[ 1  2  3 ]
[ 4  5  6 ].
```

Each element in columns 1, 2, and 3 is shifted *down* by 1 position. This causes the last element in each column to be shifted off the end and the BOUNDARY value (the default character boundary value <space>, represented by "^") to be placed at the beginning.

EOSHIFT (M, SHIFT = (/1, -1, 0/), BOUNDARY = (/ '*', '?', '/' /), DIM = 2) produces the result

```
  [ 2  3  * ]
  [ ?  4  5 ]
  [ 7  8  9 ].
```

Each element in row 1 is shifted to the *left* by 1 position, causing the first element to be shifted off the beginning and the BOUNDARY value * to be placed at the end. Each element in row 2 is shifted to the *right* by 1 position, causing the last element to be shifted off the end and the BOUNDARY value ? to be placed at the beginning. No element in row 3 is shifted at all, so the specified BOUNDARY value is not used.

The following shows another example:

```
INTEGER shift(3)
CHARACTER(1) array(3, 3), AR1(3, 3)
array = RESHAPE ((/'A', 'D', 'G', 'B', 'E', 'H', &
                   'C', 'F', 'I'/), (/3,3/))
!        array is A B C
!                 D E F
!                 G H I
shift = (/-1, 1, 0/)
AR1 = EOSHIFT (array, shift, BOUNDARY = (/'*','?','#'/), DIM= 2)
! returns         * A B
!                 E F ?
!                 G H I
```

EPSILON

Inquiry Intrinsic Function (Generic): *Returns a positive model number that is almost negligible compared to unity in the model representing real numbers.*

Syntax

```
result = EPSILON (x)
```

x (Input) Must be of type real; it can be scalar or array valued.

Results

The result is a scalar of the same type and kind parameters as *x*. The result has the value b^{1-p}. Parameters *b* and *p* are defined in Model for Real Data.

EPSILON makes it easy to select a *delta* for algorithms (such as root locators) that search until the calculation is within *delta* of an estimate. If *delta* is too small (smaller than the decimal resolution of the data type), the algorithm might never halt. By scaling the value returned by EPSILON to the estimate, you obtain a *delta* that ensures search termination.

Example

If *x* is of type REAL(4), EPSILON (X) has the value 2^{-23}.

EQUIVALENCE

Statement: *Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area. EQUIVALENCE is an obsolescent language feature in Standard Fortran.*

Syntax

`EQUIVALENCE (equiv-list) [,(equiv-list)]...`

equiv-list

Is a list of two or more variable names, array elements, or substrings, separated by commas (also called an equivalence set). If an object of derived type is specified, it must be a sequence type. Objects cannot have the TARGET attribute.

Each expression in a subscript or a substring reference must be an integer constant expression. A substring must not have a length of zero.

Description

The following objects cannot be specified in EQUIVALENCE statements:

- A dummy argument
- An allocatable variable
- An automatic object
- A pointer
- An object of nonsequence derived type
- A derived-type object that has an allocatable or pointer component at any level
- A component of a derived-type object
- A function, entry, or result name
- A named constant
- A structure component
- A subobject of any of the above objects
- A coarray
- An object with either the DLLIMPORT or DLLEXPORT attribute
- A variable with the BIND attribute
- A variable in a common block that has the BIND attribute

The EQUIVALENCE statement causes all of the entities in one parenthesized list to be allocated storage beginning at the same storage location.

If an equivalence object has the PROTECTED attribute, all of the objects in the equivalence set must have the PROTECTED attribute.

Association of objects depends on their types, as follows:

Type of Object	Type of Associated Object
Intrinsic numeric [1]or numeric sequence	Can be of any of these types
Default character or character sequence	Can be of either of these types [2]
Any other intrinsic type	Must have the same type and kind parameters
Any other sequence type	Must have the same type

Type of Object	Type of Associated Object

[1]Default integer, default real, double precision real, default complex, double complex, or default logical.

[2]The lengths do not have to be equal.

So, objects can be associated if they are of different numeric type. For example, the following is valid:

```
INTEGER A(20)
REAL Y(20)
EQUIVALENCE(A, Y)
```

Objects of default character do not need to have the same length. The following example associates character variable D with the last 4 (of the 6) characters of character array F:

```
CHARACTER(LEN=4) D
CHARACTER(LEN=3) F(2)
EQUIVALENCE(D, F(1)(3:))
```

Entities having different data types can be associated because multiple components of one data type can share storage with a single component of a higher-ranked data type. For example, if you make an integer variable equivalent to a complex variable, the integer variable shares storage with the real part of the complex variable.

The same storage unit cannot occur more than once in a storage sequence, and consecutive storage units cannot be specified in a way that would make them nonconsecutive.

Intel® Fortran lets you associate character and noncharacter entities, for example:

```
CHARACTER*1 char1(10)
REAL reala, realb
EQUIVALENCE (reala, char1(1))
EQUIVALENCE (realb, char1(2))
```

EQUIVALENCE statements require only the first subscript of a multidimensional array (unless the STRICT compiler directive is in effect). For example, the array declaration var(3,3), var(4) could appear in an EQUIVALENCE statement. The reference is to the fourth element of the array (var(1,2)), not to the beginning of the fourth row or column.

If you use the STRICT directive, the following rules apply to the kinds of variables and arrays that you can associate:

- If an EQUIVALENCE object is default integer, default real, double-precision real, default complex, default logical, or a sequenced derived type of all numeric or logical components, all objects in the EQUIVALENCE statement must be one of these types, though it is not necessary that they be the same type.
- If an EQUIVALENCE object is default character or a sequenced derived type of all character components, all objects in the EQUIVALENCE statement must be one of these types. The lengths do not need to be the same.
- If an EQUIVALENCE object is a sequenced derived type that is not purely numeric or purely character, all objects in the EQUIVALENCE statement must be the same derived type.
- If an EQUIVALENCE object is an intrinsic type other than the default (for example, INTEGER(1)), all objects in the EQUIVALENCE statement must be the same type and kind.

Example

The following EQUIVALENCE statement is invalid because it specifies the same storage unit for X(1) and X(2):

```
REAL, DIMENSION(2) :: X
REAL :: Y
EQUIVALENCE(X(1), Y), (X(2), Y)
```

The following EQUIVALENCE statement is invalid because A(1) and A(2) will not be consecutive:

```
REAL A(2)
DOUBLE PRECISION D(2)
EQUIVALENCE(A(1), D(1)), (A(2), D(2))
```

In the following example, the EQUIVALENCE statement causes the four elements of the integer array IARR to share the same storage as that of the double-precision variable DVAR:

```
DOUBLE PRECISION DVAR
INTEGER(KIND=2) IARR(4)
EQUIVALENCE(DVAR, IARR(1))
```

In the following example, the EQUIVALENCE statement causes the first character of the character variables KEY and STAR to share the same storage location. The character variable STAR is equivalent to the substring KEY(1:10).

```
CHARACTER KEY*16, STAR*10
EQUIVALENCE(KEY, STAR)
```

The following shows another example:

```
CHARACTER name, first, middle, last
DIMENSION name(60), first(20), middle(20), last(20)
EQUIVALENCE (name(1), first(1)), (name(21), middle(1))
EQUIVALENCE (name(41), last(1))
```

Consider the following:

```
CHARACTER (LEN = 4) :: a, b
CHARACTER (LEN = 3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))
```

This causes the following alignment:

```
  1          2          3          4          5          6          7
a(1:1)     a(2:2)     a(3:3)     a(4:4)
                                 b(1:1)     b(2:2)     b(3:3)     b(4:4)
c(1)(1:1)  c(1)(2:2)  c(1)(3:3)  c(2)(1:1)  c(2)(2:2)  c(2)(3:3)
```

Note that the fourth element of a, the first element of b, and the first element of c(2) share the same storage unit.

ERF

Elemental Intrinsic Function (Generic): *Returns the error function of an argument.*

Syntax

```
result = ERF (x)
```

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*. The result is in the range -1 to 1.

ERF returns the error function of *x* defined as follows:

$$\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}dt$$

Specific Name	Argument Type	Result Type
ERF	REAL(4)	REAL(4)
DERF	REAL(8)	REAL(8)
QERF	REAL(16)	REAL(16)

Example

ERF (1.0) has the value 0.842700794.

See Also

ERFC

ERFC

Elemental Intrinsic Function (Generic): *Returns the complementary error function of an argument.*

Syntax

```
result = ERFC (x)
```

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*. The result is in the range 0 to 2.

ERFC returns 1 - ERF(x) and is defined as follows:

$$\frac{2}{\sqrt{\pi}}\int_x^\infty e^{-t^2}dt$$

ERFC is provided because of the extreme loss of relative accuracy if ERF(x) is called for large *x* and the result is subtracted from 1.

Specific Name	Argument Type	Result Type
ERFC	REAL(4)	REAL(4)
DERFC	REAL(8)	REAL(8)
QERFC	REAL(16)	REAL(16)

Example

ERFC (1.0) has the value 0.1572992057.

ERF

ERFC_SCALED

Elemental Intrinsic Function (Generic): *Returns the scaled complementary error function of an argument.*

Syntax

```
result = ERFC_SCALED (x)
```

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the exponentially-scaled complementary error function of

$$\exp\left(X^2\right)\frac{2}{\sqrt{\pi}}\int_x^\infty \exp\left(-t^2\right)dt$$

NOTE

The complementary error function is asymptotic to $\exp\left(-X^2\right)/\left(X\sqrt{\pi}\right)$. As such it underflows for $X >\approx 9$ when using IEEE single precision arithmetic. The exponentially-scaled complementary error function is asymptotic to $1/\left(X\sqrt{\pi}\right)$. As such it does not underflow until $X > HUGE(X)/\sqrt{\pi}$.

Example

ERFC_SCALED (20.0) has the approximate value 0.02817434874.

ERFC

ERROR Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Causes the compiler or runtime system to process an error condition. This feature is only available for ifx.*

Syntax

```
!$OMP ERROR [clause[[,] clause]... ]
```

clause Is one or more of the following:

- AT (*action-time*)

  Determines when an implementation processes an error condition.

  action-time is COMPILATION or EXECUTION.

If *action-time* is COMPILATION and the directive appears in the specification part of a program unit, the error action occurs during compilation. If the directive appears in the executable part of the program unit that is not reachable at runtime, the error action may or may not occur.

If *action-time* is EXECUTION, the error action occurs when a thread encounters the directive. An ERROR direction that specifies AT (EXECUTION) is considered an executable directive.

If an AT clause is not specified in the ERROR directive, it is as if AT (COMPILATION) was specified.

- MESSAGE (*scalar-default-char-expression*)

  Specifies a message string to be included in the implementation defined message issued when the error action occurs.

  If *action-time* is COMPILATION, *scalar-default-char-expression* must be a constant.
- SEVERITY (*level*)

  Indicates the severity level of the error.

  level is WARNING or FATAL.

  If *level* is WARNING, a message containing *scalar-default-char-expression* is displayed and processing (compilation of execution) continues.

  If *level* is FATAL, a message containing *scalar-default-char-expression* is displayed and program termination is initiated.

  If a SEVERITY clause is not specified in the ERROR directive, it is as if SEVERITY (FATAL) was specified.

The ERROR directive is a utility directive that causes either the compiler or the runtime system to flag an error condition producing an implementation defined error message.

The directive is pure only if COMPILATION is specified for the AT clause, or the AT clause does not appear. Pure directives can appear in Fortran PURE procedures.

Each clause can appear at most once in the ERROR directive.

Syntax Rules for Compiler Directives

ERRSNS

Intrinsic Subroutine (Generic): *Returns information about the most recently detected I/O system error condition. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL ERRSNS ([io_err] [,sys_err] [,stat] [,unit] [,cond])
```

io_err (Output; Optional) Is an integer variable or array element that stores the most recent Runtime Library error number that occurred during program execution. For a listing of error numbers, see Error Handling.

	A zero indicates no error has occurred since the last call to ERRSNS or since the start of program execution.
sys_err	(Output; Optional) Is an integer variable or array element that stores the most recent system error number associated with *io_err*. This code is one of the following: • **Linux** It is an `errno` value. (See `errno(2)`.) • **Windows** It is the value returned by GETLASTERROR( ) at the time of the error.
stat	(Output; Optional) Is an integer variable or array element that stores a status value that occurred during program execution. This value is always set to zero.
unit	(Output; Optional) Is an integer variable or array element that stores the logical unit number, if the last error was an I/O error.
cond	(Output; Optional) Is an integer variable or array element that stores the actual processor value. This value is always set to zero.

If you specify INTEGER(2) arguments, only the low-order 16 bits of information are returned or adjacent data can be overwritten. Because of this, it is best to use INTEGER(4) arguments.

The saved error information is set to zero after each call to ERRSNS.

Example

Any of the arguments can be omitted. For example, the following is valid:

```
CALL ERRSNS (SYS_ERR=I1, STAT=I2, UNIT=I4)
```

ESTABLISHQQ

Portability Function: *Lets you specify a function to handle errors detected by the Runtime Library (RTL). It lets you take appropriate steps in addition to the RTL's error-handling behavior, or it lets you replace that behavior.*

Module

USE IFESTABLISH

Syntax

`result = ESTABLISHQQ (`*handler_routine*`,`*context*`,`*prev_handler*`,`*prev_context*`)`

handler_routine	(Input) Is of type "procedure(establishqq_handler)", which is defined in module IFESTABLISH. This is the function that will handle errors detected by the RTL.
context	(Input) INTEGER(INT_PTR_KIND()). This is the way you pass information to the handler function for use when it is called. It can be data or a pointer to a block of data.

prev_handler	(Optional; output) Is of type "procedure(establishqq_handler), pointer, intent(out), optional", which is defined in module IFESTABLISH. This is the previous handler function, if any.
prev_context	(Optional; output) INTEGER(INT_PTR_KIND()). This is the context specified for the previous handler function, if any; otherwise, zero.

Results

The result type for ESTABLISHQQ is LOGICAL(4). It indicates whether the handler was successfully established. .TRUE. means it was established successfully; .FALSE. means it was not.

The handler function is called when an error occurs. The result for the handler is set by your code in the handler. .TRUE. means that the error has been handled and the application should not issue an error message. .FALSE. means that the application should issue an error message and continue as if there had never been a handler.

After you use ESTABLISHQQ to specify an error handler function and an error occurs, the handler function is called with the following input arguments. They are set up by the RTL when it calls the handler function:

Handler Function Syntax:

result = Handler_Function (*error_code*, *continuable*, *message_string*, *context*)

Handler_Function is a function you supply that has a compatible interface. It must use the Intel® Fortran compiler defaults for calling mechanism and argument passing. When the Intel Fortran Runtime Library detects an error, it first calls your handler function with the following arguments:

error_code	(Input) INTEGER(4). This is the number of the error that occurred and it is the value that will be set in an IOSTAT= or STAT= specifier variable. A list of runtime error codes can be found at List of Runtime Error Messages.
continuable	(Input) LOGICAL(4). If execution can be continued after handling this error, this argument is passed the value .TRUE., otherwise, it is passed the value .FALSE.. Do not compare this value using arithmetic equality operators; use logical data type tests or .EQV.. If an error is not continuable, the program exits after processing the error.
message_string	(Input) CHARACTER(*). This is the text of the error message as it would otherwise be displayed to the user.
context	(Input) INTEGER(INT_PTR_KIND()). This is the value passed for the context argument to ESTABLISHQQ. Your handler function can use this for any purpose.

The function result of the handler function is type LOGICAL(4). The handler function should return .TRUE. if it successfully handled the error; otherwise, .FALSE..

If the handler function returns .TRUE. and the error is continuable, execution of the program continues. If the handler function returns .FALSE., normal error processing is performed, such as message output to the user and possible program termination.

The handler function can be written in any language, but it must follow the Intel Fortran conventions. Note that for argument *message_string*, an address-sized length is passed by value after argument *context*.

If you want to handle errors using a C/C++ handler, use the ISO_C_BINDINGS module features to call the C/C++ routine.

Example

```
! Compile with "-fpe0 -check bounds".
!
program example
use ifestablish
implicit none

     procedure(establishqq_handler), pointer :: old_handler_1
     procedure(establishqq_handler), pointer :: old_handler_2

ETIME

Portability Function: *On single processor systems, returns the elapsed CPU time, in seconds, of the process that calls it. On multi-core or multi-processor systems, returns the elapsed wall-clock time, in seconds.*

Module

USE IFPORT

Syntax

`result = ETIME (array)`

array

(Output) REAL(4). Must be a rank one array with two elements:

- *array(1)* – Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. On single processors, ETIME returns the elapsed CPU time, in seconds, of the process that calls it. On multiple processors, ETIME returns the elapsed wall-clock time, in seconds.
- *array(2)* – Elapsed system time, which is time spent executing privileged code (code in the Windows Executive) on single processors; on multiple processors, this value is zero.

Results

The result type is REAL(4). The result is the total CPU time, which is the sum of *array(1)* and *array(2)*.

Example

```
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
write(*,*) 'Program has used', I, 'seconds of CPU time.'
write(*,*) '  This includes', TA(1), 'seconds of user time and',  &
& TA(2), 'seconds of system time.'
```

DATE_AND_TIME

EVENT POST and EVENT WAIT

Statements: *The EVENT POST statement allows an image to notify another image that it can proceed to work on tasks that use common resources. The EVENT WAIT statement allows an image to wait on events posted by other images. They take the following forms:*

Syntax

```
EVENT POST (event-var [, sync-stat-list])
```

```
EVENT WAIT (event-var [, wait-spec-list])
```

event-var	Is a scalar variable of type EVENT_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV. It must not depend on the value of *stat-var* or *err-var*. It cannot be a coindexed variable in an EVENT WAIT statement.
sync-stat-list	Is `STAT=`*stat-var* or `ERRMSG=`*err-var*
stat-var	Is a scalar integer variable in which the status of the synchronization is stored.
err-var	Is a scalar default character variable in which explanatory text is stored if an error occurs.
wait-spec-list	Is *until-spec* or *sync-stat-list*
until-spec	Is `UNTIL_COUNT=` scalar-integer-expression.

Each specifier is optional and may appear at most once in a *sync-stat-list* or in a *wait-spec-list*.

Description

An EVENT POST statement atomically increments the value of *event-var* by one. Its value is processor dependent if an error condition occurs during the execution of an EVENT POST statement. The completion of an EVENT POST statement does not in any way depend on execution of a corresponding EVEN WAIT statement.

The following actions occur during the execution of an EVENT WAIT statement:

- If UNTIL_COUNT is not specified, the threshold value is one; otherwise, it is the maximum value of one and the specified scalar-integer-expression.
- The image executing the EVENT WAIT statement waits until the value of *event-var* is equal to or greater than the threshold value; otherwise, an error condition occurs.
- If no error condition has occurred, *event-var* is atomically decremented by the threshold value.

The value of *event-var* is processor dependent if an error condition occurs during the execution of an EVENT WAIT statement.

An EVEN POST statement execution is initially unsatisfied. The successful execution of an EVENT WAIT statement with a threshold value of *n* satisfies the first *n* unsatisfied EVENT POST statement executions for the specified *event-var*. The EVENT WAIT statement delays execution of the segment following the EVENT WAIT statement to execute after the segments which precede the first *n* EVENT POST statement executions for the specified *event-var*.

Example

The following example shows the use of EVENT POST and EVENT WAIT statements to synchronize each image with its left and right neighbor. Image 1 and image NUM_IMAGES() treat each other as left and right neighbors, conceptually laying the images out in a circle.

```
USE, INTRINSIC    :: ISO_FORTRAN_ENV
TYPE(EVENT_TYPE)  :: EVENT[*]
INTEGER           :: LEFT, RIGHT
...
IF ((THIS_IMAGE().NE. 1) .AND. (THIS_IMAGE() .NE. NUM_IMAGES()) THEN
  LEFT  = THIS_IMAGE() - 1
  RIGHT = THIS_IMAGE() + 1
ELSE IF (THIS_IMAGE() == 1) THEN
  LEFT  = NUM_IMAGES()
  RIGHT = 2
ELSE IF (THIS_IMAGE()== NUM_IMAGES()) THEN
  LEFT  = NUM_IMAGES() - 1
  RIGHT = 1
END IF

EVENT POST (EVENT[LEFT])            ! Signal left neighbor you got here
EVENT POST (EVENT[RIGHT])           ! Signal right neighbor you got here
EVENT WAIT (EVENT, UNTIL_COUNT = 2) ! Wait until your neighbors have both reached this point also
```

Using Coarrays

EVENT_QUERY

Intrinsic Subroutine (Generic): *Queries the event count of an event variable.*

Syntax

```
CALL EVENT_QUERY (event, count [, stat])
```

event	(Input) Must be an event variable of type EVENT_TYPE, and must not be coindexed. The event variable is accessed atomically with respect to the execution of EVENT POST statements in unordered segments, in exact analogy to atomic subroutines.
count	(Output) Must be an integer scalar with a decimal range no smaller than that of default integer. If no error condition occurs, count is assigned the value of the count of *event*, otherwise it is assigned the value -1.

stat	(Output; optional) Must be an integer scalar with a decimal exponent range of at least four. It must not be coindexed. If the *stat* argument is present, it is assigned a processor-dependent positive value if an error condition occurs, or zero if no error occurs. If an error occurs and *stat* is not present, error termination is initiated.

Example

Consider the following example:

```
CALL EVENT_QUERY (EVENT, COUNT)
```

If there have been six successful posts to EVENT, and 3 successful waits that did not specify UNTIL_COUNT= in the preceding segments, the variable COUNT will have the value 3. If there have been no successful posts or waits in the preceding segments, COUNT will have the value 0.

EVENT POST and EVENT WAIT

EXECUTE_COMMAND_LINE

Intrinsic Subroutine: *Executes a command line.*

Syntax

CALL EXECUTE_COMMAND_LINE (*command* [,*wait*,*exitstat*,*cmdstat*,*cmdmsg*])

command	(Input) Must be a scalar of type default character. It is the command line to be executed. The interpretation is processor dependent.
wait	(Input; optional) Must be a scalar of type logical. If *wait* is present with the value FALSE and the processor supports asynchronous execution of the command, the command is executed asynchronously; otherwise it is executed synchronously.
exitstat	(Inout; optional) Must be a scalar of type integer. If the command is executed synchronously, *exitstat* is assigned the value of the processor-dependent exit status of the executed command. Otherwise, the value of *exitstat* is unchanged.
cmdstat	(Output; optional) Must be a scalar of type integer. It is assigned one of the following values: • -1 if the processor does not support command line execution • A processor-dependent positive value if an error condition occurs • -2 if no error condition occurs but *wait* is present with the value FALSE and the processor does not support asynchronous execution. • 0 otherwise
cmdmsg	(Inout; optional) Must be a scalar of type default character. If an error condition occurs, *cmdmsg* is assigned a processor-dependent explanatory message. Otherwise, *cmdmsg* is unchanged.

Description

When *command* is executed synchronously, EXECUTE_COMMAND_LINE returns after the command line has completed execution. Otherwise, EXECUTE_COMMAND_LINE returns without waiting.

If a condition occurs that would assign a nonzero value to *cmdstat* but *cmdstat* is not present, execution is terminated.

NOTE
If the application has a standard console window, command output will appear in that window. On Windows* systems, if the application does not have a console window, including QuickWin applications, command output will not be shown.

Example

```
INTEGER :: CSTAT, ESTAT
CHARACTER(100) :: CMSG
CALL EXECUTE_COMMAND_LINE ("dir > dir.txt", EXITSTAT=ESTAT, &
           CMDSTAT=CSTAT, CMDMSG=CMSG)
IF (CSTAT > 0) THEN
  PRINT *, "Command execution failed with error ", TRIM(CMSG)
ELSE IF (CSTAT < 0) THEN
  PRINT *, "Command execution not supported"
ELSE
  PRINT *, "Command completed with status ", ESTAT
END IF
END
```

In the above example, EXECUTE_COMMAND_LINE is called to execute a "dir" command with output redirected to a file. Since the WAIT argument was omitted, the call waits for the command to complete and the command's exit status is returned in ESTAT. If the command cannot be executed, the error message returned in CMSG is displayed, but note that this is not based on the success or failure of the command itself.

EXIT Statement

Statement: *Terminates execution of a DO loop or a named construct.*

Syntax

`EXIT [`*`name`*`]`

name	(Optional) Is the name of the DO loop or construct.

Description

The EXIT statement causes execution of a DO loop or a named construct to be terminated.

If *name* is specified, the EXIT statement must be within the range of that named construct. Otherwise, the EXIT statement must be within a DO loop and it exits the innermost DO within which it appears.

If a DO loop is terminated, any inner DO loops are also terminated and the DO control variables retain their last value. If a non-DO construct is terminated, any DO loops inside that construct are also terminated.

An EXIT statement must not appear within a DO CONCURRENT construct if it belongs to that construct or an outer construct.

An EXIT statement must not appear in a CHANGE TEAM or CRITICAL construct if it belongs to an outer construct.

An EXIT statement can appear in any of the following constructs:

- ASSOCIATE
- BLOCK
- CHANGE TEAM
- CRITICAL
- DO
- IF

- SELECT CASE
- SELECT RANK
- SELECT TYPE

An EXIT statement cannot appear in a WHERE or FORALL construct.

Example

The following examples demonstrate EXIT statements.

Example 1:

```
LOOP_A : DO I = 1, 15
  N = N + 1
  IF (N > I) EXIT LOOP_A
END DO LOOP_A
```

Example 2:

```
    INTEGER numpoints, point
    REAL datarray(1000), sum
    sum = 0.0
    DO point = 1, 1000
      sum = sum + datarray(point)
      IF (datarray(point+1) .EQ. 0.0) EXIT
    END DO
```

Example 3:

```
DO I=1,N
   MyBlock:  BLOCK
    REAL :: T
    T = A(I) + B(I)
    IF (T == 0.0) EXIT MyBlock
    C(I) = T + SQRT(T)
    END BLOCK
END DO
```

Example 4:

```
DO CONCURRENT (I = 1:N)
   MyBlock:  BLOCK
     REAL :: T
    T = A(I) + B(I)
    IF (T == 0.0) EXIT MyBlock
    C(I) = T + SQRT(T)
    END BLOCK
END DO
```

The following example shows illegal EXIT statements in DO CONCURRENT and CRITICAL:

```
LOOP_1 : DO CONCURRENT (I = 1:N)
  N = N + 1
  IF (N > I) EXIT LOOP_1   ! cannot EXIT DO CONCURRENT
END DO LOOP_1

LOOP_2 : DO I = 1, 15
  CRITICAL
    N = N + 1
    IF (N > I) EXIT LOOP_2      ! cannot EXIT outer construct from inside
  END CRITICAL                  !   CHANGE TEAM, DO CONCURRENT, or CRITICAL
END DO LOOP_2
```

See Also

DO
DO WHILE

EXIT Subroutine

Intrinsic Subroutine (Generic): *Terminates program execution, closes all files, and returns control to the operating system. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL EXIT [( [status] )]
```

status	(Output; optional) Is an integer argument you can use to specify the image exit-status value.

The exit-status value may not be accessible after program termination in some application environments.

Example

```
    INTEGER(4) exvalue
! all is well, exit with 1
    exvalue = 1
    CALL EXIT(exvalue)
! all is not well, exit with diagnostic -4
    exvalue = -4
    CALL EXIT(exvalue)
! give no diagnostic, just exit
    CALL EXIT ( )
```

See Also

END
ABORT

EXP

Elemental Intrinsic Function (Generic): *Computes an exponential value.*

Syntax

```
result = EXP (x)
```

x	(Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*. The value of the result is e^{x}. If *x* is of type complex, its imaginary part is regarded as a value in radians.

Specific Name	Argument Type	Result Type
EXP	REAL(4)	REAL(4)
DEXP	REAL(8)	REAL(8)
QEXP	REAL(16)	REAL(16)
CEXP [1]	COMPLEX(4)	COMPLEX(4)

Specific Name	Argument Type	Result Type
CDEXP[2]	COMPLEX(8)	COMPLEX(8)
CQEXP	COMPLEX(16)	COMPLEX(16)

[1]The setting of compiler options specifying real size can affect CEXP.

[2]This function can also be specified as ZEXP.

Example

EXP (2.0) has the value 7.389056.

EXP (1.3) has the value 3.669297.

The following shows another example:

```
!  Given initial size and growth rate,
!  calculates the size of a colony at a given time.
     REAL sizei, sizef, time, rate
     sizei = 10000.0
     time = 40.5
     rate = 0.0875
     sizef = sizei * EXP (rate * time)
     WRITE (*, 100) sizef
100  FORMAT (' The final size is ', E12.6)
     END
```

See Also

EXP10
LOG

EXP10

Elemental Intrinsic Function (Generic): *Computes a base 10 exponential value.*

Syntax

```
result = EXP10 (x)
```

x (Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*. The value is 10 raised to the power of *x*. If *x* is of type complex, its imaginary part is regarded as a value in radians.

Specific Name	Argument Type	Result Type
EXP10	REAL(4)	REAL(4)
DEXP10	REAL(8)	REAL(8)
QEXP10	REAL(16)	REAL(16)
CEXP10 [1]	COMPLEX(4)	COMPLEX(4)
CDEXP10	COMPLEX(8)	COMPLEX(8)
CQEXP10	COMPLEX(16)	COMPLEX(16)

Specific Name	Argument Type	Result Type
[1]The setting of compiler options specifying real size can affect CEXP10.		

Example

EXP10 (2.0) has the value 100.00.

EXP10 (1.3) has the value 19.95262.

See Also

LOG10
EXP

EXPONENT

Elemental Intrinsic Function (Generic): *Returns the exponent part of the argument when represented as a model number.*

Syntax

`result = EXPONENT (x)`

x	(Input) must be of type real.

Results

The result type is default integer. If *x* is not equal to zero, the result value is the exponent part of *x*. The exponent must be within default integer range; otherwise, the result is undefined.

If *x* is zero, the exponent of *x* is zero. For more information on the exponent part (*e*) in the real model, see Model for Real Data.

Example

EXPONENT (2.0) has the value 2.

If 4.1 is a REAL(4) value, EXPONENT (4.1) has the value 3.

The following shows another example:

```
REAL(4) r1, r2
REAL(8) r3, r4
r1 = 1.0
r2 = 123456.7
r3 = 1.0D0
r4 = 123456789123456.7
write(*,*) EXPONENT(r1) ! prints 1
write(*,*) EXPONENT(r2) ! prints 17
write(*,*) EXPONENT(r3) ! prints 1
write(*,*) EXPONENT(r4) ! prints 47
END
```

EXTENDS_TYPE_OF

Inquiry Intrinsic Function (Generic): *Inquires whether the dynamic type of an object is an extension type of the dynamic type of another object.*

Syntax

`result = EXTENDS_TYPE_OF (a , mold)`

a	(Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.
mold	(Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.

Results

The result type is default logical scalar.

The following determines the result value:

- If *mold* is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .TRUE..
- If *a* is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is .FALSE..
- If the dynamic type of *a* or *mold* is extensible, the result is true only if the dynamic type of *a* is an extension type of the dynamic type of *mold*.

Otherwise, the result is processor dependent.

EXTERNAL

Statement and Attribute: *Allows an external procedure, a dummy procedure, a procedure pointer, or a block data subprogram to be used as an actual argument. (To specify intrinsic procedures as actual arguments, use the INTRINSIC attribute.)*

Syntax

The EXTERNAL attribute can be specified in a type declaration statement or an EXTERNAL statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] EXTERNAL [, *att-ls*] :: *ex-pro*[, *ex-pro*]...

Statement:

EXTERNAL [::]*ex-pro*[, *ex-pro*]...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
ex-pro	Is the name of an external (user-supplied) procedure, a dummy procedure, a procedure pointer, or block data subprogram.

Description

In a type declaration statement, only functions can be declared EXTERNAL. However, you can use the EXTERNAL statement to declare subroutines and block data program units, as well as functions, to be external.

The name declared EXTERNAL is assumed to be the name of an external procedure, even if the name is the same as that of an intrinsic procedure. For example, if SIN is declared with the EXTERNAL attribute, all subsequent references to SIN are to a user-supplied function named SIN, not to the intrinsic function of the same name.

You can include the name of a block data program unit in the EXTERNAL statement to force a search of the object module libraries for the block data program unit at link time. However, the name of the block data program unit must not be used in a type declaration statement.

If you want to describe a routine with greater detail, use the INTERFACE statement. This statement automatically declares a routine as EXTERNAL, and provides information on result types and argument types.

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

Example

The following example shows type declaration statements specifying the EXTERNAL attribute:

```
PROGRAM TEST
...
INTEGER, EXTERNAL :: BETA
LOGICAL, EXTERNAL :: COS
...
CALL SUB(BETA)       ! External function BETA is an actual argument
```

You can use a name specified in an EXTERNAL statement as an actual argument to a subprogram, and the subprogram can then use the corresponding dummy argument in a function reference or a CALL statement; for example:

```
EXTERNAL FACET
CALL BAR(FACET)
SUBROUTINE BAR(F)
EXTERNAL F
CALL F(2)
```

Used as an argument, a complete function reference represents a value, not a subprogram; for example, FUNC(B) represents a value in the following statement:

```
CALL SUBR(A, FUNC(B), C)
```

The following shows another example:

```
EXTERNAL MyFunc, MySub
C   MyFunc and MySub are arguments to Calc
    CALL Calc (MyFunc, MySub)
C   Example of a user-defined function replacing an
C   intrinsic
    EXTERNAL SIN
    x = SIN (a, 4.2, 37)
```

F_C_STRING

Intrinsic Module Function (Generic): *Creates a C null terminated string from a Fortran string.*

Module

USE, INTRINSIC :: ISO_C_BINDING

Syntax

`F_C_STRING (string[, asis])`

string	(Input) Is a scalar character of kind C_CHAR.
asis	(Optional, input) Is a LOGICAL scalar.

Results

The result is a scalar character of type C_CHAR. If *asis* is present and has the value .TRUE., the length parameter of the result has a value equal to LEN (*string*) + 1, and the result has the value equal to *string* // C_NULL_CHAR.

If *asis* is present with the value .FALSE., or if *asis* is not present, the length parameter of the result has a value equal to LEN (TRIM *stringstring*)) + 1, and the result has the value equal to TRIM (*string*) // C_NULL_CHAR.

Example

If STRING is declared as CHARACTER(LEN=7, KIND=C_CHAR) and it has the value "12345 " (two trailing blanks), then F_C_STRING () has the value "12345"//C_NULL_CHAR, and F_C_STRING (STRING, .TRUE.) has the value "12345 "//C_NULL_CHAR.

ISO_C_BINDING Module

FAIL IMAGE

Statement: *Causes the image that executes it to stop participating in program execution, without initiating termination.*

Syntax

`FAIL IMAGE`

This statement allows you to simulate image failure and to test and debug image failure recovery in a program, without requiring an actual image failure.

After execution of a FAIL IMAGE statement, no additional statements are executed by the image.

A FAIL IMAGE statement is not an image control statement.

The detection of a failed image may happen at different times in the execution of other images; for more information, see FAILED_IMAGES.

NOTE
If you use a FAIL IMAGE statement to make an image fail, you should use a STAT= specifier or a STAT argument in all coarray operations that might encounter that failed image if the statement or operation permits, or you should specify either the `assume failed_images` or `standard-semantics` compiler option. If you do not use a STAT= specifier, a STAT argument, or specify one of the compiler options, those operations will not check for failed images. They may then try to coordinate with the failed image, waiting for a response from it. The response would never happen and so the application would hang.

Examples

The following example demonstrates using the STAT= specifier to prevent an application hang (see Note above):

```
SUBROUTINE FAIL_AND_SYNC ( THIS_ONE )
   INTEGER THIS_ONE
   INTEGER MY_STAT
   IF (THIS_IMAGE() .EQ. THIS_ONE) THEN
       FAIL IMAGE
   END IF
   SYNC ALL (STAT=MY_STAT)      ! Would hang without STAT=
END SUBROUTINE FAIL_AND_SYNC
```

If an image calls the following procedure at regular time intervals, it has a one in ten thousand chance of failure in each time step:

```
SUBROUTINE RANDOM_FAILURE ()
   REAL RANDOM
   CALL RANDOM_NUMBER (RANDOM)
   IF (RANDOM > 0.9999) FAIL IMAGE
   RETURN
END SUBROUTINE RANDOM_FAILURE
```

See Also

FAILED_IMAGES
IMAGE_STATUS
`standard-semantics` compiler option
`assume [no]failed_images` compiler option

FAILED_IMAGES

Transformational Intrinsic Function (Generic):
Returns an array of index images that have failed.

Syntax

`result = FAILED_IMAGES ([team, kind])`

team	(Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.
kind	(Input; optional) Must be a scalar integer expression with a value that is a valid INTEGER kind type parameter.

Results

The result is a rank-one integer array with the same type kind parameters as *kind* if present; otherwise, default integer. The size of the array is equal to the number of images in the specified team that are known to have failed.

The result array elements are the image index values of images on the current team that are known to have failed. The indices are arranged in increasing numeric order.

If the image executing the FAILED_IMAGES reference previously executed a collective subroutine whose STAT argument returned the value STAT_FAILED_IMAGES defined in the intrinsic module ISO_FORTRAN_ENV, or if the image executed an image control statement whose STAT= specifier returned the value STAT_FAILED_IMAGE, at least one image in the team executing the collective or image control statement is known to have failed.

Failed images may lead to unavoidable hangs

Coarray programs are parallel programs, so between synchronization points the relative ordering of events in different images is unknown and undefined. The failure of an image or the execution of the FAIL IMAGE statement is such an event. It happens at a definite time in the image that fails, but the other images will discover the failure at different points in their execution. Also, because a failed image does not participate in synchronization points, it is possible for the discovery to happen before a synchronization point in one image and after it in another.

This means that when other images synchronize (such as with a SYNC ALL), it is possible that some will know that that image has failed and some will not. In this case, the images that don't know will attempt to synchronize with the failed image and the application will hang, making no progress.

There is no certain way to prevent a hang when an image fails. However, if you structure your program so that synchronizations points are infrequent, the chance of a failure happening just before a synchronization point is lower. If images frequently do coarray loads and stores, or check image status, they are more likely to discover a failed image sooner. The FAILED_IMAGES intrinsic will check for failed images, but other images might not get the same result from that call.

Example

If image 5 and 12 of the current team are known to have failed, the result of FAILED_IMAGES ( ) is an array of default integer type with size 2 defined with the value [5, 12]. If no images in the current team are known to have failed, the result of FAILED_IMAGES ( ) is a zero-sized array.

ISO_FORTRAN_ENV Module

FDATE

Portability Function and Subroutine: *Returns the current date and time as an ASCII string.*

Module

USE IFPORT

Syntax

Function Syntax

```
result = FDATE()
```

Subroutine Syntax:

```
CALL FDATE ( [string] )
```

string (Output; optional) Character*(*). It is returned as a 24-character string in the form:

```
Mon Jan 31 04:37:23 2001
```

Any value in *string* before the call is destroyed.

Results

The result of the function FDATE and the value of *string* returned by the subroutine FDATE(*string*) are identical. Newline and NULL are not included in the string.

When you use FDATE as a function, declare it as:

```
CHARACTER*24 FDATE
```

Example

```
USE IFPORT
CHARACTER*24 today
!
CALL FDATE(today)
write (*,*), 'Today is ', today
!
write (*,*), 'Today is ', fdate()
```

USE IFPORT

Syntax

`result = FGETC (lunit,char)`

lunit (Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.

char (Output) CHARACTER*1. Next available character in the file. If *lunit* is connected to a console device, then no characters are returned until the Enter key is pressed.

Results

The result type is INTEGER(4). The result is zero if the read is successful, or -1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:

EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).

If you use WRITE, READ, or any other Fortran I/O statements with *lunit*, be sure to read Portability Routines.

Example

```
USE IFPORT
CHARACTER inchar
INTEGER istatus
```

```
istatus = FGETC(5,inchar)
PRINT *, inchar
END
```

GETCHARQQ
READ

FINAL Clause

Parallel Directive Clause: *Specifies that the generated task will be a final task.*

Syntax

FINAL (*scalar-logical-expression*)

scalar-logical-expression	Is a scalar logical expression. When the expression evaluates to .TRUE., it specifies that the generated task will be a final task.

All task constructs encountered during execution of a final task will generate included tasks.

Note that if a variable is used in a FINAL clause expression of a directive construct, it causes an implicit reference to the variable in all enclosing constructs.

Only a single FINAL clause can appear in the directive.

FINAL Statement

Statement: *Denotes a finalization procedure that defines one or more final subroutines that are bound to a derived type.*

Syntax

The FINAL statement takes the following form:

FINAL [::] *sub1* [, *sub2*]...

sub1, sub2, ...	Is a final subroutine, which is a module procedure with exactly one dummy argument of the derived type. The dummy argument cannot be INTENT(OUT), it cannot have the VALUE attribute, it cannot be optional, and it cannot be a pointer, allocatable, or a coarray. All array shape and length type parameters are assumed.

Description

A final subroutine must not have a dummy argument with the same kind type parameters and rank as the dummy argument of another final subroutine of the type.

You cannot specify a subroutine that was previously specified as a final subroutine for the derived type.

If a final subroutine has an assumed-rank dummy argument, no other final subroutine of that type can have a dummy argument with the same kind type parameters.

This statement is used in derived-type type-bound procedures.

A derived type is finalizable only if it has a final subroutine or a nonpointer, nonallocatable component of finalizable type. A nonpointer data entity is finalizable only if it is of finalizable type.

When an entity is finalized, the following actions occur in this order:

1. If the dynamic type of the entity has a final subroutine whose dummy argument has the same kind type parameters and rank as the entity being finalized, it is called with the entity as an actual argument.

   Otherwise, if there is an elemental final subroutine whose dummy argument has the same kind type parameters as the entity being finalized, or a final subroutine whose dummy argument is assumed-rank with the same kind type parameters as the entity being finalized, it is called with the entity as an actual argument. Otherwise, no subroutine is called.
2. Finalizable components in the type are finalized. If the entity is an array, each finalizable component of each element is finalized. The order of finalization is processor dependent.
3. If the entity is of an extended type with a finalizable parent type, the parent component is finalized.

Effects of Finalization

If the variable of an intrinsic assignment is not an unallocated allocatable array when the statement is executed, the variable is finalized after the expression on the right-hand side (RHS) is evaluated and before the variable is defined. If the variable is an allocated allocatable variable or has an allocated allocatable subobject that would be deallocated by intrinsic assignment, finalization occurs before deallocation.

When a pointer is deallocated, its target is finalized. When an allocatable entity is deallocated, it is finalized unless it is the variable on the left-hand side (LHS) of the intrinsic assignment or a subobject of the variable.

A nonpointer, nonallocatable object that is not a dummy argument or function result is finalized immediately before it would become undefined due to execution of a RETURN or END statement.

If the entity is of extended type and the parent type is finalizable, the parent component is finalized.

A nonpointer, nonallocatable local variable of a BLOCK construct is finalized immediately before it would become undefined due to termination of the BLOCK construct.

The following rules also apply:

- If an executable construct references a nonpointer function, the result is finalized after execution of the innermost executable construct containing the reference.
- If a specification expression in a scoping unit references a function, the result is finalized before execution of the executable constructs in the scoping unit.
- A nonpointer, nonallocatable, INTENT(OUT) dummy argument of a procedure is finalized when the procedure is invoked before the dummy argument becomes undefined. Finalization of INTENT(OUT) dummy arguments occurs in the invoked procedure; for elemental procedures, an INTENT(OUT) argument will be finalized only if a scalar or elemental final subroutine is available, regardless of the rank of the argument.
- If image execution is terminated, either by an error or by execution of a ERROR STOP, STOP, or END PROGRAM statement, any entities that exist immediately before termination are not finalized.

Example

The following example declares two module subroutines to be final:

```
TYPE MY_TYPE
...   ! Component declarations
CONTAINS
  FINAL :: CLEAN1, CLEAN2
END TYPE MY_TYPE
```

Type-Bound Procedures

FIND

Statement: *Positions a direct access file at a particular record and sets the associated variable of the file to that record number. It is comparable to a direct access READ statement with no I/O list, and it can open an existing file. No data transfer takes place.*

Syntax

```
FIND ([UNIT=] io-unit, REC= r[, ERR= label] [, IOSTAT= i-var])

FIND (io-unit 'r [, ERR=label] [, IOSTAT=i-var])
```

io-unit	Is a logical unit number. It must refer to a relative organization file (see Unit Specifier).
r	Is the direct access record number. It cannot be less than one or greater than the number of records defined for the file (see Record Specifier).
label	Is the label of the executable statement that receives control if an error occurs.
i-var	Is a scalar integer variable that is defined as a positive integer if an error occurs, and as zero if no error occurs (see I/O Status Specifier).

Example

In the following example, the FIND statement positions logical unit 1 at the first record in the file. The file's associated variable is set to one:

```
  FIND(1, REC=1)
```

In the following example, the FIND statement positions the file at the record identified by the content of INDX. The file's associated variable is set to the value of INDX:

```
  FIND(4, REC=INDX)
```

Forms for Direct-Access READ Statements

I/O Control List

FINDLOC

Transformational Intrinsic Function (Generic): *Finds the location of a specified value in an array.*

Syntax

```
result = FINDLOC (array, value, dim [, mask, kind, back])

result = FINDLOC (array, value[, mask, kind, back])
```

array	(Input) Must be an array of intrinsic type.
value	(Input) Must be scalar and in type conformance with *array*. If only one element matches *value*, that element's subscripts are returned.

	If more than one element matches *value* and *back* is absent or present with the value .FALSE., the element whose subscripts are returned is the first element, taken in array element order. If *back* is present with the value .TRUE., the element whose subscripts are returned is the last element, taken in array element order.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.
kind	(Input; optional) Must be a scalar integer constant expression.
back	(Input; optional) Must be a scalar of type logical.

If both *array* and *value* are of type logical, the comparison is performed with the .EQV. operator; otherwise, the comparison is performed with the == operator. If the value of the comparison is true, that element of *array* matches *value*.

Results

The result is integer. If *kind* is present, the kind type parameter is that specified by the value of *kind*. Otherwise, the kind type parameter is that of default integer type.

If *dim* does not appear, the result is an array of rank one and of size equal to the rank of *array*; otherwise, the result is of rank *n* - 1 and shape (d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n), where (d_1, d_2,...d_n) is the shape of *array*.

The result of FINDLOC (*array*, *valuevalue*) is a rank-one array whose element values are the values of the subscripts of an element of *array* whose value matches *value*. If there is such a value, the *i*th subscript returned is in the range 1 to e_i, where e_i is the extent of the *i*th dimension of *array*. If no elements match *value* or if *array* has size zero, all elements of the result are zero.

The result of FINDLOC (*array*, *value*, MASK = *mask*) is a rank-one array whose element values are the values of the subscripts of an element of *array*, corresponding to a true element of *mask*, whose value matches *value*. If there is such a value, the *i*th subscript returned is in the range 1 to e_i, where e_i is the extent of the *i*th dimension of *array*. If no elements match *value*, or *array* has size zero, or every element of *mask* has the value .FALSE., all elements of the result are zero.

If *array* has rank one, the result of FINDLOC (*array*, *value*, DIM = *dim* [, MASK = *mask*]) is a scalar whose value is equal to that of the first element of FINDLOC (*array*, *value* [, MASK = *mask*]). Otherwise, the value of element (s_1, s_2,...s_{dim-1}, s_{dim+1},...s_n) of the result is equal to FINDLOC (*array* (s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n), *value*, DIM = 1 [, MASK = *mask* (s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n)]).

The setting of compiler options specifying integer size can affect this function.

Examples

The value of FINDLOC ([2, 6, 4, 6], VALUE = 6) is [2].

The value of FINDLOC ([2, 6, 4, 6], VALUE = 6, BACK = .TRUE.) is [4].

If A has the value

```
[ 0  -5   7   7 ]
[ 3   4  -1   2 ]
[ 1   5   6   7 ]
```

and M has the value

```
[ T   T   F   T ]
[ T   T   F   T ]
[ T   T   F   T ]
```

then FINDLOC (A, 7, MASK = M) is [1, 4] and FINDLOC (A, 7, MASK = M, BACK = .TRUE.) is [3, 4].

This is independent of the declared lower bounds for A.

The value of FINDLOC ([2, 6, 4], VALUE = 6, DIM = 1) is 2.

If B has the value

```
[ 1   2   -9 ]
[ 2   3    6 ]
```

then FINDLOC (B, VALUE = 2, DIM = 1) is [2, 1, 0] and FINDLOC (B, VALUE = 2, DIM = 2) is [2, 1].

This is independent of the declared lower bounds for B.

MAXLOC
MINLOC

FINDFILEQQ

Portability Function: *Searches for a specified file in the directories listed in the path contained in the environment variable.*

Module

USE IFPORT

Syntax

`result = FINDFILEQQ (filename,varname,pathbuf)`

filename	(Input) Character*(*). Name of the file to be found.
varname	(Input) Character*(*). Name of an environment variable containing the path to be searched.
pathbuf	(Output) Character*(*). Buffer to receive the full path of the file found.

Results

The result type is INTEGER(4). The result is the length of the string containing the full path of the found file returned in *pathbuf*, or 0 if no file is found.

Example

```
USE IFPORT
CHARACTER(256) pathname
INTEGER(4) pathlen
pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)
WRITE (*,*) pathname
END
```

FIRSTPRIVATE

Parallel Directive Clause: *Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.*

Syntax

`FIRSTPRIVATE (list)`

list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different threads are initialized to the value the variable had upon entering the parallel region.

To avoid race conditions, which are caused by unintended sharing of data, concurrent updates of the original variable must be synchronized with the read of the original variable that occurs as a result of the FIRSTPRIVATE clause.

If the original variable has the POINTER attribute, the new variable receives the same association status of the original variable as if by pointer assignment.

If the original variable does not have the POINTER attribute, initialization of the new variable occurs as if by intrinsic assignment, unless the original variable has the allocation status of "not currently allocated". In this case, the new variable also has the status of " not currently un allocated".

The following are restrictions for the FIRSTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a FIRSTPRIVATE clause.
- A variable that is private within a parallel region must not appear in a FIRSTPRIVATE clause in a worksharing construct if any of the worksharing regions arising from the worksharing construct ever bind to any of the parallel regions arising from the parallel construct.
- A variable that appears in a REDUCTION clause of a PARALLEL construct must not appear in a FIRSTPRIVATE clause in a worksharing or task construct if any of the worksharing or task regions arising from the worksharing or task construct ever bind to any of the parallel regions arising from the parallel construct.
- A variable that appears in a REDUCTION clause in a WORKSHARE construct must not appear in a FIRSTPRIVATE clause in a task construct encountered during execution of any of the worksharing regions arising from the worksharing construct.
- Assumed-size arrays must not appear in a PRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
- If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

NOTE
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE..

Example

Consider the following:

```
A = 3
B = 4
!$OMP PARALLEL PRIVATE(A) FIRSTPRIVATE(B)
```

In this case, variable A has an undefined value at the beginning of the parallel region. However, variable B has the value 4, which was specified in the serial region preceding the parallel region.

PRIVATE clause
LASTPRIVATE clause

FIXEDFORMLINESIZE

General Compiler Directive: *Sets the line length for fixed-form Fortran source code.*

Syntax

```
!DIR$ FIXEDFORMLINESIZE:{72 | 80 | 132}
```

You can set FIXEDFORMLINESIZE to 72 (the default), 80, or 132 characters. The FIXEDFORMLINESIZE setting remains in effect until the end of the file, or until it is reset.

The FIXEDFORMLINESIZE directive sets the source-code line length in include files, but not in USE modules, which are compiled separately. If an include file resets the line length, the change does not affect the host file.

This directive has no effect on free-form source code.

Example

```
!DIR$ NOFREEFORM
!DIR$ FIXEDFORMLINESIZE:132
      WRITE (*,*) 'Sentence that goes beyond the 72nd column without continuation.'
```

Equivalent Compiler Options

FLOAT

Elemental Intrinsic Function (Generic): *Converts an integer to REAL(4).*

See Also

REAL

FLOOR

Elemental Intrinsic Function (Generic): *Returns the greatest integer less than or equal to its argument.*

Syntax

```
result = FLOOR (a[,kind])
```

a	(Input) Must be of type real.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the greatest integer less than or equal to *a*.

The setting of compiler options specifying integer size can affect this function.

Example

FLOOR (4.8) has the value 4.

FLOOR (-5.6) has the value -6.

The following shows another example:

```
I = FLOOR(3.1)  ! returns 3
I = FLOOR(-3.1) ! returns -4
```

See Also

CEILING

FLUSH Directive

OpenMP* Fortran Compiler Directive: *Identifies synchronization points at which the threads in a team must provide a consistent view of memory.*

Syntax

```
!$OMP FLUSH [(list)]
```

list	Is the name of one or more variables to be flushed. Names must be separated by commas.

The binding thread set for a FLUSH construct is the encountering thread.

The FLUSH directive must appear at the precise point in the code at which the synchronization is required. To avoid flushing all variables, specify a *list*.

Thread-visible variables are written back to memory at the point at which this directive appears. Modifications to thread-visible variables are visible to all threads after this point. Subsequent reads of thread-visible variables fetch the latest copy of the data.

Thread-visible variables include the following data items:

- Globally visible variables (common blocks and modules)
- Local variables that do not have the SAVE attribute but have had their address taken and saved or have had their address passed to another subprogram
- Local variables that do not have the SAVE attribute that are declared shared in a parallel region within the subprogram
- Dummy arguments
- All pointer dereferences

The FLUSH directive is implied for the following directives (unless the NOWAIT keyword is used):

- ATOMIC and END ATOMIC
- BARRIER

- CRITICAL and END CRITICAL
- END DO
- END PARALLEL
- END SECTIONS
- END SINGLE
- END WORKSHARE
- ORDERED and END ORDERED
- PARALLEL and END PARALLEL
- PARALLEL DO and END PARALLEL DO
- PARALLEL SECTIONS and END PARALLEL SECTIONS
- TARGET
- TARGET DATA
- TARGET ENTER DATA on entry
- TARGET EXIT DATA on exit
- TARGET UPDATE on entry if TO is present and on exit if FROM is present

These directives are only available on Linux* systems: TARGET, TARGET DATA, TARGET ENTER DATA, TARGET EXIT DATA, TARGET UPDATE.

Example

The following example uses the FLUSH directive for point-to-point synchronization between pairs of threads:

```
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(ISYNC)
      IAM = OMP_GET_THREAD_NUM( )
      ISYNC(IAM) = 0
!$OMP BARRIER
      CALL WORK( )
C I AM DONE WITH MY WORK, SYNCHRONIZE WITH MY NEIGHBOR
      ISYNC(IAM) = 1
!$OMP FLUSH(ISYNC)
C WAIT TILL NEIGHBOR IS DONE
      DO WHILE (ISYNC(NEIGH) .EQ. 0)
!$OMP FLUSH(ISYNC)
      END DO
!$OMP END PARALLEL
```

OpenMP Fortran Compiler Directives

Syntax Rules for Compiler Directives

Parallel Processing Model for information about Binding Sets

FLUSH Statement

Statement: *Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. It takes one of the following forms:*

Syntax

`FLUSH([UNIT=]`*`io-unit`* `[, ERR=`*`label`*`] [, IOMSG=`*`msg-var`*`] [IOSTAT=`*`i-var`*`])`

`FLUSH` *`io-unit`*

`io-unit`	(Input) Is an external unit specifier.
`label`	(Input) Is the label of the branch target statement that receives control if an error occurs.

msg-var	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
i-var	(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

The FLUSH statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

This statement has no effect on file position.

FLUSH Subroutine

Portability Subroutine: *Flushes the contents of an external unit buffer into its associated file.*

Module

USE IFPORT

Syntax

```
CALL FLUSH (lunit)
```

lunit	(Input) INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.

NOTE
The flush is performed in a non-blocking mode. In this mode, the command may return before the physical write is completed. If you want to use a blocking mode of FLUSH use COMMITQQ.

See Also

COMMITQQ

FMA and NOFMA

General Compiler Directives: *Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions. NOFMA disables the generation of FMA instructions.*

Syntax

```
!DIR$ FMA
```

```
!DIR$ NOFMA
```

These directives affect the current program unit but they also apply to subsequent program units in the source file, unless and until a program unit containing another FMA or NOFMA directive is encountered.

Once a NOFMA directive has been specified, it is in effect from that point forward. The setting impacts later routines in the source file. For example, consider that the following are in the same source file:

```
    real function fms_mul2( a,  b,  c,  d)
      implicit none
      real :: a, b, c, d
!       the default !dir$ fma leads to fma generation:
!       this is transformed into FMS(a,b,FMA(c,d,0))
```

```
!dir$ nofma
      fms_mul2 = a*b - c*d               ! no fma generation here
    end function fms_mul2

    real function fms_mul( a,  b,  c,  d)
      implicit none
      real :: a, b, c, d
      fms_mul = (a*b) - (c*d)            ! no fma generation here
    end function fms_mul
```

The NOFMA directive specified in `fms_mul2` will also impact the routine `fms_mul`. You must explicitly specify the FMA directive to override the effect of the NOFMA directive.

`fp-model strict, fp:strict` compiler option

FOR_DESCRIPTOR_ASSIGN

Runtime Subroutine: *Creates an array descriptor in memory. This routine is only available for Windows.*

Module

USE IFCORE

Syntax

`CALL FOR_DESCRIPTOR_ASSIGN (dp,base,size,reserved,rank,dims_info)`

dp	(Input) A Fortran pointer to an array; the array can be of any data type.
base	(Input) INTEGER(4) or INTEGER(8). The base address of the data being described by *dp*. Note that a Fortran pointer describes both the location and type of the data item.
size	(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).
reserved	(Input) INTEGER(4). A logical bitwise OR combination of the following constants, which are defined in `IFCORE.F90`: • FOR_DESCRIPTOR_ARRAY_DEFINED - Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.

- FOR_DESCRIPTOR_ARRAY_NODEALLOC - Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

```
integer, pointer :: p(:)
integer, target :: t
p => t   ! t cannot be deallocated
allocate(p(10)) ! t can be deallocated
```

  If the bit is set, the array cannot be deallocated.
- FOR_DESCRIPTOR_ARRAY_CONTIGUOUS - Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

rank (Input) INTEGER(4). The rank of the array pointed to.

dims_info (Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```
TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND  !Lower bound for the dimension
  INTEGER(4) UPPERBOUND  !Upper bound for the dimension
  INTEGER(4) STRIDE      !Stride for the dimension
END TYPE FOR_DIMS_INFO
```

The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

Example

```
use IFCORE
common/c_array/ array
real(8) array(5,5)
external  init_array
external  c_print_array
real(8),pointer :: p_array(:,:)
type(FOR_DIMS_INFO) dims_info(2)
 call init_array()

 do i=1,5
   do j=1,5
      print *,i,j, array(i,j)
   end do
 end do

 dims_info(1)%LOWERBOUND = 11
 dims_info(1)%UPPERBOUND = 15
 dims_info(1)%STRIDE = 1

 dims_info(2)%LOWERBOUND = -5
 dims_info(2)%UPPERBOUND = -1
 dims_info(2)%STRIDE = 1
```

```
 call FOR_DESCRIPTOR_ASSIGN(p_array, &
   LOC(array), &
   SIZEOF(array(1,1)), &
   FOR_DESCRIPTOR_ARRAY_DEFINED .or. &
   FOR_DESCRIPTOR_ARRAY_NODEALLOC .or. &
   FOR_DESCRIPTOR_ARRAY_CONTIGUOUS,  &
   2, &
   dims_info )

p_array = p_array + 1
call c_print_array()
end
```

The following shows the C program containing init_array and c_print_array:

```
#include <stdio.h>
#if !defined(_WIN32) && !defined(_WIN64)
#define C_ARRAY c_array_
#define INIT_ARRAY init_array_
#define C_PRINT_ARRAY c_print_array_
#endif
double C_ARRAY[5][5];
void INIT_ARRAY(void);
void C_PRINT_ARRAY(void);
void INIT_ARRAY(void)
{
  int i,j;
  for(i=0;i<5;i++)
     for(j=0;j<5;j++)
       C_ARRAY[i][j] = j + 10*i;
}
void C_PRINT_ARRAY(void)
{
   int i,j;
   for(i=0;i<5;i++){
     for(j=0;j<5;j++)
         printf("%f ", C_ARRAY[i][j]);
     printf("\n");
   }
}
```

POINTER - Fortran

FOR_GET_FPE

Runtime Function: *Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.*

Module

USE IFCORE

Syntax

```
result = FOR_GET_FPE( )
```

Results

The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFPORT module file.

To set floating-point exception flags after program initialization, use FOR_SET_FPE.

Example

```
USE IFCORE
INTEGER*4 FPE_FLAGS
FPE_FLAGS = FOR_GET_FPE ( )
```

See Also

FOR_SET_FPE

FOR_IFCORE_VERSION

Portability Function: *Returns the version of the Fortran runtime library (ifcore).*

Module

USE IFPORT

Syntax

`result = FOR_IFCORE_VERSION (`*`string`*`)`

string	(Output) Character*(*). The version information for the Fortran runtime library (ifcore).

Results

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If *string* is not long enough to contain the version information, the result is truncated on the right. If *string* is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

Example

Consider the following:

```
program what_ifcore
    use ifport
    integer       :: res
    character*56  :: str

    res = for_ifcore_version( str )
    print ("(3A)"), "'", str, "'"

end program what_ifcore
```

The above example will produce a result similar to the following, depending on spacing and the actual version information:

```
'Intel Fortran RTL Core Library Vvv.m-eeeMmm dd yyyy    '
```

where:

vv	Is a major version number

m	Is a minor version number
eee	Is an edit number
Mmm	Is a three-character abbreviation for the month
dd	Is a two-digit day of the month
yyyy	Is a four-digit year

See Also

FOR_IFCORE_VERSION

FOR_IFPORT_VERSION

Portability Function: *Returns the version of the Fortran portability library (ifport).*

Module

USE IFPORT

Syntax

```
result = FOR_IFPORT_VERSION (string)
```

string	(Output) Character*(*). The version information for the Fortran portability library (ifport).

Results

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If *string* is not long enough to contain the version information, the result is truncated on the right. If string is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

Example

Consider the following:

```
program what_ifport
    use ifport
    integer       :: res
    character*56  :: str

    res = for_ifport_version( str )
    print ("(3A)"), "'", str, "'"

end program what_ifport
```

The above example will produce a result similar to the following, depending on spacing and the actual version information:

```
'Intel Fortran portability library      Vvv.m-eeeMmm dd yyyy '
```

where:

vv	Is a major version number
m	Is a minor version number
eee	Is an edit number

Mmm	Is a three-character abbreviation for the month
dd	Is a two-digit day of the month
yyyy	Is a four-digit year

FOR_IFPORT_VERSION

FOR_LFENCE

Runtime Subroutine: *Inserts a memory load fence instruction that ensures completion of preceding load instructions.*

Module

USE IFCORE

Syntax

```
CALL FOR_LFENCE ()
```

Using this subroutine guarantees that in program order, every load instruction that precedes the load fence instruction is globally visible before any load instruction that follows the load fence.

FOR_MFENCE

Runtime Subroutine: *Inserts a memory fence instruction that ensures completion of all preceding load and store instructions.*

Module

USE IFCORE

Syntax

```
CALL FOR_MFENCE ()
```

Using this subroutine guarantees that in program order, every load and store instruction that precedes the memory fence instruction is globally visible before any load or store instruction that follows the memory fence can proceed.

for_rtl_finish_

Runtime Function: *Cleans up the Fortran runtime environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.*

Syntax

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```
result = for_rtl_finish_ ( )
```

Results

The result is an I/O status value. For information on these status values, see Use the IOSTAT Specifier and Fortran Exit Codes

To initialize the Fortran runtime environment, use function for_rtl_init_ .

Example

Consider the following C code:

```
int io_status;
int for_rtl_finish_ ( );
io_status = for_rtl_finish_ ( );
```

See Also

for_rtl_init_

for_rtl_init_

Runtime Subroutine: *Initializes the Fortran runtime environment and causes Fortran procedures and subroutines to behave the same as when called from a Fortran main program. On Linux*, it also establishes handlers and floating-point exception handling.*

Syntax

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```
CALL for_rtl_init_ (argcount,actarg)
```

argcount	Is a command-line parameter describing the argument count.
actarg	Is a command-line parameter describing the actual arguments.

To clean up the Fortran runtime environment, use function for_rtl_finish_.

Example

Consider the following C code:

```
int argc;
char **argv;
void for_rtl_init_ (int *, char **);
for_rtl_init_ (&argc, argv);
```

See Also

for_rtl_finish_

FOR_SET_FPE

Runtime Function: *Sets the floating-point exception flags. This routine can be called from a C or Fortran program.*

Module

USE IFCORE

Syntax

```
result = FOR_SET_FPE (a)
```

a	Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

Results

The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file.

To get the current settings of the floating-point exception flags, use FOR_GET_FPE.

Example

```
USE IFCORE
INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS
OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
```

The following example program is compiled without any `fpe` options. However, it uses calls to `for_set_fpe` to enable the same flags as when compiling with option `fpe:0`. The new flags can be verified by compiling the program with option `-fpe:0`.

```
   program samplefpe
   use ifcore
   implicit none

   INTEGER(4) :: ORIGINAL_FPE_FLAGS, NEW_FPE_FLAGS
   INTEGER(4) :: CURRENT_FPE_FLAGS, PREVIOUS_FPE_FLAGS

   NEW_FPE_FLAGS = FPE_M_TRAP_UND + FPE_M_TRAP_OVF + FPE_M_TRAP_DIV0  &
     + FPE_M_TRAP_INV + FPE_M_ABRUPT_UND + FPE_M_ABRUPT_DMZ
   ORIGINAL_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
   CURRENT_FPE_FLAGS = FOR_GET_FPE ()

   print *,"The original FPE FLAGS were:"
   CALL PRINT_FPE_FLAGS(ORIGINAL_FPE_FLAGS)

   print *," "   print *,"The new FPE FLAGS are:"
   CALL PRINT_FPE_FLAGS(CURRENT_FPE_FLAGS)

!! restore the fpe flag to their original values
   PREVIOUS_FPE_FLAGS = FOR_SET_FPE (ORIGINAL_FPE_FLAGS)

   end

   subroutine PRINT_FPE_FLAGS(fpe_flags)
   use ifcore
   implicit none
   integer(4)   :: fpe_flags
   character(3) :: toggle

   print 10, fpe_flags, fpe_flags
10 format(X,'FPE FLAGS = 0X',Z8.8," B'",B32.32)

   if ( IAND(fpe_flags, FPE_M_TRAP_UND) .ne. 0 ) then
     toggle = "ON"
   else
     toggle = "OFF"
   endif
   write(*,*) "  FPE_TRAP_UND    :", toggle

   if ( IAND(fpe_flags, FPE_M_TRAP_OVF) .ne. 0 ) then
     toggle = "ON"
   else
     toggle = "OFF"
   endif
   write(*,*) "  FPE_TRAP_OVF    :", toggle

   if ( IAND(fpe_flags, FPE_M_TRAP_DIV0) .ne. 0 ) then
```

```
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_TRAP_DIV0   :", toggle

  if ( IAND(fpe_flags, FPE_M_TRAP_INV) .ne. 0 ) then
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_TRAP_INV    :", toggle

  if ( IAND(fpe_flags, FPE_M_ABRUPT_UND) .ne. 0 ) then
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_ABRUPT_UND  :", toggle

  if ( IAND(fpe_flags, FPE_M_ABRUPT_OVF) .ne. 0 ) then
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_ABRUPT_OVF  :", toggle

  if ( IAND(fpe_flags, FPE_M_ABRUPT_DMZ) .ne. 0 ) then
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_ABRUPT_DIV0 :", toggle

  if ( IAND(fpe_flags, FPE_M_ABRUPT_DIV0) .ne. 0 ) then
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_ABRUPT_INV  :", toggle

  if ( IAND(fpe_flags, FPE_M_ABRUPT_DMZ) .ne. 0 ) then ! ABRUPT_DMZ
    toggle = "ON"
  else
    toggle = "OFF"
  endif
  write(*,*) "  FPE_ABRUPT_DMZ  :", toggle, "  (ftz related)"

  end subroutine PRINT_FPE_FLAGS
```

The following shows the output from the above program:

```
>ifx set_fpe_sample01.f90
>set_fpe_sample01.exe
 The original FPE FLAGS were:
 FPE FLAGS = 0X00000000 B'00000000000000000000000000000000
   FPE_TRAP_UND    :OFF
   FPE_TRAP_OVF    :OFF
   FPE_TRAP_DIV0   :OFF
```

```
   FPE_TRAP_INV    :OFF
   FPE_ABRUPT_UND  :OFF
   FPE_ABRUPT_OVF  :OFF
   FPE_ABRUPT_DIV0 :OFF
   FPE_ABRUPT_INV  :OFF
   FPE_ABRUPT_DMZ  :OFF (ftz related)

 The new FPE FLAGS are:
 FPE FLAGS = 0X0011000F B'00000000000100010000000000001111
   FPE_TRAP_UND    :ON
   FPE_TRAP_OVF    :ON
   FPE_TRAP_DIV0   :ON
   FPE_TRAP_INV    :ON
   FPE_ABRUPT_UND  :ON
   FPE_ABRUPT_OVF  :OFF
   FPE_ABRUPT_DIV0 :ON
   FPE_ABRUPT_INV  :OFF
   FPE_ABRUPT_DMZ  :ON (ftz related)
```

The following example builds a library that has to have a particular setting of the fpe flags internally, and has to work with user programs built with any combination of the fpe flags.

```
    !-- file USE.F90 starts here
subroutine use_subnorms
    use, intrinsic :: ieee_arithmetic
    use ifcore

    use, intrinsic :: ieee_features, only: ieee_subnormal

    call use_subnorms      ! Will also flush, but WON'T use subnorms!

end program example
    !-- end of file MAIN.F90
```

You can specify the following lines to compile and link the above program:

```
ifx -c -fpic -no-ftz -fpe3   use.f90
ifx -c -fpic -ftz            flush.f90
ifx -c -fpic                 main.f90
ifx -o main.exe main.o use.o flush.o
```

FOR_SET_FTN_ALLOC

Runtime Function: *Lets you specify your own routine to dynamically allocate common blocks. This function is especially useful when you are sharing libraries.*

Syntax

`result = FOR_SET_FTN_ALLOC(alloc_routine)`

alloc_routine	(Input) Character. Is the name of a user-defined allocation routine. The routine takes the same arguments as the routine prototype _FTN_ALLOC, which is defined in module IFCORE. For more information on _FTN_ALLOC and its arguments, see Allocating Common Blocks.

Results

The result has the same type as the type of the argument. The return value is a pointer to the previous allocation routine you specified for allocation of COMMONs, or to a null pointer if you did not specify a previous allocation routine.

The caller of FOR_SET_FTN_ALLOC must include a USE IFCOMMONALLOC statement. The allocation routine should include ISO_C_BINDING so it can correctly declare the arguments.

This function takes precedence over _FTN_ALLOC.

Example

The following shows an example of a user-defined routine that can be used with FOR_SET_FTN_ALLOC.

Note that you must compile the program using option `[Q]dyncom` to name the commons you want to be dynamically allocated.

```
! User's allocation routine
!
subroutine my_Fortran_alloc_routine (mem, size, name)
    use, intrinsic               :: ISO_C_BINDING
    implicit none

    type(C_PTR),    intent(OUT)         :: mem
    integer(C_INT), intent(INOUT)       :: size
    character, dimension(*), intent(IN) :: name

    ! Users would put their allocation code here.  This example text
    ! does not contain code to allocate memory.

end subroutine my_Fortran_alloc_routine

! This routine uses module IFCOMMONALLOC to swap allocation
! routines for dynamic COMMONs.
!
subroutine swap_alloc_routines( for_old )
    use ifcommonalloc
    use, intrinsic :: ISO_C_BINDING
    implicit none

    logical for_old

    ! The routine to use, defined above.
    !
    procedure(alloc_rtn) :: my_Fortran_alloc_routine

    ! Where to save the old one.
    !
    type(C_FUNPTR) :: saved_alloc_routine

    ! Do the swap
    !
    print *, "my_Fortran_alloc_routine"
    if (for_old) then
        saved_alloc_routine = set_ftn_alloc( C_FUNLOC(my_Fortran_alloc_routine) )
    else
        saved_alloc_routine = set_ftn_alloc( saved_alloc_routine )
    end if

end subroutine swap_alloc_routines

! Routines with dynamic commons would go here
```

```
! The main program doesn't need to know about module IFCOMMONALLOC.
!
program main
    implicit none

    ! Dynamic commons in routines first called in this region will use the
    !   default allocation method.

    swap_alloc_routines( .true. )

    ! Dynamic commons in routines first called in this region will use
    !   my_Fortran_alloc_routine.

    swap_alloc_routines( .false. )

    ! Dynamic commons in routines first called in this region will use the
    !   default allocation method.

end program main
```

FOR_SET_REENTRANCY

Runtime Function: *Controls the type of reentrancy protection that the Fortran Runtime Library (RTL) exhibits. This routine can be called from a C or Fortran program.*

Module

USE IFCORE

Syntax

`result = FOR_SET_REENTRANCY (mode)`

mode Must be of type INTEGER(4) and contain one of the following options:

FOR_K_REENTRANCY_NONE	Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will *not* be reentered due to asynchronous system traps (ASTs) or threads within the application.
FOR_K_REENTRANCY_ASYNCH	Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.
FOR_K_REENTRANCY_THREADED	Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.

FOR_K_REENTRANCY_INFO	Tells the Fortran RTL to return the current reentrancy mode.

Results

The result type is INTEGER(4). The return value represents the previous setting of the Fortran Runtime Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in which case the return value represents the current setting.

You must be using an RTL that supports the level of reentrancy you desire. For example, FOR_SET_REENTRANCY ignores a request for thread protection (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe RTL.

Example

```
PROGRAM SETREENT
USE IFCORE
INTEGER*4    MODE
CHARACTER*10 REENT_TXT(3) /'NONE    ','ASYNCH  ','THREADED'/
PRINT*,'Setting Reentrancy mode to ',REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
PRINT*,'Previous Reentrancy mode was ',REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
PRINT*,'Current Reentrancy mode is ',REENT_TXT(MODE+1)
END
```

FOR_SFENCE

Runtime Subroutine: *Inserts a memory store fence instruction that ensures completion of preceding store instructions.*

Module

USE IFCORE

Syntax

```
CALL FOR_SFENCE ()
```

Using this subroutine guarantees that in program order, every store instruction that precedes the store fence instruction is globally visible before any store instruction that follows the store fence.

FORALL

Statement and Construct: *The FORALL statement and construct is an element-by-element generalization of the masked array assignment in the WHERE statement and construct. It allows more general array shapes to be assigned, especially in construct form. The FORALL construct is an obsolescent language feature in Fortran 2018.*

Syntax

Statement:

```
FORALL (triplet-spec[, triplet-spec] ...[, mask-expr]) assign-stmt
```

Construct:

```
[name:] FORALL (triplet-spec[, triplet-spec] ...[, mask-expr])
   forall-body-stmt
```

```
   [forall-body-stmt]...
END FORALL [name]
```

triplet-spec

Is a triplet specification with the following form:

`[type::] subscript-name = subscript-1: subscript-2[: stride]`

The *type* is an optional integer data type. If *type* appears, the *subscript-name* has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If *type* does not appear, the *subscript-name* must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.

The *subscript-name* is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The *subscript*s and *stride* cannot contain a reference to any *subscript-name* in *triplet-spec*.

The *stride* cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

mask-expr

Is a logical array expression (called the mask expression). If it is omitted, the value .TRUE. is assumed. The mask expression can reference the subscript name in *triplet-spec*.

Description

If a construct name is specified in the FORALL statement, the same name must appear in the corresponding END FORALL statement.

A FORALL statement is executed by first evaluating all bounds and stride expressions in the triplet specifications, giving a set of values for each subscript name. The FORALL assignment statement is executed for all combinations of subscript name values for which the mask expression is true.

The FORALL assignment statement is executed as if all expressions (on both sides of the assignment) are completely evaluated before any part of the left side is changed. Valid values are assigned to corresponding elements of the array being assigned to. No element of an array can be assigned a value more than once.

A FORALL construct is executed as if it were multiple FORALL statements, with the same triplet specifications and mask expressions. Each statement in the FORALL body is executed completely before execution begins on the next FORALL body statement.

Any procedure referenced in the mask expression or FORALL assignment statement must be pure.

Pure functions can be used in the mask expression or called directly in a FORALL statement. Pure subroutines cannot be called directly in a FORALL statement, but can be called from other pure procedures.

Starting with Fortran 2018, the FORALL statement and construct are obsolescent features.

Example

The following example, which is not expressible using array syntax, sets diagonal elements of an array to 1:

```
REAL, DIMENSION(N, N) :: A
FORALL (I=1:N)  A(I, I) = 1
```

Consider the following:

```
FORALL(I = 1:N, J = 1:N, A(I, J) .NE. 0.0) B(I, J) = 1.0 / A(I, J)
```

This statement takes the reciprocal of each nonzero element of array A(1:N, 1:N) and assigns it to the corresponding element of array B. Elements of A that are zero do not have their reciprocal taken, and no assignments are made to corresponding elements of B.

Every array assignment statement and WHERE statement can be written as a FORALL statement, but some FORALL statements cannot be written using just array syntax. For example, the preceding FORALL statement is equivalent to the following:

```
WHERE(A /= 0.0) B = 1.0 / A
```

However, the following FORALL example cannot be written using just array syntax:

```
FORALL(I = 1:N, J = 1:N) H(I, J) = 1.0/REAL(I + J - 1)
```

This statement sets array element H(I, J) to the value 1.0/REAL(I + J - 1) for values of I and J between 1 and N.

Consider the following:

```
TYPE MONARCH
  INTEGER, POINTER :: P
END TYPE MONARCH
TYPE(MONARCH), DIMENSION(8) :: PATTERN
INTEGER, DIMENSION(8), TARGET :: OBJECT
FORALL(J=1:8) PATTERN(J)%P => OBJECT(1+IEOR(J-1,2))
```

This FORALL statement causes elements 1 through 8 of array PATTERN to point to elements 3, 4, 1, 2, 7, 8, 5, and 6, respectively, of OBJECT. IEOR can be referenced here because it is pure.

The following example shows a FORALL construct:

```
FORALL(I = 3:N + 1, J = 3:N + 1)
  C(I, J) = C(I, J + 2) + C(I, J - 2) + C(I + 2, J) + C(I - 2, J)
  D(I, J) = C(I, J)
END FORALL
```

The assignment to array D uses the values of C computed in the first statement in the construct, not the values before the construct began execution.

WHERE

FORMAT

Statement: *Specifies the form of data being transferred and the data conversion (editing) required to achieve that form.*

Syntax

FORMAT (*format-list*)

format-list	Is a list of one or more of the following edit descriptors, separated by commas or slashes (/):

Data edit descriptors:	I, B, O, Z, F, E, EN, ES, D, G, L, and A.
Control edit descriptors:	T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.
String edit descriptors:	H, 'c', and "c", where *c* is a character constant.

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Edit descriptors can be nested and a *repeat specification* can precede data edit descriptors, the slash edit descriptor, or a parenthesized list of edit descriptors.

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see the OPEN statement.

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $,+, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

Whenever an edit descriptor requires an integer constant, you can specify an expression enclosed in angle brackets (< and >). For more information, see Variable Format Expressions.

The integer expression can be any valid Fortran expression, including function calls and references to dummy arguments, with the following restrictions:

- Expressions cannot be used with the H edit descriptor.
- Expressions cannot contain graphical relational operators (such as > and <).

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement.

The following tables summarize the different kinds of edit descriptors:

Data Edit Descriptors

Code	Form [1]	Effect
A	A[w]	Transfers character or Hollerith values.
B	Bw[.m]	Transfers binary values.
D	Dw.d	Transfers real values with D exponents.
E	Ew.d[Ee]	Transfers real values with E exponents.
EN	ENw.d[Ee]	Transfers real values with engineering notation.
ES	ESw.d[Ee]	Transfers real values with scientific notation.
F	Fw.d	Transfers real values with no exponent.
G	Gw.d[Ee]	Transfers values of all intrinsic types.
I	Iw[.m]	Transfers decimal integer values.
L	Lw	Transfers logical values: on input, transfers characters; on output, transfers T or F.
O	Ow[.m]	Transfers octal values.
Z	Zw[.m]	Transfers hexadecimal values.

[1] *w* is the field width.

m is the minimum number of digits that must be in the field (including zeros).

d is the number of digits to the right of the decimal point.

E is the exponent field.

e is the number of digits in the exponent.

Control Edit Descriptors

Code	Form	Effect
BN	BN	Ignores embedded and trailing blanks in a numeric input field.
BZ	BZ	Treats embedded and trailing blanks in a numeric input field as zeros.

Code	Form	Effect
P	kP	Interprets certain real numbers with a specified scale factor.
Q	Q	Returns the number of characters remaining in an input record.
S	S	Reinvokes optional plus sign (+) in numeric output fields; counters the action of SP and SS.
SP	SP	Writes optional plus sign (+) into numeric output fields.
SS	SS	Suppresses optional plus sign (+) in numeric output fields.
T	Tn	Tabs to specified position.
TL	TLn	Tabs left the specified number of positions.
TR	TRn	Tabs right the specified number of positions.
X	nX	Skips the specified number of positions.
$	$	Suppresses trailing carriage return during interactive I/O.
:	:	Terminates format control if there are no more items in the I/O list.
/	[r]/	Terminates the current record and moves to the next record.
\	\	Continues the same record; same as $.

String Edit Descriptors

Code	Form	Effect
H	nHch[ch...]	Transfers characters following the H edit descriptor to an output record.
'c' [2]	'c'	Transfers the character literal constant (between the delimiters) to an output record.

[2] These delimiters can also be quotation marks (").

Example

```
INTEGER width, value
width = 2
read (*,1) width, value
```

```
!  if the input is 3123, prints 123, not 12
1  format ( i1, i<width>)
   print *, value
   END
```

FORM TEAM

Statement: *Defines team variables; creates one or more teams of images from the images on the current team.*

Syntax

The FORM TEAM statement takes the following form:

`FORM TEAM(`*`team-number, team-variable`* `[,` *`form-team-spec-list`*`])`

team-number	Is a scalar-integer-expression.
team-variable	Is a scalar variable of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV.
form-team-spec	NEW_INDEX = *scalar-integer-expression* or *sync-stat-list*
sync-stat-list	Is STAT= *stat-var* or ERRMSG = *err-var*
stat-var	Is a scalar integer variable in which the status of the FORM TEAM operation is stored.
err-var	Is a scalar default character variable in which explanatory text is stored if an error occurs.

The *form-team-spec* items can appear in any order. Each specifier in a FORM TEAM statement can appear at most once. *stat-var* and *err-var* cannot be coindexed variables.

Description

A FORM TEAM statement creates a new team for each unique *team-number* specified by the active images of the current team. The teams are identified by their team numbers, which are positive integers. An image becomes a member of the *team-number* specified on the FORM TEAM statement the image executes. The *team-variable* becomes defined with values that describe the team.

An image index must be positive and less than or equal to *n*, the number of images on the team. If NEW_INDEX= is specified, the value of the *scalar-integer-expression* is the image index the image executing the FORM TEAM statement will have on its new team. Its value must be different from any value specified for every other image that is assigned to the same new team. If NEW_IMAGE= is not specified, the image is given a processor-dependent unique image index in the range 1, 2, … n on the new team.

All active images of the current team must execute the same FORM TEAM statement. An implicit SYNC ALL occurs at the FORM TEAM statement. Execution of the segment following the FORM TEAM statement is delayed until other images of the current team have executed the same FORM TEAM statement the same number of times. FORM TEAM is an image control statement; all segments executed before the FORM TEAM statement precede all segments that execute after the FORM TEAM statement.

If STAT= appears and no error occurs, *stat-var* becomes defined with the value 0. If an image on the current team has executed a STOP statement, *stat-var* is assigned the value STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. If there is a failed image on the current team and no other error occurs, *stat-var* is assigned the value STAT_FAILED_IMAGE from ISO_FORTRAN_ENV. Otherwise, *stat-var* is assigned a positive integer value different from STAT_FAILED_IMAGE and STAT_STOPPED_IMAGE.

team-variable becomes undefined if an error condition occurs.

Examples

Example 1:

```
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)    :: one_or_two
IF (THIS_IMAGE() .LE. NUM_IMAGES() / 2) THEN
   new_team = 1
ELSE
   new_team = 2
END IF
FORM TEAM (new_team, one_or_two)
```

If the initial team has seven images, and the initial team executes the above FORM TEAM statement, two teams are formed. The new image indices are assigned by the runtime system in a processor-dependent manner.

Team number 1 has three images, images [1, 2, 3] of the initial team with new image indices [1, 2, 3]. Team number 2 has four images, images [4, 5, 6, 7] from the initial team, with new image indices [1, 2, 3, 4]. The team variable `one_or_two` on initial team images [1, 2, 3] collectively describe team number 1, while the team variable `one_or_two` on the initial team images [4, 5, 6, 7] collectively describe team number 2.

Example 2:

```
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)    :: odd_even
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
```

If a team with 10 images executes the above code, two teams are formed. Team number 1 contains the odd numbered images [1, 3, 5, 7, 9] of the parent team, and team number 2 contains the even numbered images [2, 4, 6, 8, 10] of the parent. New image indices on each team are assigned by the processor. The team variable `odd_even` across the odd numbered images on the parent team collectively describe team number 1, and the team variable `odd_even` across the even numbered images on the parent team collectively describe team number 2.

Example 3:

```
USE ISO_FORTRAN_ENV
INTEGER, PARAMETER       :: n = 4
TYPE (TEAM_TYPE)         :: column
REAL,CODIMENSION[n, *]   :: co_array
INTEGER,DIMENSION(2)     :: my_cosubscripts
my_cosubscripts (:)     = THIS_IMAGE(co_array)
FORM TEAM (my_cosubscripts(2), column, NEW_INDEX = my_cosubscripts(1))
```

If there are 16 images on the initial team, the scalar coarray `co_array` will be distributed across a 4x4 grid of processors. The image indices of the 4x4 grid are:

1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

THIS_IMAGE (co_array) will return a two element array of integer cosubscripts of `co_array` on the image that executes the reference to THIS_IMAGE. The cosubscripts of each image are:

1,1	1,2	1,3	1,4
2,1	2,2	2,3	2,4
3,1	3,2	3,3	3,4
4,1	4,2	4,3	4,4

Execution of the FORM TEAM statement divides the initial team into four teams of four images. Each team contains the images of one column of the grid of processors. The team number of each team is the column number in the processor grid, and the image indices on each new team are the row indices of the processor grid. The new image numbers on each team are shown below:

Team Number	1	2	3	4
	1	1	1	1
	2	2	2	2
	3	3	3	3
	4	4	4	4

Example 4:

This example divides a 4x4 grid of images into 4 2x2 grids of images. Team numbers are assigned in the FORM TEAM statement that reflect the position of each team in the grid of subteams. The example also shows the use of NEW_INDEX to assign image indices to the images of the new teams.

The image indices of the 4x4 grid are:

1	5	9	13
2	6	10	14
3	7	11	15
4	8	12	16

The 2x2 grids are laid out and identified symbolically and with team numbers as:

top_left (1,1)	top_right (1,2)
bot_left (2,1)	bot_right (2,2)

The image numbers on each of the teams in the 2x2 grids become:

1	3	1	3
2	4	2	4
1	3	1	3
2	4	2	4

```
   PROGRAM MAIN
   USE ISO_FORTRAN_ENV
   INTEGER,PARAMETER          :: top_left=11, bot_left=21, top_right=12, bot_right=22
   INTEGER,DIMENSION(16)      :: quads = [top_left,  top_left,  bot_left,  bot_left,         &
                                          top_left,  top_left,  bot_left_ bot_left,          &
                                          top_right, top_right, bot_right, bot_right,        &
                                          top_right, top_right, bot_right, bot_right]
   INTEGER,DIMENSION(16)      :: images         = [1,2,1,2,3,4,3,4,1,2,1,2,3,4,3,4]
   TYPE(TEAM_TYPE)            :: quadrants
   INTEGER                    :: me

   me = THIS_IMAGE()
```

```
    FORM TEAM (quads(me), quadrants, NEW_INDEX=images(me))
      . . .
    END PROGRAM
```

Example 5:

```
    USE ISO_FORTRAN_ENV
    TYPE (TEAM_TYPE) :: original
    FORM TEAM (1, original, NEW_INDEX = THIS_IMAGE())
```

This example forms a single subteam described by the team variable original. The subteam has the same number of images as the initial team, and each image has the same image number on the initial team as on the subteam. However, `original` describes a team that is different but functionally the same as the initial team. It has a parent team, while the initial team does not.

Using Coarrays

FP_CLASS

Elemental Intrinsic Function (Generic): *Returns the class of an IEEE* real (binary32, binary64, and binary128) argument. This function cannot be passed as an actual argument.*

Syntax

`result = FP_CLASS (x)`

x	(Input) Must be of type real.

Results

The result type is INTEGER(4). The return value is one of the following:

Class of Argument	Return Value
Signaling NaN	FOR_K_FP_SNAN
Quiet NaN	FOR_K_FP_QNAN
Positive Infinity	FOR_K_FP_POS_INF
Negative Infinity	FOR_K_FP_NEG_INF
Positive Normalized Number	FOR_K_FP_POS_NORM
Negative Normalized Number	FOR_K_FP_NEG_NORM
Positive Subnormal Number	FOR_K_FP_POS_DENORM
Negative Subnormal Number	FOR_K_FP_NEG_DENORM
Positive Zero	FOR_K_FP_POS_ZERO
Negative Zero	FOR_K_FP_NEG_ZERO

The preceding return values are defined in file `for_fpclass.for`.

Example

FP_CLASS (4.0_8) has the value 4 (FOR_K_FP_POS_NORM).

FPUTC

Portability Function: *Writes a character to the file specified by a Fortran external unit, bypassing normal Fortran input/output.*

Module

USE IFPORT

Syntax

`result = FPUTC (lunit,char)`

lunit	(Input) INTEGER(4). Unit number of a file.
char	(Output) Character*(*). Variable whose value is to be written to the file corresponding to *lunit*.

Results

The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

EINVAL - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with *lunit*, be sure to read Input and Output Routines in Overview of Portability Routines.

Example

```
use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit,file = 'fputc.dat')
do i = 1,26
  char1 = char(123-i)
  i4 = fputc(1,char1)        !make valid writes
  if (i4.ne.0) iflag = 1
enddo
rewind (1)
read (1,'(a)') string
print *, string
```

I/O Formatting

FRACTION

Elemental Intrinsic Function (Generic): *Returns the fractional part of the model representation of the argument value.*

Syntax

`result = FRACTION (x)`

x	(Input) Must be of type real.

Results

The result type and kind are the same as *x*.

The result has the value *x** b ^{e}. Parameters *b* and *e* are defined in Model for Real Data.

If *x* has the value zero, the result has the value zero.

Example

If 3.0 is a REAL(4) value, FRACTION (3.0) has the value 0.75.

The following shows another example:

```
REAL result
result = FRACTION(3.0) ! returns 0.75
result = FRACTION(1024.0) ! returns 0.5
```

FREE

Intrinsic Subroutine (Specific): *Frees a block of memory that is currently allocated. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL FREE (addr)
```

addr	(Input) Must be of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This value is the starting address of the memory block to be freed, previously allocated by MALLOC.

If the freed address was not previously allocated by MALLOC, or if an address is freed more than once, results are unpredictable.

Example

```
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE)     ! ADDR will point to STORAGE
SIZE = 1024                 ! Size in bytes
ADDR = MALLOC(SIZE)         ! Allocate the memory
CALL FREE(ADDR)             ! Free it
```

FREEFORM and NOFREEFORM

General Compiler Directives: *FREEFORM specifies that source code is in free-form format. NOFREEFORM specifies that source code is in fixed-form format.*

Syntax

```
!DIR$ FREEFORM
```

```
!DIR$ NOFREEFORM
```

When the FREEFORM or NOFREEFORM directives are used, they remain in effect for the remainder of the source or include file in which the directive appears, or until the opposite directive is used. When in effect, they apply to include files, but do not affect USE modules, which are compiled separately.

source or include file in which the directive appears

Example

Consider the following:

```
      SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
! is in column 1 and fixed form
!     X is in column 7
      REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ FREEFORM          ! what follows is freeform
  !DIR$ ASSUME (MOD(NX,8) .EQ. 0)
  ! ensure that the first array access in the loop is aligned
  !DIR$ ASSUME (MOD(I1,8) .EQ. 1)
    DO J=J1,J2
      DO I=I1,I2
        A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
      ENDDO
    ENDDO
  !DIR$ NOFREEFORM            ! and now back to fixed form
       END SUBROUTINE F
```

FSEEK

Portability Function: *Repositions a file specified by a Fortran external unit.*

Module

USE IFPORT

Syntax

`result = FSEEK (`*`lunit`*`,`*`offset`*`,`*`from`*`)`

lunit	(Input) INTEGER(4). External unit number of a file.
offset	(Input) INTEGER(4) or INTEGER(8). Offset in bytes, relative to *from*, that is to be the new location of the file marker.
from	(Input) INTEGER(4). A position in the file. It must be one of the following:

Value	Variable	Position
0	SEEK_SET	Positions the file relative to the beginning of the file.
1	SEEK_CUR	Positions the file relative to the current position.
2	SEEK_END	Positions the file relative to the end of the file.

Results

The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:

EINVAL: The specified unit is invalid because either the unit is not already open, an invalid unit number was specified, or the *from* parameter is invalid.

The file specified in *lunit* must be open.

Example

```
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1,file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1,offset,ipos)
if (.NOT. stat) then
  istat=fgetc(1,ichar)
  print *, 'data is ',ichar
end if
```

FSTAT

Portability Function: *Returns detailed information about a file specified by a external unit number.*

Module

USE IFPORT

Syntax

```
result = FSTAT (lunit,statb)
```

lunit (Input) INTEGER(4). External unit number of the file to examine.

statb (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of *statb* contain the following values:

Element	Description	Values or Notes
statb(1)	Device the file resides on	Windows: Always 0 Linux: System dependent
statb(2)	File inode number	Windows: Always 0 Linux: System dependent
statb(3)	Access mode of the file	See the table in Results
statb(4)	Number of hard links to the file	Windows: Always 1 Linux: System dependent
statb(5)	User ID of owner	Windows: Always 1 Linux: System dependent
statb(6)	Group ID of owner	Windows: Always 1 Linux: System dependent
statb(7)	Raw device the file resides on	Windows: Always 0 Linux: System dependent
statb(8)	Size of the file	
statb(9)	Time when the file was last accessed[1]	Windows: Only available on non-FAT file systems; undefined on FAT systems Linux: System dependent
statb(10)	Time when the file was last modified[1]	
statb(11)	Time of last file status change[1]	Windows: Same as stat(10) Linux: System dependent
statb(12)	Blocksize for file system I/O operations	Windows: Always 1 Linux: System dependent

Element	Description	Values or Notes
[1]Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).		

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINVAL (*lunit* is not a valid unit number, or is not open).

The access mode (the third element of *statb*) is a bitmap consisting of an IOR of the following constants:

Symbolic name	Constant	Description	Notes
S_IFMT	O'0170000'	Type of file	
S_IFDIR	O'0040000'	Directory	
S_IFCHR	O'0020000'	Character special	Never set on Windows* systems
S_IFBLK	O'0060000'	Block special	Never set on Windows systems
S_IFREG	O'0100000'	Regular	
S_IFLNK	O'0120000'	Symbolic link	Never set on Windows systems
S_IFSOCK	O'0140000'	Socket	Never set on Windows systems
S_ISUID	O'0004000'	Set user ID on execution	Never set on Windows systems
S_ISGID	O'0002000'	Set group ID on execution	Never set on Windows systems
S_ISVTX	O'0001000'	Save swapped text	Never set on Windows systems
S_IRWXU	O'0000700'	Owner's file permissions	
S_IRUSR, S_IREAD	O'0000400'	Owner's read permission	Always true on Windows systems
S_IWUSR, S_IWRITE	O'0000200'	Owner's write permission	
S_IXUSR, S_IEXEC	O'0000100'	Owner's execute permission	Based on file extension (.EXE, .COM, .CMD, or .BAT)
S_IRWXG	O'0000070'	Group's file permissions	Same as S_IRWXU on Windows systems
S_IRGRP	O'0000040'	Group's read permission	Same as S_IRUSR on Windows systems

Symbolic name	Constant	Description	Notes
S_IWGRP	O'0000020'	Group's write permission	Same as S_IWUSR on Windows systems
S_IXGRP	O'0000010'	Group's execute permission	Same as S_IXUSR on Windows systems
S_IRWXO	O'0000007'	Other's file permissions	Same as S_IRWXU on Windows systems
S_IROTH	O'0000004'	Other's read permission	Same as S_IRUSR on Windows systems
S_IWOTH	O'0000002'	Other's write permission	Same as S_IWUSR on Windows systems
S_IXOTH	O'0000001'	Other's execute permission	Same as S_IXUSR on Windows systems

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

Example

```
USE IFPORT
integer(4) statarray(12), istat
OPEN (unit=1,file='datfile.dat')
ISTAT = FSTAT (1, statarray)
if (.NOT. istat) then
    print *, statarray
end if
```

INQUIRE
STAT

FTELL, FTELLI8

Portability Functions: *Return the current position of a file.*

Module

USE IFPORT

Syntax

`result = FTELL (lunit)`

`result = FTELLI8 (lunit)`

lunit (Input) INTEGER(4). External unit number of a file.

Results

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

EINVAL: *lunit* is not a valid unit number, or is not open.

FULLPATHQQ

Portability Function: *Returns the full path for a specified file or directory.*

Module

USE IFPORT

Syntax

`result = FULLPATHQQ (name,pathbuf)`

name	(Input) Character*(*). Item for which you want the full path. Can be the name of a file in the current directory, a relative directory or file name, or a network uniform naming convention (UNC) path.
pathbuf	(Output) Character*(*). Buffer to receive full path of the item specified in *name*.

Results

The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails. This function does not verify that the resulting path and file name are valid nor that they exist.

The length of the full path depends upon how deeply the directories are nested on the drive you are using. If the full path is longer than the character buffer provided to return it (*pathbuf*), FULLPATHQQ returns only that portion of the path that fits into the buffer.

Check the length of the path before using the string returned in *pathbuf*. If the longest full path you are likely to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the largest possible path buffer with the following statements:

```
USE IFPORT
CHARACTER($MAXPATH) pathbuf
```

$MAXPATH is a symbolic constant defined in `IFPORT.F90` as 260.

Example

```
    USE IFPORT
    USE IFCORE
    CHARACTER($MAXPATH) buf
    CHARACTER(3)        drive
    CHARACTER(256)      dir
    CHARACTER(256)      name
    CHARACTER(256)      ext
    CHARACTER(256)      file
    INTEGER(4)          len
    DO WHILE (.TRUE.)
      WRITE (*,*)
      WRITE (*,'(A, \)') ' Enter filename (Hit &
                          RETURN to exit): '
      len = GETSTRQQ(file)
      IF (len .EQ. 0) EXIT
      len = FULLPATHQQ(file, buf)
      IF (len .GT. 0) THEN
        WRITE (*,*) buf(:len)
      ELSE
        WRITE (*,*) 'Can''t get full path'
        EXIT
      END IF
```

```
!
!      Split path
       WRITE (*,*)
       len = SPLITPATHQQ(buf, drive, dir, name, ext)
       IF (len .NE. 0) THEN
         WRITE (*, 900) ' Drive: ', drive
         WRITE (*, 900) ' Directory: ', dir(1:len)
         WRITE (*, 900) ' Name: ', name
         WRITE (*, 900) ' Extension: ', ext
       ELSE
         WRITE (*, *) 'Can''t split path'
       END IF
     END DO
900  FORMAT (A, A)
     END
```

See Also

SPLITPATHQQ

FUNCTION

Statement: *The initial statement of a function subprogram. A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression.*

Syntax

[*prefix* [*prefix*]] FUNCTION *name* [([*d-arg-list*])] [*suffix*]

   [*specification-part*]

   [*execution-part*]

[CONTAINS

   [*internal-subprogram-part*]]

END [FUNCTION [*name*]]

prefix

(Optional) Is any of the following:

- A data type specifier
- ELEMENTAL

  Acts on one array element at a time. This is a restricted form of a procedure.
- IMPURE

  Asserts that the procedure has side effects.
- MODULE

  Indicates a separate module procedure. See separate module procedures.
- NON_RECURSIVE

  Indicates the function is not recursive.
- PURE

  Asserts that the procedure has no side effects.
- RECURSIVE

Permits direct and indirect recursion to occur. If a function is directly recursive and array valued, and RESULT is not specified, any reference to the function name in the executable part of the function is a reference to the function result variable.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if *lang-binding* is specified in *suffix*.

name

Is the name of the function. If RESULT is specified, the function name must not appear in any specification statement in the scoping unit of the function subprogram.

The function name can be followed by the length of the data type. The length is specified by an asterisk (*) followed by any unsigned, nonzero integer that is a valid length for the function's type. For example, REAL FUNCTION LGFUNC*8 (Y, Z) specifies the function result as REAL(8) (or REAL*8).

This optional length specification is not permitted if the length has already been specified following the keyword CHARACTER.

d-arg-list

(Optional) Is a list of one or more dummy arguments.

If there are no dummy arguments, no suffix, and no RESULT variable, the parentheses can be omitted. For example, the following is valid:

```
FUNCTION F
```

suffix

(Optional) Takes one of the following forms:

[RESULT (*r-name*)] *lang-binding*

lang-binding [RESULT (*r-name*)]

r-name

(Optional) Is the name of the function result. This name must not be the same as the function name.

lang-binding

Takes the following form:

BIND (C [, NAME=*ext-name*])

ext-name

Is a character scalar constant expression that can be used to construct the external name.

specification-part

Is one or more specification statements.

execution-part

Is one or more executable constructs or statements.

internal-subprogram-part

Is one or more internal subprograms (defining internal procedures). The *internal-subprogram-part* is preceded by a CONTAINS statement.

Description

The type and kind parameters (if any) of the function's result can be defined in the FUNCTION statement or in a type declaration statement within the function subprogram, but not both. If no type is specified, the type is determined by implicit typing rules in effect for the function subprogram.

Execution begins with the first executable construct or statement following the FUNCTION statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

If you specify CHARACTER(LEN=*) as the type of the function, the function assumes the length declared for it in the program unit that invokes it. This type of the resulting character function can have different lengths when it is invoked by different program units. An assumed-length character function cannot be directly recursive. Assumed-length character functions are an obsolescent feature in the Fortran standard.

If the character length is specified as an integer constant, the value must agree with the length of the function specified in the program unit that invokes the function. If no length is specified, a length of 1 is assumed.

If the function is array-valued, allocatable, or a pointer, the declarations within the function must state these attributes for the function result name. The specification of the function result attributes, dummy argument attributes, and the information in the procedure heading collectively define the interface of the function.

The value of the result variable is returned by the function when it completes execution. Certain rules apply depending on whether the result is a pointer, as follows:

- If the result is a pointer, its allocation status must be determined before the function completes execution. The function must associate a target with the pointer, or cause the pointer to be explicitly disassociated from a target.

  If the pointer result points to a TARGET with the INTENT(IN) attribute, the function can give the result a value but the caller is not allowed to change the value pointed to.
- The shape of the value returned by the function is determined by the shape of the result variable when the function completes execution.
- If the result is not a pointer, its value must be defined before the function completes execution. If the result is an array, all the elements must be defined. If the result is a derived-type structure, all the components must be defined.

A function subprogram *cannot* contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A function can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

Example

The following example uses the Newton-Raphson iteration method `(F(X) = cosh(X) + cos(X) - A = 0)` to get the root of the function:

```
FUNCTION ROOT(A)
  IF (A >= 2.0) THEN
    X  = 1.0
    DO
      EX = EXP(X)
      EMINX = 1./EX
      ROOT  = X - ((EX+EMINX)*.5+COS(X)-A)/((EX-EMINX)*.5-SIN(X))
      IF (ABS((X-ROOT)/ROOT) .LT. 1E-6) RETURN
      X  = ROOT
    END DO
  ELSE
```

```
      STOP 'in FUNCTION ROOT, A must be >= 2.0'
    ENDIF
  END
```

In the preceding example, the following formula is calculated repeatedly until the difference between X_i and X_{i+1} is less than 1.0E-6:

$$X_{i+1} = X_i - \frac{\cos(X_i) + \cos(X_i) - A}{\sinh(X_i) - \sin(X_i)}$$

The following example shows an assumed-length character function:

```
CHARACTER*(*) FUNCTION REDO(CARG)
  CHARACTER*1 CARG
  DO I=1,LEN(REDO)
    REDO(I:I) = CARG
  END DO
  RETURN
END FUNCTION
```

This function returns the value of its argument, repeated to fill the length of the function.

Within any given program unit, all references to an assumed-length character function must have the same length. In the following example, the REDO function has a length of 1000:

```
CHARACTER*1000 REDO, MANYAS, MANYZS
MANYAS = REDO('A')
MANYZS = REDO('Z')
```

Another program unit within the executable program can specify a different length. For example, the following REDO function has a length of 2:

```
CHARACTER HOLD*6, REDO*2
HOLD = REDO('A')//REDO('B')//REDO('C')
```

The following example shows a dynamic array-valued function:

```
FUNCTION SUB (N)
  REAL, DIMENSION(N) :: SUB
  ...
END FUNCTION
```

The following shows another example:

```
      INTEGER Divby2
10    PRINT *, 'Enter a number'
      READ *, i
      Print *, Divby2(i)
      GOTO 10
      END
C
C     This is the function definition
C
      INTEGER FUNCTION Divby2 (num)
      Divby2=num / 2
      END FUNCTION
```

The following example shows an allocatable function with allocatable arguments:

```
MODULE AP
CONTAINS

 FUNCTION ADD_VEC(P1,P2)
  ! Function to add two allocatable arrays of possibly differing lengths.
  ! The arrays may be thought of as polynomials (coefficients)
   REAL, ALLOCATABLE :: ADD_VEC(:), P1(:), P2(:)

  ! This function returns an allocatable array whose length is set to
  ! the length of the larger input array.
  ALLOCATE(ADD_VEC(MAX(SIZE(P1), SIZE(P2))))
  M = MIN(SIZE(P1), SIZE(P2))
  ! Add up to the shorter input array size
  ADD_VEC(:M) = P1(:M) + P2(:M)
  ! Use the larger input array elements afterwards (from P1 or P2)
  IF(SIZE(P1) > M) THEN
    ADD_VEC(M+1:) = P1(M+1:)
  ELSE IF(SIZE(P2) > M) THEN
    ADD_VEC(M+1:) = P2(M+1:)
  ENDIF
 END FUNCTION
END MODULE

PROGRAM TEST
 USE AP
 REAL, ALLOCATABLE :: P(:), Q(:), R(:), S(:)
 ALLOCATE(P(3))
 ALLOCATE(Q(2))
 ALLOCATE(R(3))
 ALLOCATE(S(3))

 ! Notice that P and Q differ in length
 P = (/4,2,1/)  ! P = X**2 + 2X + 4
 Q = (/-1,1/)   ! Q =         X - 1
 PRINT *,' Result should be:    3.000000       3.000000       1.000000'
 PRINT *,' Coefficients are: ', ADD_VEC(P, Q)  ! X**2 + 3X + 3

 P = (/1,1,1/)  ! P =  X**2 +  X + 1
 R = (/2,2,2/)  ! R = 2X**2 + 2X + 2
 S = (/3,3,3/)  ! S = 3X**2 + 3X + 3
 PRINT *,' Result should be:    6.000000       6.000000       6.000000'
 PRINT *,' Coefficients are: ', ADD_VEC(ADD_VEC(P,R), S)
END
```

Consider the following example:

```
module mymodule
type :: vec
  integer :: x(3)
contains
  procedure :: at
end type vec

contains
  function at( this, i ) result( p )
    implicit none
    class(vec), intent(in), target :: this
    integer, intent(in) :: i
```

```
    integer, pointer :: p

    p => this%x(i)
  end function at
end module mymodule

program test
use mymodule
implicit none
type(vec) :: myvec

myvec%x =  [1,2,3]

! pointer returned by function at gives the correct values: 1, 2, and 3
write(6,*) myvec%at(1), myvec%at(2), myvec%at(3)

! changing any array element is an error
myvec%at(1) = 4
myvec%at(2) = 5
myvec%at(3) = 6
…
end program test
```

G

This section describes language features that start with G.

G

GAMMA

Elemental Intrinsic Function (Generic): *Returns the gamma value of its argument.*

Syntax

`result = GAMMA (x)`

x	(Input) Must be of type real. It must not be zero or a negative number.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the gamma function of x,

$$\Gamma(X) = \begin{cases} \int_0^\infty t^{X-1} \exp(-t)\, dt & X > 0 \\ \int_0^\infty t^{X-1} (\exp(-t) - \sum_{k=0}^{n} \frac{(-t)^k}{k!})\, dt & -n-1 < X < -n,\ n \text{ an integer} \geq 0 \end{cases}$$

Example

GAMMA (1.0) has the approximate value 1.000.

GENERIC

Statement: *Declares a generic interface that is bound to a derived type-bound procedure, or specifies a generic identifier for one or more specific procedures.*

Syntax

The GENERIC statement takes the following form:

```
GENERIC [, access-spec]:: generic-spec => binding-name1 [, binding-name2]...
```

access-spec

(Optional) Is the PUBLIC or PRIVATE attribute. Only one can be specified. *access-spec* specifies the accessibility of *generic-spec*. *access-spec* can only appear in the specification part of a module.

generic-spec

Is an explicit INTERFACE statement using one of the following:

- generic-name

  generic-spec can be the name of a previously declared accessible generic name, in which case this statement extends that interface. For more information, see Defining Generic Names for Procedures.
- OPERATOR (*op*)

  op is an intrinsic or a user-defined operator. For more information, see Defining Generic Operators.
- ASSIGNMENT (=)

  See Defining Generic Assignment.
- *defined-io-spec*, which is one of the following:
  - READ (FORMATTED)
  - READ (UNFORMATTED)
  - WRITE (FORMATTED)
  - WRITE (UNFORMATTED)

  See Defined I/O Procedures.

The same *generic-spec* can be used in several generic bindings. In this case, every occurrence of the same *generic-spec* must have the same accessibility.

binding-spec1 [, binding-spec2,...]

Is the name of a specific procedure. It cannot be the name of a specific procedure that has been specified in an accessible generic interface with the same generic identifier. At most one of the specific names can be the same as the generic name.

Examples

Consider the following:

```
GENERIC :: GEN_FUNC => INT_FUNC, REAL_FUNC
GENERIC :: GEN_FUNC => CMPLX_FUNC
```

If INT_FUNC, REAL_FUNC, and CMPLX_FUNC are all functions with accessible interfaces, the first GENERIC statement declares GEN_FUNC to be a generic function name that can resolve to INT_FUNC or REAL_FUNC. The second GENERIC statement extends GEN_FUNC to be resolvable to a third specific function, CMPLX_FUNC.

Consider the following:

```
TYPE MY_TYPE2
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC1
  PROCEDURE,PASS(C) :: UPROC => UPROC1
  GENERIC :: OPERATOR(+) => MYPROC, UPROC
END TYPE MY_TYPE2
...
TYPE,EXTENDS(MY_TYPE2) :: MY_TYPE3
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC2
  PROCEDURE,PASS(C) :: UPROC => UPROC2
END TYPE MY_TYPE3
```

The type MY_TYPE3 inherits the generic operator '+'. Invoking the generic (+) invokes the specific type-bound procedure. For entities of type MY_TYPE3, that invokes the overriding actual procedure (MYPROC2 or UPROC2).

Consider the following:

```
TYPE MY_TYPE4
...
CONTAINS
  PROCEDURE :: FMTREAD   => MY_TYPE4_FMTREAD
  PROCEDURE :: FMTWRITE  => MY_TYPE4_FMTWRITE
  GENERIC   :: READ  (FORMATTED) => FMTREAD
  GENERIC   :: WRITE (FORMATTED) => FMTWRITE
END TYPE MY_TYPE4
```

When an object of type MY_TYPE4 appears in an I/O list and is associated with a DT format edit descriptor in a formatted READ statement, MY_TYPE4_FMTREAD is called to perform the read of the object. In a formatted WRITE, MY_TYPE4_FMTWRITE is called to perform the output of the object.

Defining Generic Names for Procedures

GERROR

Runtime Subroutine: *Returns a message for the last error detected by a Fortran runtime routine.*

Module

USE IFCORE

Syntax

CALL GERROR (*string*)

string	(Output) Character*(*). Message corresponding to the last detected error.

The last detected error does not necessarily correspond to the most recent function call. The compiler resets *string* only when another error occurs.

Example

```
USE IFCORE
character*40 errtext
character char1
integer*4 iflag, i4
. . .!Open unit 1 here
i4=fgetc(1,char1)
if (i4) then
  iflag = 1
  Call GERROR (errtext)
  print *, errtext
end if
```

PERROR
IERRNO

GETARG

Intrinsic Subroutine: *Returns the specified command-line argument (where the command itself is argument number zero). Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

CALL GETARG (*n*,*buffer*[,*status*])

n	(Input) Must be a scalar of type integer. This value is the position of the command-line argument to retrieve. The command itself is argument number 0.
buffer	(Output) Must be a scalar of type default character. Its value is the returned command-line argument.
status	(Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. If there were no errors, *status* returns the number of characters in the retrieved command-line argument before truncation or blank-padding. (That is, *status* is the original number of characters in the command-line argument.) Errors return a value of -1. Errors include specifying an argument position less than 0 or greater than the value returned by IARGC.

GETARG returns the *n*th command-line argument. If *n* is zero, the name of the executing program file is returned.

GETARG returns command-line arguments as they were entered. There is no case conversion.

If the command-line argument is shorter than *buffer*, GETARG pads *buffer* on the right with blanks. If the argument is longer than *buffer*, GETARG truncates the argument on the right. If there is an error, GETARG fills *buffer* with blanks.

Example

Assume a command-line invocation of `PROG1 -g -c -a`, and that *buffer* is at least five characters long. The following calls to GETARG return the corresponding arguments in *buffer* and *status*:

Statement	String returned in *buffer*	Length returned in *status*
CALL GETARG (0, buffer, status)	PROG1	5
CALL GETARG (1, buffer)	-g	undefined
CALL GETARG (2, buffer, status)	-c	2
CALL GETARG (3, buffer)	-a	undefined
CALL GETARG (4, buffer, status)	all blanks	-1

GET_COMMAND_ARGUMENT

GETC

Portability Function: *Reads the next available character from external unit 5, which is normally connected to the console.*

Module

USE IFPORT

Syntax

`result = GETC (char)`

char — (Output) Character*(*). First character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

Results

The result type is INTEGER(4). The result is zero if successful, or -1 if an end-of-file was detected.

Example

```
   use IFPORT
   character ans,errtxt*40
   print *, 'Enter a character: '
   ISTAT = GETC (ans)
if (istat) then
   call gerror(errtxt)
end if
```

See Also

GETCHARQQ
GETSTRQQ

GETCHARQQ

Runtime Function: *Returns the next keystroke.*

Module

USE IFCORE

Syntax

```
result = GETCHARQQ( )
```

Results

The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character. If the key pressed is a function or direction key, a hex Z'00' or Z'E0' is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.

If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn't there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQQ in your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application. The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQQ.

Example

```
!  Program to demonstrate GETCHARQQ
USE IFCORE
CHARACTER(1) key / 'A' /
PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)
WRITE (*,*) ' Type a key: (or q to quit)'
!  Read keys until ESC or q is pressed
DO WHILE (ICHAR (key) .NE. ESC)
   key = GETCHARQQ()
!  Some extended keys have no ASCII representation
   IF(ICHAR(key) .EQ. NOREP) THEN
     key = GETCHARQQ()
     WRITE (*, 900) 'Not ASCII. Char = NA'
     WRITE (*,*)
!  Otherwise, there is only one key
   ELSE
     WRITE (*,900) 'ASCII. Char = '
     WRITE (*,901) key
   END IF
   IF (key .EQ. 'q' ) THEN
     EXIT
   END IF
   END DO
```

```
900   FORMAT (1X, A, \)
901   FORMAT (A)
END
```

GET_COMMAND

Intrinsic Subroutine: *Returns the entire command that was used to invoke the program.*

Syntax

`CALL GET_COMMAND ([command, length, status, errmsg])`

command	(Output; optional) Must be a scalar of type default character. If specified, its value is the entire command that was used to invoke the program. If the command cannot be determined, its value is all blanks.
length	(Output; optional) Must be a scalar of type integer. If specified, its value is the significant length of the command that was used to invoke the program. This length includes trailing blanks, but it does not include any truncation or padding used in the command. If the command length cannot be determined, its value is zero.
status	(Output; optional) Must be a scalar of type integer. If specified, its value is -1 if the command argument is present and has a length less than the significant length of the command. If the command cannot be retrieved, its value is positive; otherwise, it is assigned the value zero.
errmsg	(Input; output; optional) Must be a scalar of type default character. If an error occurs, it is assigned a processor-dependent explanatory message; otherwise, it is unchanged.

Example

See the example in COMMAND_ARGUMENT_COUNT.

See Also

GETARG
NARGS
IARGC
COMMAND_ARGUMENT_COUNT
GET_COMMAND_ARGUMENT

GET_COMMAND_ARGUMENT

Intrinsic Subroutine: *Returns a command line argument of the command that invoked the program. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL GET_COMMAND_ARGUMENT (number [, value, length, status, errmsg])
```

number	(Input) Must be a scalar of type integer. It must be non-negative and less than or equal to the value returned by the COMMAND_ARGUMENT_COUNT function. Its value is the position of the command-line argument to retrieve. The command itself is argument number zero.
value	(Output; optional) Must be a scalar of type default character. If specified, its value is the returned command-line argument or all blanks if the value is unknown.
length	(Output; optional) Must be a scalar of type integer. If specified, its value is the length of the returned command-line argument or zero if the length of the argument is unknown. This length includes significant trailing blanks. It does not include any truncation or padding that occurs when the argument is assigned to the *value* argument.
status	(Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. It is assigned the value -1 if the value argument is present and has a length less than the significant length of the command argument specified by *number*. It is assigned a processor-dependent positive value if the argument retrieval fails. Otherwise, it is assigned the value zero.
errmsg	(Input; output; optional) Must be a scalar of type default character. If an error occurs, it is assigned a processor-dependent explanatory message; otherwise, it is unchanged.

GET_COMMAND_ARGUMENT returns command-line arguments as they were entered. There is no case conversion.

Example

See the example in COMMAND_ARGUMENT_COUNT.

GETCONTROLFPQQ

Portability Subroutine: *Returns the floating-point processor control word.*

Module

USE IFPORT

Syntax

CALL GETCONTROLFPQQ (*controlword*)

controlword

(Output) INTEGER(2). Floating-point processor control word.

The floating-point control word is a bit flag that controls various modes of the floating-point processor.

The control word can be any of the following constants (defined in IFPORT.F90):

Parameter name	Hex value	Description
FPCW$MCW_IC	Z'1000'	**Infinity control mask**
FPCW$AFFINE	Z'1000'	Affine infinity
FPCW$PROJECTIVE	Z'0000'	Projective infinity
FPCW$MCW_PC	Z'0300'	**Precision control mask**
FPCW$64	Z'0300'	64-bit precision
FPCW$53	Z'0200'	53-bit precision
FPCW$24	Z'0000'	24-bit precision
FPCW$MCW_RC	Z'0C00'	**Rounding control mask**
FPCW$CHOP	Z'0C00'	Truncate
FPCW$UP	Z'0800'	Round up
FPCW$DOWN	Z'0400'	Round down
FPCW$NEAR	Z'0000'	Round to nearest
FPCW$MCW_EM	Z'003F'	**Exception mask**
FPCW$INVALID	Z'0001'	Allow invalid numbers
FPCW$DENORMAL	Z'0002'	Allow subnormals (very small numbers)
FPCW$SUBNORMAL	Z'0002'	Allow subnormals (very small numbers)
FPCW$ZERODIVIDE	Z'0004'	Allow divide by zero
FPCW$OVERFLOW	Z'0008'	Allow overflow
FPCW$UNDERFLOW	Z'0010'	Allow underflow
FPCW$INEXACT	Z'0020'	Allow inexact precision

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be disabled by setting the control bits to 1 with SETCONTROLFPQQ.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues.

You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause runtime errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings.

Example

```
USE IFPORT
INTEGER(2) control
CALL GETCONTROLFPQQ (control)
     ! if not rounding down
IF (IAND(control, FPCW$DOWN) .NE. FPCW$DOWN) THEN
  control = IAND(control, NOT(FPCW$MCW_RC)) ! clear all
                                            !  rounding
  control = IOR(control, FPCW$DOWN)         !  set to
                                            !  round down
  CALL SETCONTROLFPQQ(control)
END IF
END
```

See Also

SETCONTROLFPQQ
GETSTATUSFPQQ
SIGNALQQ
CLEARSTATUSFPQQ

GETCWD

Portability Function: *Returns the path of the current working directory.*

Module

USE IFPORT

Syntax

`result = GETCWD (dirname)`

dirname	(Output) Character *(*). Name of the current working directory path, including drive letter.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Example

```
    USE IFPORT
    character*30 dirname
!   variable dirname must be long enough to hold entire string
```

```
    integer(4) istat
    ISTAT = GETCWD (dirname)
    IF (ISTAT == 0) write *, 'Current directory is ',dirname
```

See Also

GETDRIVEDIRQQ

GETDAT

Portability Subroutine: *Returns the date.*

Module

USE IFPORT

Syntax

CALL GETDAT (*iyr*, *imon*, *iday*)

iyr	(Output) INTEGER(4) or INTEGER(2). Year (*xxxx*AD).
imon	(Output) INTEGER(4) or INTEGER(2). Month (1-12).
iday	(Output) INTEGER(4) or INTEGER(2). Day of the month (1-31).
	This subroutine is thread-safe.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example

```
! Program to demonstrate GETDAT and GETTIM
USE IFPORT
INTEGER(4) tmpday, tmpmonth, tmpyear
INTEGER(4) tmphour, tmpminute, tmpsecond, tmphund
CHARACTER(1) mer
CALL GETDAT(tmpyear, tmpmonth, tmpday)
CALL GETTIM(tmphour, tmpminute, tmpsecond, tmphund)
IF (tmphour .GT. 12) THEN
  mer = 'p'
  tmphour = tmphour - 12
ELSE
  mer = 'a'
END IF
WRITE (*, 900) tmpmonth, tmpday, tmpyear
900  FORMAT(I2, '/', I2.2, '/', I4.4)
WRITE (*, 901) tmphour, tmpminute, tmpsecond, tmphund, mer
901  FORMAT(I2, ':', I2.2, ':', I2.2, ':', I2.2, ' ',&
            A, 'm')
END
```

See Also

JDATE

GETDRIVEDIRQQ

Portability Function: *Returns the path of the current working directory on a specified drive.*

Module

USE IFPORT

Syntax

`result = GETDRIVEDIRQQ (drivedir)`

drivedir	(Input; output) Character*(*). On input, the drive whose current working directory path is to be returned. On output, the string containing the current directory on that drive in the form d:\dir.

Results

The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory on the specified drive. Zero is returned if the path is longer than the size of the character buffer *drivedir*.

You specify the drive from which to return the current working directory by putting the drive letter into *drivedir* before calling GETDRIVEDIRQQ. To make sure you get information about the current drive, put the symbolic constant FILE$CURDRIVE (defined in `IFPORT.F90`) into *drivedir*.

Because drives are identified by a single alphabetic character, GETDRIVEDIRQQ examines only the first letter of *drivedir*. For instance, if *drivedir* contains the path `c:\fps90\bin`, GETDRIVEDIRQQ (*drivedir*) returns the current working directory on drive C and disregards the rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive specified in *drivedir*. If the full path is longer than the length of *drivedir*, GETDRIVEDIRQQ returns only the portion of the path that fits into *drivedir*. If you are likely to encounter a long path, allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* systems, the function gets a path only when symbolic constant FILE$CURDRIVE has been applied to *drivedir*.

Example

```
!  Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
!  Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length .GT. 0) THEN
  WRITE (*,*) 'Current directory is: '
  WRITE (*,*) dir
ELSE
```

```
  WRITE (*,*) 'Failed to get current directory'
END IF
END
```

GETDRIVESIZEQQ

Portability Function: *Returns the total size of the specified drive and space available on it.*

Module

USE IFPORT

Syntax

`result = GETDRIVESIZEQQ (drive,total,avail)`

drive	(Input) Character*(*). String containing the letter of the drive to get information about.
total	(Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Total number of bytes on the drive.
avail	(Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Number of bytes of available space on the drive.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The data types and dimension (if any) specified for the *total* and *avail* arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of *drive*. The drive letter can be uppercase or lowercase. You can use the constant FILE$CURDRIVE (defined in `IFPORT.F90`) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

Example

```
! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
```

```
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A, A)') ' Drives available: ', drives
!
!Cycle through them for free space and write to console
DO i = 1, 26
  adrive = drives(i:i)
  status = .FALSE.
  WRITE (*,'(A, A, A, \)') ' Drive ', CHAR(i + 64), ':'
  IF (adrive .NE. ' ') THEN
     status = GETDRIVESIZEQQ(adrive, total, avail)
  END IF
  IF (status) THEN
     WRITE (*,*) avail, ' of ', total, ' bytes free.'
  ELSE
     WRITE (*,*) 'Not available'
  END IF
END DO
END
```

GETDRIVESQQ

Portability Function: *Reports which drives are available to the system.*

Module

USE IFPORT

Syntax

```
result = GETDRIVESQQ( )
```

Results

The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.

The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A CD' is returned.

On Linux* systems, the function returns a string filled with spaces.

Example

See the example for GETDRIVESIZEQQ.

GETENV

Portability Subroutine: *Returns the value of an environment variable.*

Module

USE IFPORT

Syntax

CALL GETENV (*ename*,*evalue*)

ename	(Input) Character*(*). Environment variable to search for.
evalue	(Output) Character*(*). Value found for *ename*. Blank if *ename* is not found.

Example

```
use IFPORT
character*40 libname
CALL GETENV ("LIB",libname)
TYPE *, "The LIB variable points to ",libname
```

See Also

GETENVQQ

GET_ENVIRONMENT_VARIABLE

Intrinsic Subroutine: *Gets the value of an environment variable.*

Syntax

CALL GET_ENVIRONMENT_VARIABLE (*name* [, *value*, *length*, *status*, *trim_name*, *errmsg*])

name	(Input) Must be a scalar of type default character. It is the name of the environment variable.
value	(Output; optional) Must be a scalar of type default character. If specified, it is assigned the value of the environment variable specified by *name*. If the environment variable does not exist, *value* is assigned all blanks.
length	(Output; optional) Must be a scalar of type integer. If specified, its value is the length of the environment variable, if it exists; otherwise, *length* is set to 0.
status	(Output; optional) Must be a scalar of type integer. If specified, it is assigned a value of 0 if the environment variable exists and either has no value or its value is successfully assigned to *value*. It is assigned a value of -1 if the *value* argument is present and has a length less than the significant length of the environment variable value. It is assigned a value of 1 if the environment variable does not exist. For other error conditions, it is assigned a processor-dependent value greater than 2.

trim_name	(Input; optional) Must be a scalar of type logical. If the value is FALSE, then trailing blanks in name are considered significant. Otherwise, they are not considered part of the environment variable's name.
errmsg	(Input; output; optional) Must be a scalar of type default character. If an error occurs, it is assigned a processor-dependent explanatory message; otherwise, it is unchanged.

Example

The following program asks for the name of an environment variable. If the environment variable exists in the program's environment, it prints out its value:

```
program print_env_var
character name*20, val*40
integer len, status
write (*,*) 'enter the name of the environment variable'
read (*,*) name
call get_environment_variable (name, val, len, status, .true.)
if (status .ge. 2) then
   write (*,*) 'get_environment_variable failed: status = ', status
   stop
end if
if (status .eq. 1) then
   write (*,*) 'env var does not exist'
   stop
end if
if (status .eq. -1) then
   write (*,*) 'env var length = ', len, ' truncated to 40'
   len = 40
end if
if (len .eq. 0) then
   write (*,*) 'env var exists  but has no value'
   stop
end if
write (*,*) 'env var value = ', val (1:len)
end
```

When the above program is invoked, the following line is displayed:

```
enter the name of the environment variable
```

The following shows an example of what could be displayed if you enter "HOME".

- On a Linux* system:

```
env var value = /home/our_space/usr4
```

- On a Windows* system:

```
env var value = C:/
```

The following shows an example of what could be displayed if you enter "PATH".

- On a Linux system:

```
env var length =          307  truncated to 40
env var value = /site/our_space/usr4/progs/build_area
```

- On a Windows system:

```
env var length =          829  truncated to 40
env var value = C:\OUR_SPACE\BUILD_AREA\build_objects\
```

GETENVQQ

Portability Function: *Returns the value of an environment variable.*

Module

USE IFPORT

Syntax

`result = GETENVQQ (varname,value)`

varname	(Input) Character*(*). Name of environment variable.
value	(Output) Character*(*). Value of the specified environment variable, in uppercase.

Results

The result type is INTEGER(4). The result is the length of the string returned in *value*. Zero is returned if the given variable is not defined.

GETENVQQ searches the list of environment variables for an entry corresponding to *varname*. Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQQ uses the C runtime routine getenv and SETENVQQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the runtime library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system's environment.

Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQQ.

GETENVQQ and SETENVQQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

Example

```
!  Program to demonstrate GETENVQQ and SETENVQQ
USE IFPORT
USE IFCORE
INTEGER(4) lenv, lval
CHARACTER(80) env, val, enval
WRITE (*,900) ' Enter environment variable name to create, &
               modify, or delete: '
lenv = GETSTRQQ(env)
IF (lenv .EQ. 0) STOP
WRITE (*,900) ' Value of variable (ENTER to delete): '
```

```
lval = GETSTRQQ(val)
IF (lval .EQ. 0) val = ' '
enval = env(1:lenv) // '=' // val(1:lval)
IF (SETENVQQ(enval)) THEN
  lval = GETENVQQ(env(1:lenv), val)
  IF (lval .EQ. 0) THEN
    WRITE (*,*) 'Can''t get environment variable'
  ELSE IF (lval .GT. LEN(val)) THEN
    WRITE (*,*) 'Buffer too small'
  ELSE
    WRITE (*,*) env(:lenv), ': ', val(:lval)
    WRITE (*,*) 'Length: ', lval
  END IF
ELSE
  WRITE (*,*) 'Can''t set environment variable'
END IF
900  FORMAT (A, \)
END
```

SETENVQQ
GETLASTERRORQQ

GETEXCEPTIONPTRSQQ

Runtime Function: *Returns a pointer to C runtime exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.* *This routine is only available for Windows.*

Module

USE IFCORE

Syntax

```
result = GETEXCEPTIONPTRSQQ( )
```

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the *eptr* argument to routine TRACEBACKQQ to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling GETEXCEPTIONPTRSQQ is only valid within a user-defined handler that was established with SIGNALQQ or a direct call to the C rtl signal( ) function.

For a full description of exceptions and error handling, see Error Handling.

Example

```
  PROGRAM SIGTEST
  USE IFCORE
  ...
  R3 = 0.0E0
  STS = SIGNALQQ(MY_HANDLER)
  ! Cause a divide by zero exception
  R1 = 3.0E0/R3
```

```
...
END
INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM)
USE IFCORE
...
EPTRS = GETEXCEPTIONPTRSQQ()
...
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)
...
MY_HANDLER = 1
END
```

GETFILEINFOQQ

Portability Function: *Returns information about the specified file. File names can contain wildcards (* and ?).*

Module

USE IFPORT

Syntax

`result = GETFILEINFOQQ (files,buffer,handle)`

files
(Input) Character*(*). Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).

buffer
(Output) Derived type `FILE$INFO` or derived type `FILE$INFOI8`. Information about a file that matches the search criteria in *files*.

The derived type `FILE$INFO` is defined in `IFPORT.F90` as follows:

```
TYPE FILE$INFO
  INTEGER(4) CREATION             ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE            ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS           ! LAST ACCESS (-1 on FAT)
  INTEGER(4) LENGTH               ! LENGTH OF FILE
  INTEGER(4) PERMIT               ! FILE ACCESS MODE
  CHARACTER(255) NAME             ! FILE NAME
END TYPE FILE$INFO
```

The derived type `FILE$INFOI8` is defined in `IFPORT.F90` as follows:

```
TYPE FILE$INFOI8
  INTEGER(4) CREATION             ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE            ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS           ! LAST ACCESS (-1 on FAT)
  INTEGER(8) LENGTH               ! LENGTH OF FILE
```

```
  INTEGER(4) PERMIT               ! FILE ACCESS MODE
  CHARACTER(255) NAME             ! FILE NAME
END TYPE FILE$INFOI8
```

handle (Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Control mechanism. One of the following constants, defined in `IFPORT.F90`:

- FILE$FIRST - First matching file found.
- FILE$LAST - Previous file was the last valid file.
- FILE$ERROR - No matching file found.

Results

The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.

The derived-type element variables FILE$INFO%CREATION, FILE$INFO%LASTWRITE, and FILE$INFO %LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively.

To break the time and date into component parts, call UNPACKTIMEQQ. FILE$INFO%LENGTH contains the length of the file in bytes. FILE$INFO%PERMIT contains a set of bit flags describing access information about the file as follows:

Bit flag	Access information for the file
FILE$ARCHIVE	Marked as having been copied to a backup device.
FILE$DIR	A subdirectory of the current directory. Each MS-DOS* directory contains two special files, "." and "..". These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory's parent directory.
FILE$HIDDEN	Hidden. It does not appear in the directory list you request from the command line, the Microsoft* visual development environment browser, or File Manager.
FILE$READONLY	Write-protected. You can read the file, but you cannot make changes to it.
FILE$SYSTEM	Used by the operating system.
FILE$VOLUME	A logical volume, or partition, on a physical disk drive. This type of file appears only in the root directory of a physical device.

You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILE$INFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILE $INFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERRORQQ to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

Example

```
USE IFPORT
USE IFCORE
  CALL SHOWPERMISSION( )
END

! SUBROUTINE to demonstrate GETFILEINFOQQ
SUBROUTINE SHOWPERMISSION( )
USE IFPORT
  CHARACTER(80) files
  INTEGER(KIND=INT_PTR_KIND( )) handle
  INTEGER(4) length
  CHARACTER(5) permit
  TYPE (FILE$INFO) info
    WRITE (*, 900) ' Enter wildcard of files to view: '
    900 FORMAT (A, \)

    length = GETSTRQQ(files)
    handle = FILE$FIRST

    DO WHILE (.TRUE.)
      length = GETFILEINFOQQ(files, info, handle)
      IF ((handle .EQ. FILE$LAST) .OR. &
          (handle .EQ. FILE$ERROR)) THEN
         SELECT CASE (GETLASTERRORQQ( ))
           CASE (ERR$NOMEM)
             WRITE (*,*) 'Out of memory'
           CASE (ERR$NOENT)
             EXIT
           CASE DEFAULT
             WRITE (*,*) 'Invalid file or path name'
         END SELECT
      END IF

      permit = ' '
      IF ((info%permit .AND. FILE$HIDDEN) .NE. 0) &
         permit(1:1) = 'H'
      IF ((info%permit .AND. FILE$SYSTEM) .NE. 0) &
         permit(2:2) = 'S'
      IF ((info%permit .AND. FILE$READONLY) .NE. 0) &
         permit(3:3) = 'R'
      IF ((info%permit .AND. FILE$ARCHIVE) .NE. 0) &
         permit(4:4) = 'A'
      IF ((info%permit .AND. FILE$DIR) .NE. 0) &
         permit(5:5) = 'D'
      WRITE (*, 9000) info%name, info%length, permit
      9000 FORMAT (1X, A5, I9, ' ',A6)
    END DO
END SUBROUTINE
```

UNPACKTIMEQQ

GETGID

Portability Function: *Returns the group ID of the user of a process.*

Module

USE IFPORT

Syntax

```
result = GETGID( )
```

Results

The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity the program is running. The result is returned as follows:

- **Linux**

  This function returns the group identity for the current process.
- **Windows**

  This function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.

  Note that on Windows systems, domain accounts and local accounts can overlap.

Example

```
USE IFPORT
ISTAT = GETGID( )
```

GETLASTERROR

Portability Function: *Returns the last error set.*

Module

USE IFPORT

Syntax

```
result = GETLASTERROR( )
```

Results

The result type is INTEGER(4). The result is the integer corresponding to the last runtime error value that was set.

For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining `errno`. Your application can then take appropriate action based upon the error number.

GETLASTERRORQQ

Portability Function: *Returns the last error set by a runtime procedure.*

Module

USE IFPORT

Syntax

```
result = GETLASTERRORQQ( )
```

Results

The result type is INTEGER(4). The result is the most recent error code generated by a runtime procedure.

Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERRORQQ retrieves the most recent error message. The error constants are defined in `IFPORT.F90`. The following table shows some library routines and the errors each routine produces:

Library routine	Errors produced
BEEPQQ	no error
BSEARCHQQ	ERR$INVAL
CHANGEDIRQQ	ERR$NOMEM, ERR$NOENT
CHANGEDRIVEQQ	ERR$INVAL, ERR$NOENT
COMMITQQ	ERR$BADF
DELDIRQQ	ERR$NOMEM, ERR$ACCES, ERR$NOENT
DELFILESQQ	ERR$NOMEM, ERR$ACCES, ERR$NOENT, ERR $INVAL
FINDFILEQQ	ERR$NOMEM, ERR$NOENT
FULLPATHQQ	ERR$NOMEM, ERR$INVAL

GETLOG

Portability Subroutine: *Returns the user's login name.*

Module

USE IFPORT

Syntax

```
CALL GETLOG (name)
```

name (Output) Character*(*). User's login name.

The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it is truncated. The actual parameter corresponding to *name* should be long enough to hold the login name. If the supplied actual parameter is too short to hold the login name, the login name is truncated.

If the login name is shorter than the actual parameter corresponding to *name*, the login name is padded with blanks at the end, until it reaches the length of the actual parameter.

If the login name cannot be determined, all blanks are returned.

Example

```
use IFPORT
character*20 username
CALL GETLOG (username)
print *, "You logged in as ",username
```

GETPID

Portability Function: *Returns the process ID of the current process.*

Module

USE IFPORT

Syntax

```
result = GETPID( )
```

Results

The result type is INTEGER(4). The result is the process ID number of the current process.

Example

```
USE IFPORT
INTEGER(4) istat
istat = GETPID()
```

GETPOS, GETPOSI8

Portability Functions: *Return the current position of a file.*

Module

USE IFPORT

Syntax

`result = GETPOS (lunit)`

`result = GETPOSI8 (lunit)`

lunit	(Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and the file must be connected.

Results

The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the offset, in bytes, from the beginning of the file. If an error occurs, the result value is -1 and the following error code is returned in `errno`:

EINVAL: *lunit* is not a valid unit number, or is not open.

These functions are equivalent to FTELL, FTELLI8.

GETSTATUSFPQQ

Portability Subroutine: *Returns the floating-point processor status word. This routine is only available for Windows.*

Module

USE IFPORT

Syntax

`CALL GETSTATUSFPQQ (status)`

status	(Output) INTEGER(2). Floating-point processor status word.

The floating-point status word shows whether various floating-point exception conditions have occurred. The compiler initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

Parameter name	Hex value	Description
FPSW$MSW_EM	Z'003F'	Status Mask (set all flags to 1)
FPSW$INVALID	Z'0001'	An invalid result occurred
FPSW$DENORMAL	Z'0002'	A subnormal (very small number) occurred
FPSW$SUBNORMAL	Z'0002'	A subnormal (very small number) occurred
FPSW$ZERODIVIDE	Z'0004'	A divide by zero occurred
FPSW$OVERFLOW	Z'0008'	An overflow occurred
FPSW$UNDERFLOW	Z'0010'	An underflow occurred
FPSW$INEXACT	Z'0020'	Inexact precision occurred

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause runtime errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

Example

```
!  Program to demonstrate GETSTATUSFPQQ
 USE IFPORT
 INTEGER(2) status
 CALL GETSTATUSFPQQ(status)
!  check for divide by zero
 IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
   WRITE (*,*) 'Divide by zero occurred. Look    &
   for NaN or signed infinity in resultant data.'
 END IF
END
```

GETSTRQQ

Runtime Function: *Reads a character string from the keyboard using buffered input.*

Module

USE IFCORE

Syntax

```
result = GETSTRQQ (buffer)
```

buffer	(Output) Character*(*). Character string returned from keyboard, padded on the right with blanks.

Results

The result type is INTEGER(4). The result is the number of characters placed in *buffer*.

The function does not complete until you press Return or Enter.

Example

```
!  Program to demonstrate GETSTRQQ
 USE IFCORE
 USE IFPORT
 INTEGER(4) length, result
 CHARACTER(80) prog, args
 WRITE (*, '(A, \)') ' Enter program to run: '
 length = GETSTRQQ (prog)
 WRITE (*, '(A, \)') ' Enter arguments: '
 length = GETSTRQQ (args)
 result = RUNQQ (prog, args)
 IF (result .EQ. -1) THEN
   WRITE (*,*) 'Couldn''t run program'
 ELSE
   WRITE (*, '(A, Z4, A)') 'Return code : ', result, 'h'
 END IF
 END
```

PEEKCHARQQ

GET_TEAM

Transformational Intrinsic Function (Generic):
Returns a copy of a team variable.

Syntax

```
result = GET_TEAM ([ level ])
```

level	(Optional, Input) Must be a scalar integer whose value is equal to one of the named constants INITIAL_TEAM, CURRENT_TEAM, or PARENT_TEAM defined in the ISO_FORTRAN_ENV intrinsic module.

Results

The result is type TEAM_TYPE from the ISO_FORTRAN_ENV intrinsic module. If *level* is not present, or if CURRENT_TEAM is specified, the result is a team variable describing the current team. If *level* has the value PARENT_TEAM, the result is a team variable describing the parent team of the current team. If *level* has the value INITIAL_TEAM, the result is a team variable describing the initial team.

Example

Consider the following program fragment:

```
PROGRAM main
USE, INTRINSIC       :: ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)     :: original
original = GET_TEAM (INITIAL_TEAM)
```

After execution of the GET_TEAM function, `original` is defined with a team value describing the initial team.

GETTIM

Portability Subroutine: *Returns the time.*

Module

USE IFPORT

Syntax

`CALL GETTIM (ihr, imin, isec, i100th)`

ihr	(Output) INTEGER(4) or INTEGER(2). Hour (0-23).
imin	(Output) INTEGER(4) or INTEGER(2). Minute (0-59).
isec	(Output) INTEGER(4) or INTEGER(2). Second (0-59).
i100th	(Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example

See the example in GETDAT.

SECNDS portability routine

TIME portability routine

TIMEF

GETTIMEOFDAY

Portability Subroutine: *Returns seconds and microseconds since 00:00 Jan 1, 1970.*

Module

USE IFPORT

Syntax

```
CALL GETTIMEOFDAY (ret, err)
```

ret (Output) INTEGER(4). One-dimensional array with 2 elements used to contain numeric time data. The elements of *ret* are returned as follows:

Element	Value
ret(1)	Seconds
ret(2)	Microseconds

err (Output) INTEGER(4).

If an error occurs, *err* contains a value equal to -1 and array *ret* contains zeros.

On Windows* systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

GETUID

Portability Function: *Returns the user ID of the calling process.*

Module

USE IFPORT

Syntax

```
result = GETUID( )
```

Results

The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:

- **Linux**

  This function returns the user identity for the current process.
- **Windows**

  This function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.

Note that on Windows systems, domain accounts and local accounts can overlap.

Example

```
USE IFPORT
integer(4) istat
istat = GETUID( )
```

GMTIME

Portability Subroutine: *Returns the Greenwich mean time in an array of time elements.*

Module

USE IFPORT

Syntax

CALL GMTIME (*stime*,*tarray*)

stime

(Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.

tarray

(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of *tarray* are returned as follows:

Element	Value
tarray(1)	Seconds (0-61, where 60-61 can be returned for leap seconds)
tarray(2)	Minutes (0-59)
tarray(3)	Hours (0-23)
tarray(4)	Day of month (1-31)
tarray(5)	Month (0-11)
tarray(6)	Number of years since 1900
tarray(7)	Day of week (0-6, where 0 is Sunday)
tarray(8)	Day of year (0-365)
tarray(9)	Daylight saving flag (0 if standard time, 1 if daylight saving time)

Caution
This subroutine may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```
use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
```

```
!   00:00:00 GMT January 1, 1970
stime = time()
CALL GMTIME (stime, timearray)
print *, timearray
end
```

DATE_AND_TIME

GOTO - Assigned

Statement: *Transfers control to the statement whose label was most recently assigned to a variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.*

Syntax

GOTO *var*[[,] (*label-list*)]

var	Is a scalar integer variable.
label-list	Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the assigned GO TO statement. The same label can appear more than once in this list.

The variable must have a statement label value assigned to it by an ASSIGN statement (not an arithmetic assignment statement) before the GO TO statement is executed.

If a list of labels appears, the statement label assigned to the variable is not checked against the labels in the list.

Both the assigned GO TO statement and its associated ASSIGN statement must be in the same scoping unit.

Example

The following example is equivalent to `GO TO 200`:

```
ASSIGN 200 TO IGO
GO TO IGO
```

The following example is equivalent to `GO TO 450`:

```
ASSIGN 450 TO IBEG
GO TO IBEG, (300,450,1000,25)
```

The following example shows an invalid use of an assigned variable:

```
ASSIGN 10 TO I
J = I
GO TO J
```

In this case, variable J is not the variable assigned to, so it cannot be used in the assigned GO TO statement.

The following shows another example:

```
    ASSIGN 10 TO N
    GOTO N
10  CONTINUE
```

The following example uses an assigned GOTO statement with a *label-list* but it is not checked against the value of VIEW:

```
ASSIGN 300 TO VIEW
    GOTO VIEW (100, 200, 400)   ! this will go to label 300
```

Obsolescent Language Features in the Fortran Standard
GOTO - Computed GOTO
GOTO - Unconditional GOTO
Execution Control

GOTO - Computed

Statement: *Transfers control to one of a set of labeled branch target statements based on the value of an expression. It is an obsolescent feature in Fortran 95.*

Syntax

`GOTO (label-list) [ ,] expr`

label-list	Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the computed GO TO statement. (Also called the *transfer list*.) The same label can appear more than once in this list.
expr	Is a scalar numeric expression in the range 1 to n, where *n* is the number of statement labels in *label-list*. If necessary, it is converted to integer data type.

When the computed GO TO statement is executed, the expression is evaluated first. The value of the expression represents the ordinal position of a label in the associated list of labels. Control is transferred to the statement identified by the label. For example, if the list contains (30,20,30,40) and the value of the expression is 2, control is transferred to the statement identified with label 20.

If the value of the expression is less than 1 or greater than the number of labels in the list, control is transferred to the next executable statement or construct following the computed GO TO statement.

Example

The following example shows valid computed GO TO statements:

```
GO TO (12,24,36), INDEX
GO TO (320,330,340,350,360), SITU(J,K) + 1
```

The following shows another example:

```
   next = 1
C
C  The following statement transfers control to statement 10:
C
   GOTO (10, 20) next
   ...
10 CONTINUE
   ...
20 CONTINUE
```

See Also

Obsolescent Language Features in the Fortran Standard

GOTO - Unconditional GOTO
Execution Control

GOTO - Unconditional

Statement: *Transfers control to the same branch target statement every time it executes.*

Syntax

```
GO TO label
```

label	Is the label of a valid branch target statement in the same scoping unit as the GO TO statement.

The unconditional GO TO statement transfers control to the branch target statement identified by the specified label.

Example

The following are examples of GO TO statements:

```
  GO TO 7734
  GO TO 99999
```

The following shows another example:

```
    integer(2) in
10  print *, 'enter a number from one to ten: '
    read *, in
    select case (in)
    case (1:10)
      exit
    case default
      print *, 'wrong entry, try again'
      goto 10
    end select
```

GOTO - Computed GOTO
Execution Control

GROUPPRIVATE

OpenMP* Fortran Compiler Directive: *Specifies that a variable is replicated once for a group of threads participating in a parallel region. This feature is only available for ifx.*

Syntax

```
!$OMP GROUPPRIVATE (list)[clause [[,] clause]... ]
```

list	Is a comma-separated list of variables or named common blocks. A common block name must be enclosed in slashes (/ /). If a list item has the BIND attribute, the corresponding C entities must also appear in a GROUPPRIVATE directive. List items must have the SAVE attribute, either implicitly or explicitly, or be declared in the specification part of a module. List items cannot appear in an EQUIVALENCE statement, and they cannot be any of the following:

- Coarrays
- Associate names
- Elements of a COMMON block
- Initialized variables

clause — Is a DEVICE_TYPE (device) clause.

The GROUPPRIVATE directive is a declarative directive that must appear in the specification part of the scope where its list items are declared. If a list item is a COMMON block name, all scopes that declare a COMMON block with the same name must contain a GROUPPRIVATE directive containing the COMMON block name enclosed in slashes.

GROUPPRIVATE directives containing COMMON block names must appear after the last COMMON statement declaring a COMMON block that appears as a list item in that directive.

List items in a GROUPPRIVATE directive are replicated such that there is one copy for each contention group. A contention group consists of all implicit tasks and their descendent tasks generated in an implicit parallel region R, and all nested regions for which R is the innermost enclosing parallel region.

List items are uninitialized when they are replicated, and their lifetime is limited to that of all tasks in the contention group. References to list items refer to the GROUPPRIVATE copy created for the contention group of the innermost enclosing implicit parallel region.

If no DEVICE_TYPE clause appears, the behavior is as if DEVICE_TYPE (ANY) had been specified.

References to GROUPPRIVATE list items in a DO CONCURRENT construct are undefined.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

H to I

This section describes language features that start with H or I.

H to I
HINT

Parallel Directive Clause: *Provides information about the expected runtime behavior of the region that corresponds to the construct where it is specified for optimization purposes.*

Syntax

```
HINT (hint-expression)
```

hint-expression — Is an integer expression with a kind type of OMP_SYNC_HINT_KIND with a value that is a valid synchronization hint.

The HINT clause provides information about the expected runtime properties of the construct where it appears. It does not change the semantics of the construct.

If a HINT clause does not appear in a construct that accepts a HINT clause, it is as if HINT (OMP_SYNC_HINT_NONE) appears in the construct.

The predefined KIND type OMP_SYNC_HINT_KIND is used to specify the kind-type parameter for an integer that is to be used in *hint-expression*. The following table lists the predefined synchronization HINT constants. They appear in the Fortran module file `omp_lib.mod` and the Fortran include file `omp_lib.h`.

Synchronization HINT constant name	Value	Description
OMP_SYNC_HINT_NONE	0	Provides documentation clarity. It has no effect on the construct transformation.
OMP_SYNC_HINT_UNCONTENDED	1	Indicates low contention in the construct. Few threads are expected to encounter the region at the same time in a manner requiring synchronization.
OMP_SYNC_HINT_CONTENDED	2	Indicates high contention in the construct. Many threads will encounter the region at the same time requiring synchronization.
OMP_SYNC_HINT_SPECULATIVE	4	Suggests that the operation be implemented using speculative techniques such as transactional memory.
OMP_SYNC_HINT_NONSPECULATIVE	8	Suggests that the operation *not* be implemented using speculative techniques such as transactional memory.

Synchronization HINT constants can be combined in expressions with the plus (+) operator. Combining a synchronization HINT constant with OMP_SYNC_HINT_NONE is the same as just specifying the synchronization HINT constant alone.

You cannot combine the following HINT constants:

- OMP_SYNC_HINT_UNCONTENDED and OMP_SYNC_HINT_CONTENDED
- OMP_SYNC_HINT_SPECULATIVE and OMP_SYNC_HINT_NONSPECULATIVE

An implementation can provide additional pre-defined synchronization HINT constants.

CRITICAL directive

HOSTNAM

Portability Function: *Returns the current host computer name. This function can also be specified as HOSTNM.*

Module

USE IFPORT

Syntax

```
result = HOSTNAM (name)
```

name	(Output) Character*(*). Name of the current host. Should be at least as long as MAX_HOSTNAM_LENGTH + 1. MAX_HOSTNAM_LENGTH is defined in the IFPORT module.

Results

The result type is INTEGER(4). The result is zero if successful. If *name* is not long enough to contain all of the host name, the function truncates the host name and returns -1.

Example

```
use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
```

HUGE

Inquiry Intrinsic Function (Generic): *Returns the largest number in the model representing the same type and kind parameters as the argument.*

Syntax

`result = HUGE (x)`

x	(Input) Must be of type integer or real; it can be scalar or array valued.

Results

The result is a scalar of the same type and kind parameters as *x*. If *x* is of type integer, the result has the value $r^q - 1$. If *x* is of type real, the result has the value $(1 - b^{-p})b^{e_{max}}$.

Integer parameters *r* and *q* are defined in Model for Integer Data; real parameters *b*, *p*, and e_{max} are defined in Model for Real Data.

Example

If X is of type REAL(4), HUGE (X) has the value $(1 - 2^{-24}) \times 2^{128}$.

See Also

TINY

Data Representation Models

HYPOT

Elemental Intrinsic Function (Generic): *Returns the value of the Euclidean distance of the arguments.*

Syntax

`result = HYPOT (x,y)`

x	(Input) Must be of type real.
y	(Input) Must be of type real. It must be the same type and kind as *x*.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the Euclidean distance, $\sqrt{X^2 + Y^2}$, without undue overflow or underflow.

Example

HYPOT (3.0, 4.0) has the approximate value 5.0.

IACHAR

Elemental Intrinsic Function (Generic): *Returns the position of a character in the ASCII character set, even if the processor's default character set is different. In Intel® Fortran, IACHAR is equivalent to the ICHAR function.*

Syntax

```
result = IACHAR (c [, kind])
```

c	(Input) Must be of type character of length 1.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If *c* is in the ASCII collating sequence, the result is the position of *c* in that sequence and satisfies the inequality (0 .le. IACHAR(c) .le. 127).

The results must be consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE(C, D) is true, IACHAR(C) .LE. IACHAR(D) is also true.

Example

IACHAR ('Y') has the value 89.

IACHAR ('%') has the value 37.

IALL

Transformational Intrinsic Function (Generic): *Reduces an array with a bitwise AND operation.*

Syntax

```
result = IALL (array, dim [, mask])
result = IALL (array [, mask])
```

array	(Input) Must be an array of type integer.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.

Results

The result has the same type and kind parameters as *array*. It is scalar if *dim* does not appear or if *array* has rank one; otherwise, the result is an array of rank *n* - 1 and shape [d_1, d_2, ..., d_{dim-1}, d_{dim+1} , ..., d_n] where [d_1, d_2,..., d_n] is the shape of *array*.

If *array* has size zero the result value is equal to NOT (INT (0, KIND (*array*))). Otherwise, the result of IALL (*array*) has a value equal to the bitwise AND of all the elements of *array*.

The result of IALL (*array*, MASK=*mask*) has a value equal to IALL (PACK (*array*, *mask*)).

The result of IALL (*array*, DIM=*dim* [, MASK=*mask*]) has a value equal to that of IALL (*array* [, MASK=*mask*]) if *array* has rank one. Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1} , ..., s_n) of the result is equal to IALL (*array* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n) [, MASK = *mask* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n)]).

Example

IALL ([14, 13, 11]) has the value 8. IALL ([14, 13, 11], MASK=[.true., .false., .true]) has the value 10.

See Also

IANY
IPARITY

IAND

Elemental Intrinsic Function (Generic): *Performs a logical AND on corresponding bits. This function can also be specified as AND.*

Syntax

```
result = IAND (i,j)
```

i — (Input) Must be of type integer or logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j — (Input) Must be of type integer or logical, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer or logical, they must have the same kind type parameter. If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. *i* and *j* must not both be binary, octal, or hexadecimal literal constants.

Results

If both *i* and *j* are of type integer or logical, the result type and kind are the same as *i*. If either *i* or *j* is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining *i* and *j* bit-by-bit according to the following truth table:

i	j	IAND (i, j)
1	1	1
1	0	0
0	1	0
0	0	0

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BIAND	INTEGER(1)	INTEGER(1)
IIAND [1]	INTEGER(2)	INTEGER(2)
JIAND	INTEGER(4)	INTEGER(4)
KIAND	INTEGER(8)	INTEGER(8)

[1]Or HIAND.

Example

IAND (2, 3) has the value 2.

IAND (4, 6) has the value 4.

The following shows another example:

```
INTEGER(1) i, m
INTEGER result
INTEGER(2) result2
i = 1
m = 3
result = IAND(i,m) ! returns an integer of default type
        ! (INTEGER(4) unless reset by user) whose
        ! value = 1
result2 = IAND(i,m) ! returns an INTEGER(2) with value = 1
```

IANY

Transformational Intrinsic Function (Generic):
Reduces an array with a bitwise OR operation.

Syntax

`result = IANY (array, dim [, mask])`

`result = IANY (array [, mask])`

array	(Input) Must be an array of type integer.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.

Results

The result has the same type and kind parameters as *array*. It is scalar if *dim* does not appear; otherwise, the result is an array of rank *n* - 1 and shape [d_1, d_2, ..., d_{dim-1}, d_{dim+1} , ..., d_n] where [d_1, d_2,..., d_n] is the shape of *array*.

The result of IANY (*array*) is the bitwise OR of all the elements of *array*. If *array* has size zero, the result value is equal to zero.

The result of IANY (*array*, MASK=*mask*) has a value equal to IANY (PACK (*array*, *mask*)).

The result of IANY (*array*, DIM=*dim* [, MASK=*mask*]) has a value equal to that of IANY (*array* [, MASK=*mask*]) if *array* has rank one. Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1} , ..., s_n) of the result is equal to IANY (*array* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n) [, MASK = *mask* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n)]).

Example

IANY ([14, 13, 8]) has the value 15. IANY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 14.

IALL
IPARITY

IARGC

Inquiry Intrinsic Function (Specific): *Returns the index of the last command-line argument. It cannot be passed as an actual argument. This function can also be specified as IARG or NUMARG.*

Syntax

```
result = IARGC( )
```

Results

The result type is INTEGER(4). The result is the index of the last command-line argument, which is also the number of arguments on the command line. The command is not included in the count. For example, IARGC returns 3 for the command-line invocation of `PROG1 -g -c -a`.

IARGC returns a value that is 1 less than that returned by NARGS.

Example

```
integer(4) no_of_arguments
no_of_arguments = IARGC ()
print *, 'total command line arguments are ', no_of_arguments
```

For a command-line invocation of `PROG1 -g -c -a`, the program above prints:

```
total command line arguments are 3
```

GET_COMMAND_ARGUMENT

IBCHNG

Elemental Intrinsic Function (Generic): *Reverses the value of a specified bit in an integer.*

Syntax

```
result = IBCHNG (i,pos)
```

i	(Input) Must be of type integer or of type logical (which is treated as an integer). This argument contains the bit to be reversed.
pos	(Input) Must be of type integer. This argument is the position of the bit to be changed. The rightmost (least significant) bit of *i* is in position 0.

Results

The result type and kind are the same as *i*. The result is equal to *i* with the bit in position *pos* reversed.

For more information, see Bit Functions.

Example

```
INTEGER J, K
J = IBCHNG(10, 2)     ! returns 14 = 1110
K = IBCHNG(10, 1)     ! returns 8 = 1000
```

IBCLR

Elemental Intrinsic Function (Generic): *Clears one bit to zero.*

Syntax

```
result = IBCLR (i,pos)
```

i	(Input) Must be of type integer or of type logical (which is treated as an integer).
pos	(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(*i*). The rightmost (least significant) bit of *i* is in position 0.

Results

The result type and kind are the same as *i*. The result has the value of the sequence of bits of *i*, except that bit *pos* of *i* is set to zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BBCLR	INTEGER(1)	INTEGER(1)
IIBCLR[1]	INTEGER(2)	INTEGER(2)
JIBCLR	INTEGER(4)	INTEGER(4)
KIBCLR	INTEGER(8)	INTEGER(8)

[1]Or HBCLR.

Example

IBCLR (18, 1) has the value 16.

If V has the value (1, 2, 3, 4), the value of IBCLR (POS = V, I = 15) is (13, 11, 7, 15).

The following shows another example:

```
INTEGER J, K
J = IBCLR(7, 1) ! returns 5 = 0101
K = IBCLR(5, 1) ! returns 5 = 0101
```

IBITS

Elemental Intrinsic Function (Generic): *Extracts a sequence of bits (a bit field).*

Syntax

`result = IBITS (i,pos,len)`

i	(Input) Must be of type integer.
pos	(Input) Must be of type integer. It must not be negative and *pos*+ *len* must be less than or equal to BIT_SIZE(*i*). The rightmost (least significant) bit of *i* is in position 0.

len	(Input) Must be of type integer. It must not be negative.

Results

The result type and kind are the same as *i*. The result has the value of the sequence of *len* bits in *i*, beginning at *pos*, right-adjusted and with all other bits zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BBITS	INTEGER(1)	INTEGER(1)
IIBITS[1]	INTEGER(2)	INTEGER(2)
JIBITS	INTEGER(4)	INTEGER(4)
KIBITS	INTEGER(8)	INTEGER(8)

[1] Or HBITS

Example

IBITS (12, 1, 4) has the value 6.

IBITS (10, 1, 7) has the value 5.

IBSET

Elemental Intrinsic Function (Generic): *Sets one bit to 1.*

Syntax

```
result = IBSET (i,pos)
```

i	(Input) Must be of type integer or of type logical (which is treated as an integer).
pos	(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(*i*).
	The rightmost (least significant) bit of *i* is in position 0.

Results

The result type and kind are the same as *i*. The result has the value of the sequence of bits of *i*, except that bit *pos* of *i* is set to 1.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BBSET	INTEGER(1)	INTEGER(1)
IIBSET[1]	INTEGER(2)	INTEGER(2)
JIBSET	INTEGER(4)	INTEGER(4)
KIBSET	INTEGER(8)	INTEGER(8)

[1]Or HBSET.

Example

IBSET (8, 1) has the value 10.

If V has the value (1, 2, 3, 4), the value of IBSET (POS = V, I = 2) is (2, 6, 10, 18).

The following shows another example:

```
INTEGER I
I = IBSET(8, 2) ! returns 12 = 1100
```

ICHAR

Elemental Intrinsic Function (Generic): *Returns the position of a character in the processor's character set.*

Syntax

```
result = ICHAR (c [, kind])
```

c	(Input) Must be of type character of length 1.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer.

The result value is the position of *c* in the processor's character set. *c* is in the range zero to n - 1, where *n* is the number of characters in the character set.

For any characters C and D (capable of representation in the processor), C .LE. D is true only if ICHAR(C) .LE. ICHAR(D) is true, and C .EQ. D is true only if ICHAR(C) .EQ. ICHAR(D) is true.

Specific Name	Argument Type	Result Type
	CHARACTER	INTEGER(2)
ICHAR [1]	CHARACTER	INTEGER(4)
	CHARACTER	INTEGER(8)

[1]This specific function cannot be passed as an actual argument.

Example

ICHAR ('W') has the value 87.

ICHAR ('#') has the value 35.

IDATE Intrinsic Procedure

Intrinsic Subroutine (Generic): *Returns three integer values representing the current month, day, and year. IDATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL IDATE (i, j, k)
```

i	(Output) Must be of type integer. It is the current month.
j	(Output) Must be of type integer with the same kind type parameter as *i*. It is the current day.
k	(Output) Must be of type integer with the same kind type parameter as *i*. It is the current year.

The current month is returned in *i*; the current day in *j*. The last two digits of the current year are returned in *k*.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

If the current date is September 16, 1999, the values of the integer variables upon return are: I = 9, J = 16, and K = 99.

See Also

DATE intrinsic procedure

DATE_AND_TIME

GETDAT

IDATE portability routine

IDATE Portability Routine

Portability Subroutine: *Returns the month, day, and year of the current system. IDATE can be used as a portability subroutine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.*

Module

USE IFPORT

Syntax

`CALL IDATE (i, j, k)`

-or-

`CALL IDATE (iarray)`

i	(Output) INTEGER(4). Is the current system month.
j	(Output) INTEGER(4). Is the current system day.
k	(Output) INTEGER(4). Is the current system year as an offset from 1900.
iarray	(Output) INTEGER(4). Is a three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is greater than or equal to 1969 and is returned as 2 digits.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

Consider the following:

```
    use IFPORT
    integer(4) imonth, iday, iyear, datarray(3)
! If the date is July 11, 1999:
    CALL IDATE(IMONTH, IDAY, IYEAR)
! sets IMONTH to 7, IDAY to 11 and IYEAR to 99.
    CALL IDATE (DATARRAY)
! datarray is (/11,7,99/)
```

See Also

DATE portability routine

DATE_AND_TIME

GETDAT

IDATE intrinsic procedure

IDATE4

Portability Subroutine: *Returns the month, day, and year of the current system.*

Module

USE IFPORT

Syntax

```
CALL IDATE4 (i,j,k)
```

-or-

```
CALL IDATE4 (iarray)
```

i	(Output) INTEGER(4). The current system month.
j	(Output) INTEGER(4). The current system day.
k	(Output) INTEGER(4). The current system year as an offset from 1900.
iarray	(Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

IDENT

General Compiler Directive: *Specifies a string that identifies an object module. The compiler places the string in the identification field of an object module when it generates the module for each source program unit.*

Syntax

```
!DIR$ IDENT string
```

string	Is a character constant containing printable characters. The number of characters is limited by the length of the source line.

Only the first IDENT directive is effective; the compiler ignores any additional IDENT directives in a program unit or module.

See Also

General Compiler Directives

Syntax Rules for Compiler Directives

IDFLOAT

Portability Function: *Converts an INTEGER(4) argument to double-precision real type.*

Module

USE IFPORT

Syntax

```
result = IDFLOAT (i)
```

i (Input) Must be of type INTEGER(4).

Results

The result type is double-precision real (REAL(8) or REAL*8).

See Also

DFLOAT

IEEE_CLASS

Elemental Module Intrinsic Function (Generic):
Returns the IEEE class.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_CLASS (x)
```

x (Input) Must be of type REAL.

Results

The result is of type TYPE(IEEE_CLASS_TYPE). The result value is one of the following:

IEEE_SIGNALING_NAN	IEEE_NEGATIVE_NORMAL
IEEE_QUIET_NAN	IEEE_POSITIVE_DENORMAL
IEEE_POSITIVE_INF	IEEE_NEGATIVE_DENORMAL
IEEE_NEGATIVE_INF	IEEE_POSITIVE_ZERO
IEEE_POSITIVE_NORMAL	IEEE_NEGATIVE_ZERO

IEEE_CLASS does not return IEEE_OTHER_VALUE in Intel® Fortran.

Example

IEEE_CLASS(1.0) has the value IEEE_POSITIVE_NORMAL.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_COPY_SIGN

Elemental Module Intrinsic Function (Generic):
Returns an argument with a copied sign. This is equivalent to the IEEE copySign function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_COPY_SIGN (x,y)
```

x (Input) Must be of type REAL.

y (Input) Must be of type REAL.

Results

The result type and kind are the same as *x*. The result has the value *x* with the sign of *y*. This is true even for IEEE special values, such as NaN or infinity.

The flags information is returned as a set of 1-bit flags.

Example

The value of IEEE_COPY_SIGN (X,3.0) is ABS (X), even when X is NaN.

IEEE_FLAGS

Portability Function: *Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of ISO/IEC 60559:2020 arithmetic in a Fortran program.*

Module

USE IFPORT

Syntax

```
result = IEEE_FLAGS (action,mode,in,out)
```

action (Input) Character*(*). One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.

mode (Input) Character*(*). One of the following literal values: 'direction', 'precision', or 'exception'.

in (Input) Character*(*). One of the following literal values: 'inexact', 'division', 'underflow','overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive','extended', 'double', 'single', or ' ', which represents an unused (null) value.

out (Output) Must be at least CHARACTER*9. One of the literal values listed for *in*.

The descriptions for the values allowed for *in* and *out* can be summarized as follows:

Value	Description
'nearest'	Rounding direction flags
'tozero'	

Value	Description
'negative'	
'positive'	
'single'	Rounding precision flags
'double'	
'extended'	
'inexact'	Math exception flags
'underflow'	
'overflow'	
'division'	
'invalid'	
'all'	All math exception flags above
'common'	The math exception flags: 'invalid', 'division', 'overflow', and 'underflow'

The values for *in* and *out* depend on the *action* and *mode* they are used with. The interaction of the parameters can be summarized as follows:

Value of *action*	Value of *mode*	Value of *in*	Value of *out*	Functionality and return value
GET	'direction'	Null (' ')	One of 'nearest', 'tozero', 'negative', or 'positive'	Tests rounding direction settings. Returns the current setting, or 'not available'.
	'exception'	Null (' ')	One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'	Tests math exception settings. Returns the current setting, or 0.

Value of *action*	Value of *mode*	Value of *in*	Value of *out*	Functionality and return value
	'precision'	Null (' ')	One of 'single ', 'double ', or 'extended'	Tests rounding precision settings. Returns the current setting, or 'not available'.
SET	'direction'	One of 'nearest', 'tozero', 'negative', or 'positive'	Null (' ')	Sets a rounding direction.
	'exception'	One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'	Null (' ')	Sets a floating-point math exception.
	'precision'	One of 'single ', 'double ', or 'extended'	Null (' ')	Sets a rounding precision.
CLEAR	'direction'	Null (' ')	Null (' ')	Clears the *mode*. Sets rounding to 'nearest'. Returns 0 if successful.
	'exception'	One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'	Null (' ')	Clears the *mode*. Returns 0 if successful.

Value of *action*	Value of *mode*	Value of *in*	Value of *out*	Functionality and return value
	'precision'	Null (' ')	Null (' ')	Clears the *mode*. Sets precision to 'double' (Windows) or 'extended' (Linux). Returns 0 if successful.
CLEARALL	Null (' ')	Null (' ')	Null (' ')	Clears all flags. Sets rounding to 'nearest', sets precision to 'double' (Windows) or 'extended' (Linux), and sets all exception flags to 0. Returns 0 if successful.

Results

IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.

The flags information is returned as a set of 1-bit flags.

Example

The following example gets the highest priority exception that has a flag raised. It passes the input argument *in* as a null string:

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)
```

The following example sets the rounding direction to the default ('nearest'):

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out, in
iflag = ieee_flags('clear','direction', '', '' )
```

The following example clears all exceptions:

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear','exception', 'all', '' )
```

The following example restores default direction and precision settings, and sets all exception flags to 0:

```
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '')
```

The following example detects an underflow exception:

```
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'
```

IEEE_FMA

Elemental Module Intrinsic Function (Generic):
Returns the result of a fused multiply-add operation. This is equivalent to the IEEE fusedMultiplyAdd operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_FMA (a,b,c)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.
c	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is REAL with the same kind type parameter as *a*. When the result is in range, the value of the result is the mathematical value of (*a* * *b*) + *c* rounded according to the rounding mode of the representation method of *a*. Only the final step in the calculation may cause IEEE_INEXACT, IEEE_OVERFLOW, or IEEE_UNDERFLOW to signal; intermediate calculations do not.

This is the fusedMultiplyAdd operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_FMA (TINY(0.0), TINY(0.0) 1.0) is equal to 1.0 when the rounding mode is set to NEAREST. The exception IEEE_INEXACT is signaled.

IEEE_GET_FLAG

Elemental Module Intrinsic Subroutine (Generic): *Returns whether an exception flag is signaling.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

`CALL IEEE_GET_FLAG (flag, flag_value)`

flag	(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.
flag_value	(Output) Must be of type logical. If the exception in *flag* is signaling, the result is true; otherwise, false.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL ON
...
CALL IEEE_GET_FLAG(IEEE_INVALID, ON)
```

If flag IEEE_INVALID is signaling, the value of ON is true; if it is quiet, the value of ON is false.

IEEE_GET_HALTING_MODE

Elemental Module Intrinsic Subroutine (Generic): *Stores the halting mode for an exception.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

`CALL IEEE_GET_HALTING_MODE (flag, halting)`

flag	(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

	IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.
halting	(Output) Must be of type logical. If the exception in *flag* causes halting, the result is true; otherwise, false.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)    ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT) ! Restores halting
```

IEEE_EXCEPTIONS Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_MODES

Intrinsic Module Subroutine (Generic): *Stores the current IEEE floating-point modes. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_GET_MODES (*modes*)

modes	(Output) Must be scalar and of type TYPE (IEEE_MODES_TYPE). It is assigned the value of the floating-point modes.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_MODE_TYPE) MODES
...
CALL IEEE_GET_MODES (MODES) ! Stores the floating-point modes
CALL IEEE_SET_UNDERFLOW_MODE (.TRUE.) ! Sets the underflow mode to gradual
...
CALL IEEE_SET_MODES (MODES) ! Restores the floating-point modes
```

See Also

IEEE_EXCEPTIONS Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_ROUNDING_MODE

Intrinsic Module Subroutine (Generic): *Stores the current IEEE rounding mode. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

CALL IEEE_GET_ROUNDING_MODE (*round_value* [, *radix*])

round_value	(Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It returns one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, or IEEE_UP; otherwise, IEEE_OTHER. The result can only be used if IEEE_SET_ROUNDING_MODE is invoked.
radix	(Input; optional) Must be an integer scalar with a value of two or ten. The rounding mode queried is the binary rounding mode, unless *radix* is present with the value ten, in which case it is the decimal rounding mode queried.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE(IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE(ROUND)   ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE(IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE(ROUND)   ! Restores the previous rounding mode
```

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_STATUS

Intrinsic Module Subroutine (Generic): *Stores the current state of the floating-point environment. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_GET_STATUS (*status_value*)

status_value	(Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). It stores the floating-point status. The result can only be used if IEEE_SET_STATUS is invoked.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS    ! Can also use IEEE_ARITHMETIC
TYPE(IEEE_ STATUS_TYPE) STATUS
...
```

```
CALL IEEE_GET_STATUS(STATUS)   ! Stores the floating-point status
CALL IEEE_SET_FLAG(IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS(STATUS)   ! Restores the floating-point status
```

See Also

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_UNDERFLOW_MODE

Intrinsic Module Subroutine (Generic): *Stores the current underflow mode. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`CALL IEEE_GET_UNDERFLOW_MODE (gradual)`

gradual	(Output) Must be logical scalar. The result is true if the current underflow mode is gradual (IEEE subnormals are allowed) and false if the current underflow mode is abrupt (underflowed results are set to zero).

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL GRAD
...
CALL IEEE_GET_UNDERFLOW_MODE(GRAD)
IF (GRAD) THEN ! underflows are gradual
...
ELSE ! underflows are abrupt
...
END IF
```

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_HANDLER

Portability Function: *Establishes a handler for IEEE exceptions.*

Module

USE IFPORT

Syntax

`result = IEEE_HANDLER (action, exception, handler)`

action	(Input) Character*(*). One of the following literal IEEE actions: 'GET', 'SET', or 'CLEAR'. For more details on these actions, see IEEE_FLAGS.

exception	(Input) Character*(*). One of the following literal IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all' (which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division'). The flags 'all' or 'common' should only be used for actions SET or CLEAR.
handler	(Input) The address of an external signal-handling routine.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appear in the following table (defined in the IFPORT module):

FPE$INVALID	Invalid operation
FPE$ZERODIVIDE	Divide-by-zero
FPE$OVERFLOW	Numeric overflow
FPE$UNDERFLOW	Numeric underflow
FPE$INEXACT	Inexact result (precision)

'GET' actions return the location of the current handler routine for exception cast to an INTEGER.

Example

The following example creates a handler routine and sets it to trap divide-by-zero:

```
PROGRAM TEST_IEEE
 REAL :: X, Y, Z
 CALL FPE_SETUP
 X = 0.
 Y = 1.
 Z = Y / X
END PROGRAM
SUBROUTINE FPE_SETUP
USE IFPORT
IMPLICIT NONE
 INTERFACE
   SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
     INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
   END SUBROUTINE
 END INTERFACE
 INTEGER IR
 IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE FPE_SETUP
SUBROUTINE FPE_HANDLER(SIG, CODE)
 USE IFPORT
 IMPLICIT NONE
 INTEGER SIG, CODE
```

```
 IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *,'Occurred divide by zero.'
 CALL ABORT
END SUBROUTINE FPE_HANDLER
```

See Also

IEEE_FLAGS

IEEE_INT

Elemental Module Intrinsic Function (Generic):
Enables conversion to INTEGER type.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_INT (a, round [, kind])`

a	(Input) Must be of type REAL or INTEGER.
round	(Input) Must be of type IEEE_ROUND_TYPE.
kind	(Input; optional) Must be a scalar INTEGER constant.

Results

The result type is INTEGER. If *kind* is present, the kind type parameter is that specified by *kind*; otherwise, the kind type parameter is default integer.

The result is the value of *a* converted to integer according to the rounding mode specified by *round* if the values can be represented in the representation method of the result type kind; otherwise, the result is processor dependent and IEEE_INVALID is signaled.

The result must be consistent with the ISO/IEC 60559:2020 operation convertToInteger{round} or convertToIntegerExact{round}. The processor consistently chooses which operation is performed.

Example

The result value of IEEE_INT (63.5, IEEE_DOWN) is 63. If converToIntegerExact{round} is used, IEEE_INEXACT will signal.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_IS_FINITE

Elemental Module Intrinsic Function (Generic):
Returns whether an IEEE value is finite.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_IS_FINITE (x)`

x	(Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of *x* is finite; otherwise, false.

An IEEE value is finite if IEEE_CLASS(x) has one of the following values:

IEEE_POSITIVE_NORMAL	IEEE_NEGATIVE_DENORMAL
IEEE_NEGATIVE_NORMAL	IEEE_POSITIVE_ZERO
IEEE_POSITIVE_DENORMAL	IEEE_NEGATIVE_ZERO

Example

IEEE_IS_FINITE (-2.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_IS_NAN

Elemental Module Intrinsic Function (Generic):
Returns whether an IEEE value is Not-a-Number (NaN).

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_IS_NAN (x)
```

x (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of *x* is NaN; otherwise, false.

Example

IEEE_IS_NAN (SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_IS_NEGATIVE

Elemental Module Intrinsic Function (Generic):
Returns whether an IEEE value is negative.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_IS_NEGATIVE (x)
```

x (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of x is negative; otherwise, false.

An IEEE value is negative if IEEE_CLASS(x) has one of the following values::

IEEE_NEGATIVE_NORMAL	IEEE_NEGATIVE_ZERO
IEEE_NEGATIVE_DENORMAL	IEEE_NEGATIVE_INF

Example

IEEE_IS_NEGATIVE (2.0) has the value false.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_IS_NORMAL

Elemental Module Intrinsic Function (Generic):
Returns whether an IEEE value is normal.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_IS_NORMAL (x)
```

x (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of *x* is normal; otherwise, false.

An IEEE value is normal if IEEE_CLASS(x) has one of the following values:

IEEE_POSITIVE_NORMAL	IEEE_POSITIVE_ZERO
IEEE_NEGATIVE_NORMAL	IEEE_NEGATIVE_ZERO

Example

IEEE_IS_NORMAL (SQRT(-2.0)) has the value false if IEEE_SUPPORT_SQRT (-2.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_LOGB

Elemental Module Intrinsic Function (Generic):
Returns a floating-point value equal to the unbiased exponent of the argument. This is equivalent to the IEEE logB function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_LOGB (x)
```

x (Input) Must be of type REAL.

Results

The result type and kind are the same as *x*. The result has the value of the unbiased exponent of *x* if the value of *x* is not zero, infinity, or NaN. The value of the result is equal to EXPONENT(x) - 1.

If *x* is equal to 0, the result is -infinity if IEEE_SUPPORT_INF(x) is true; otherwise, -HUGE(x). In either case, the IEEE_DIVIDE_BY_ZERO exception is signaled.

Example

IEEE_LOGB (3.4) has the value 1.0; IEEE_LOGB (4.0) has the value 2.0.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_MAX_NUM

Inquiry Module Intrinsic Function (Generic):
Returns the maximum of two values. This is equivalent to the IEEE maxNum operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_MAX_NUM (x,y)
```

x (Input) Must be of type REAL.

y (Input) Must be of type REAL with the same kind type parameter as *x*.

Results

The result type is REAL with the same kind type parameter as *x*. The result is *x* if *y* < *x*. The result is *y* if *x* < *y*.

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either *x* or *y* (processor dependent). No exceptions are signaled unless *x* or *y* is a signaling NaN.

This is the maxNum operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_MAX_NUM (3.7, IEEE_VALUE (0.0, IEEE_SIGNALING_NAN)) is a NaN. The exception IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_MAX_NUM_MAG

Inquiry Module Intrinsic Function (Generic):
Returns the maximum magnitude of two values. This is equivalent to the IEEE maxNumMag operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_MAX_NUM_MAG (x,y)
```

x	(Input) Must be of type REAL.
y	(Input) Must be of type REAL with the same kind type parameter as *x*.

Results

The result type is REAL with the same kind type parameter as *x*. The result is *x* if ABS(*y*) < ABS(*x*). The result is the value of *y* if ABS(*x*) < ABS(*y*).

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet Nan. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either *x* or *y* (processor dependent). No exceptions are signaled unless *x* or *y* is a signaling NaN.

This is the maxNumMag operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_MAX_NUM_MAG (3.7, -7.5) is -7.5.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_MIN_NUM

Inquiry Module Intrinsic Function (Generic):
Returns the minimum of two values. This is equivalent to the IEEE minNum operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_MIN_NUM (x,y)
```

x	(Input) Must be of type REAL.
y	(Input) Must be of type REAL with the same kind type parameter as *x*.

Results

The result type is REAL with the same kind type parameter as *x*. The result is *x* if *x* < *y*. The result is *y* if *y* < *x*.

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either *x* or *y* (processor dependent). No exceptions are signaled unless *x* or *y* is a signaling NaN.

This is the minNum operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_MIN_NUM (3.7, IEEE_VALUE (0.0, IEEE_QUIET _NAN)) is 3.7. No exceptions are signaled.

See Also

IEEE_MIN_NUM_MAG

Inquiry Module Intrinsic Function (Generic):
Returns the minimum magnitude of two values. This is equivalent to the IEEE minNumMag operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_MIN_NUM_MAG (x,y)`

x	(Input) Must be of type REAL.
y	(Input) Must be of type REAL with the same kind type parameter as *x*.

Results

The result type is REAL with the same kind type parameter as *x*. The result is y if ABS(*y*) < ABS(*x*). The result is the value of *x* if ABS(*x*) < ABS(*y*).

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either *x* or *y* (processor dependent). No exceptions are signaled unless *x* or *y* is a signaling NaN.

This is the minNumMag operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_MIN_NUM_MAG (3.7, -7.5) is 3.7.

IEEE_NEXT_AFTER

Elemental Module Intrinsic Function (Generic):
Returns the next representable value after X toward Y. This is equivalent to the IEEE nextAfter function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_NEXT_AFTER (x,y)`

x (Input) Must be of type REAL.

y (Input) Must be of type REAL.

Results

The result type and kind are the same as x. If x is equal to y, the result is x; no exception is signaled. If x is not equal to y, the result has the value of the next representable neighbor of x toward y. The neighbors of zero (of either sign) are both nonzero.

The following exceptions are signaled under certain cases:

Exception	Signaled
IEEE_OVERFLOW	When X is finite but IEEE_NEXT_AFTER(X,Y) is infinite
IEEE_UNDERFLOW	When IEEE_NEXT_AFTER(X,Y) is subnormal
IEEE_INEXACT	In both the above cases

Example

The value of IEEE_NEXT_AFTER (2.0,3.0) is 2.0 + EPSILON (X).

See Also

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

IEEE_NEXT_DOWN

Elemental Module Intrinsic Function (Generic):
Returns the next lower adjacent machine number.
This is equivalent to the IEEE nextDown operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_NEXT_DOWN (x)
```

x (Input) Must be of type REAL.

Results

The result type and kind are the same as *x*. The value of the result is the greatest value that compares less than *x* - except when *x* has the value NaN, the result is NaN, and when *x* has the value - ∞ , the result is - ∞ . If *x* is a signaling NaN, IEEE_INVALID signals; otherwise, no exception is signaled.

This is the nextDown operation as specified in the ISO/IEC 60559:2020 standard.

Example

The value of IEEE_NEXT_DOWN(+0.0) is the negative subnormal number with the least magnitude if the value if IEEE_SUPPORT_SUBNORMAL (0.0) is .TRUE..

See Also

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

IEEE_NEXT_UP

Elemental Module Intrinsic Function (Generic):
Returns the next higher adjacent machine number. This is equivalent to the IEEE nextUp operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_NEXT_UP (x)
```

x	(Input) Must be of type REAL.

Results

The result type and kind are the same as *x*. The value of the result is the least value that compares greater than *x* - except when *x* has the value NaN, the result is NaN, and when *x* has the value + ∞, the result is + ∞. If *x* is a signaling NaN, IEEE_INVALID signals; otherwise, no exception is signaled.

This is the nextUp operation as specified in the ISO/IEC 60559:2020 standard.

Example

The value of IEEE_NEXT_UP (HUGE (x)) is + ∞ if the value of IEEE_SUPPORT_INF (x) is .true..

IEEE_QUIET_EQ

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for equality. This is equivalent to the IEEE compareQuietEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_QUIET_EQ (a,b)
```

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares equal to *b*. If *a* or *b* is a NaN, the result is false. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_EQ (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_QUIET_GE

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for greater than or equal. This is equivalent to the IEEE compareQuietGreaterEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_QUIET_GE (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares greater than or equal to *b*. If *a* or *b* is a NaN, the result is false. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietGreaterEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_GE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_QUIET_GT

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for greater than. This is equivalent to the IEEE compareQuietGreater operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_QUIET_GT (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares greater than *b*. If *a* or *b* is a NaN, the result is false. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietGreater operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_GT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_QUIET_LE

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for less than or equal. This is equivalent to the IEEE compareQuietLessEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_QUIET_LE (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares less than or equal to *b*. If *a* or *b* is a NaN, the result is false. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietLessEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_LE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_QUIET_LT

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for less than. This is equivalent to the IEEE compareQuietLess operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_QUIET_LT (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares less than *b*. If *a* or *b* is a NaN, the result is false. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietLess operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_LT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_QUIET_NE

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for inequality. This is equivalent to the IEEE compareQuietNotEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_QUIET_NE (a,b)
```

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares not equal to *b*. If *a* or *b* is a NaN, the result is true. IEEE_INVALID signals if either *a* or *b* is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietNotEqual operation specified as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_QUIET_NE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is true and no exception is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REAL

Elemental Module Intrinsic Function (Generic):
Enables conversion to REAL type.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_REAL (a [, kind])
```

a	(Input) Must be of type REAL or INTEGER.
kind	(Input; optional) Must be a scalar INTEGER constant.

Results

The result type is REAL. If *kind* is present, the kind type parameter is that specified by *kind*; otherwise, the kind type parameter is default real.

The result has the same value as *a* if that value is representable in the representation method of the result type kind; otherwise, it is rounded according to the current rounding mode.

The result must be consistent with the ISO/IEC 60559:2020 operation convertFromInt if *a* is an integer, and with operation convertFormat if *a* is real.

Example

The result value of IEEE_REAL (987) is 987.0.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REM

Elemental Module Intrinsic Function (Generic):
Returns the result of an exact remainder operation.
This is equivalent to the IEEE remainder function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_REM (x,y)`

x	(Input) Must be of type REAL.
y	(Input) Must be of type REAL with a radix that is the same as that of *x*.

Results

The result type is real with the kind type parameter of whichever argument has greater precision.

Regardless of the rounding mode, the result value is x - y*N, where N is the integer nearest to the value x / y. If |N – x / y | = 1/2, N is even. If the result value is zero, the sign is the same as x.

Example

The value of IEEE_REM (5.0,4.0) is 1.0; the value of IEEE_REM (2.0,1.0) is 0.0; the value of IEEE_REM (3.0,2.0) is -1.0.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_RINT

Elemental Module Intrinsic Function (Generic):
Returns an integer value rounded according to the current rounding mode.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_RINT (x [, round])`

x	(Input) Must be of type REAL.
round	(Input; optional) Must be of type TYPE (IEEE_ROUND_TYPE).

Results

The result type and kind are the same as *x*.

The value of the result is *x* rounded to an integer according to the current rounding mode if *round* is not present. If *round* is present, the value of the result is *x* rounded to an integer according to the mode specified by *round*; this is the operation roundToInteger (rounding) as specified by ISO/IEC 60559:2020.

If the result value is zero, the sign is the same as *x*.

The rounding mode specified by *round*, if present, is used to perform the conversion. The rounding mode before and after the call remains unchanged.

Example

If the current rounding mode is IEEE_UP, the value of IEEE_RINT (2.2) is 3.0.

If the current rounding mode is IEEE_NEAREST, the value of IEEE_RINT (2.2) is 2.0.

The value of IEEE_RINT (7.4, IEEE_DOWN) is 7.0.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SCALB

Elemental Module Intrinsic Function (Generic):
Returns the exponent of a radix-independent floating-point number. This is equivalent to the IEEE scalB function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_SCALB (x,i)`

x	(Input) Must be of type REAL.
i	(Input) Must be of type INTEGER.

Results

The result type and kind are the same as *x*. The result is *x* multiplied by 2**i, if the value can be represented as a normal number.

If x (2**i) is too small and there is a loss of accuracy, the exception IEEE_UNDERFLOW is signaled. The result value is the nearest number that can be represented with the same sign as *x*.

If *x* is finite and x (2**i) is too large, an IEEE_OVERFLOW exception occurs. If IEEE_SUPPORT_INF (x) is true, the result value is infinity with the same sign as *x*; otherwise, the result value is SIGN (HUGE(x), x).

If *x* is infinite, the result is the same as *x*; no exception is signaled.

Example

The value of IEEE_SCALB (2.0,3) is 16.0.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SELECTED_REAL_KIND

Transformational Module Intrinsic Function (Generic): *Returns the value of the kind parameter of an IEEE REAL data type.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_SELECTED_REAL_KIND ([p][,r][,radix])`

`p`	(Input; optional) Must be scalar and of type INTEGER.
`r`	(Input; optional) Must be scalar and of type INTEGER.
`radix`	(Input; optional) Must be scalar and of type INTEGER.

At least argument `p` or `r` must be present.

Results

If `p` or `r` is absent, the result is as if the argument was present with the value zero. If `radix` is absent, there is no requirement on the radix of the selected kind.

The result is a scalar of type default integer. The result has a value equal to a value of the kind parameter of an IEEE real data type with decimal precision, as returned by the function PRECISION, of at least *p* digits, a decimal exponent range, as returned by the function RANGE, of at least *r*, and a *radix*, as returned by the function RADIX, of *radix*.

If no such kind type parameter is available on the processor, the result is as follows:

- -1 if the precision is not available
- -2 if the exponent range is not available
- -3 if neither the precision nor the exponent range is available
- -4 if one but not both of the precision and the exponent range is available
- -5 if the radix is not available

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision.

Example

IEEE_SELECTED_REAL_KIND (6, 70, 2) = 8.

Model for Real Data
for information on the real model.

IEEE_SET_FLAG

Elemental Module Intrinsic Function (Generic):
Assigns a value to an exception flag. This is a pure subroutine.

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

`CALL IEEE_SET_FLAG (flag,flag_value)`

flag	(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.
flag_value	(Output) Must be of type logical. If it has the value true, the exception in *flag* is set to signal; otherwise, the exception is set to be quiet.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS   ! Can also use module IEEE_ARITHMETIC
...
CALL IEEE_SET_FLAG (IEEE_INVALID, .TRUE.) ! Sets the IEEE_INVALID flag to signal
```

See Also

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_HALTING_MODE

Elemental Module Intrinsic Function (Generic):
Controls halting or continuation after an exception. This is a pure subroutine.

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

`CALL IEEE_SET_HALTING_MODE (flag, halting)`

flag	(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW

halting (Input) Must be scalar and of type logical. If the value is true, the exception specified in *flag* will cause halting; otherwise, execution will continue after this exception.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting
```

See Also

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_MODES

Intrinsic Module Subroutine (Generic): *Restores the current IEEE floating-point modes. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

`CALL IEEE_SET_MODES (modes)`

modes (Input) Must be scalar and of type TYPE (IEEE_MODES_TYPE). Its value must be a value that was assigned to the modes argument of a previous call to IEEE_GET_MODES.

A call to IEEE_SET_MODES restores the value of the floating-point modes to the state at the time IEEE_GET_MODES was called.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_MODE_TYPE) MODES
...
CALL IEEE_GET_MODES (MODES) ! Stores the floating-point modes
CALL IEEE_SET_UNDERFLOW_MODE (.TRUE.) ! Sets the underflow mode to gradual
...
CALL IEEE_SET_MODES (MODES) ! Restores the floating-point modes
```

See Also

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_ROUNDING_MODE

Intrinsic Module Subroutine (Generic): *Sets the IEEE rounding mode. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

CALL IEEE_SET_ROUNDING_MODE (*round_value* [, *radix*])

round_value	(Input) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It specifies one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, IEEE_UP, or IEEE_OTHER.
radix	(Input; optional) Must be an integer scalar with a value of ten or two. The rounding mode set is the binary rounding mode unless *radix* is present with the value of ten, in which case it is the decimal rounding mode set.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE (IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE (ROUND)   ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE (IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE (ROUND)   ! Restores the previous rounding mode
```

IEEE_SET_STATUS

Intrinsic Module Subroutine (Generic): *Restores the state of the floating-point environment. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_SET_STATUS (*status_value*)

status_value	(Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). Its value must be set in a previous invocation of IEEE_GET_STATUS.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS (STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG (IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS (STATUS) ! Restores the floating-point status
```

IEEE_SET_UNDERFLOW_MODE

Intrinsic Module Subroutine (Generic): *Sets the current underflow mode. This is an impure subroutine.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`CALL IEEE_SET_UNDERFLOW_MODE (gradual)`

gradual	(Input) Must be scalar and of type logical. If it is true, the current underflow mode is set to gradual underflow (subnormals may be produced on underflow). If it is false, the current underflow mode is set to abrupt (underflowed results are set to zero).

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL :: SG
...
CALL IEEE_GET_UNDERFLOW_MODE (SG) ! Stores underflow mode
CALL IEEE_SET_UNDERFLOW_MODE (.FALSE.) ! Resets underflow mode
...                                    ! Abrupt underflows happens here
CALL IEEE_SET_UNDERFLOW_MODE (SG) ! Restores previous underflow mode
```

IEEE_SIGNALING_EQ

Elemental Module Intrinsic Function (Generic): *Performs a signaling comparison for equality. This is equivalent to the IEEE compareSignalingEqual operation.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_SIGNALING_EQ (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares equal to *b*. If *a* or *b* is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_EQ (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_GE

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for greater than or equal. This is equivalent to the IEEE compareSignalingGreaterEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SIGNALING_GE (a,b)
```

a (Input) Must be of type REAL.

b (Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares greater than or equal to *b*. If *a* or *b* is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingGreaterEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_GE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_GT

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for greater than. This is equivalent to the IEEE compareSignalingGreater operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SIGNALING_GT (a,b)
```

a (Input) Must be of type REAL.

b (Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares greater than *b*. If *a* or *b* is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingGreater operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_GT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_LE

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for less than or equal. This is equivalent to the IEEE compareSignalingLessEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_SIGNALING_LE (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares less than or equal to *b*. If *a* or *b* is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingLessEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_LE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_LT

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for less than. This is equivalent to the IEEE compareSignalingLess operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_SIGNALING_LT (a,b)`

a	(Input) Must be of type REAL.
b	(Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares less than *b*. If *a* or *b* is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingLess operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_LT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_NE

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for inequality. This is equivalent to the IEEE compareSignalingNotEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SIGNALING_NE (a,b)
```

a (Input) Must be of type REAL.

b (Input) Must be of type REAL with the same kind type parameter as *a*.

Results

The result type is default LOGICAL. It has the value true if *a* compares not equal to *b*. If *a* or *b* is a NaN, the result is true and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingNotEqual operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result value of IEEE_SIGNALING_NE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is true and IEEE_INVALID is signaled.

IEEE_SIGNBIT

Elemental Module Intrinsic Function (Generic):
Tests to determine if the argument's sign bit is set. This is equivalent to the IEEE isSignMinus operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SIGNBIT (x)
```

x (Input) Must be of type REAL.

Results

The result is a scalar of type default logical. The result has the value .true. if the sign bit of *x* is set (nonzero); otherwise, it has the value .false.. No exception is signaled even if *x* has the value of a signaling NaN.

This is the isSignMinus operation as specified in the ISO/IEC 60559:2020 standard.

Example

The result of IEEE_SIGNBIT (-3.14) is .true..

IEEE_SUPPORT_DATATYPE

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE arithmetic.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_DATATYPE ([x])
```

x	(Input; optional) Must be scalar and of type REAL.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports IEEE arithmetic for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports IEEE arithmetic for real variables of the same kind type parameter as *x*; otherwise, false.

If real values are implemented according to the IEEE standard except that underflowed values flush to zero (abrupt) instead of being subnormal.

Example

IEEE_SUPPORT_DATATYPE (3.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_DENORMAL

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE subnormal numbers.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_DENORMAL ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for real variables of the same kind type parameter as *x*; otherwise, false.

IEEE_SUPPORT_DENORMAL() and IEEE_SUPPORT_DENORMAL(0.0_16) return .TRUE. even though Intel® Fortran's implementation does not signal when an underflow results in a REAL(16) denormal value. Intel® Fortran's implementation does signal when an underflow results in a REAL(16) zero.

Example

IEEE_SUPPORT_DENORMAL () has the value true if IEEE subnormal numbers are supported for all real types.

IEEE_SUPPORT_DIVIDE

Inquiry Module Intrinsic Function (Generic): *Returns whether the processor supports IEEE divide.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_DIVIDE ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_DIVIDE ( ) has the value true if IEEE divide is supported for all real types.

IEEE_SUPPORT_FLAG

Transformational Module Intrinsic Function (Generic): *Returns whether the processor supports IEEE exceptions.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

```
result = IEEE_SUPPORT_FLAG (flag [, x])
```

flag	(Input) Must be a scalar of type TYPE (IEEE_FLAG_TYPE). Its value is one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.
x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports detection of the exception specified by *flag* for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports detection of the exception specified by *flag* for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_FLAG (IEEE_UNDERFLOW) has the value true if the IEEE_UNDERFLOW exception is supported for all real types.

IEEE_SUPPORT_HALTING

Transformational Module Intrinsic Function (Generic): *Returns whether the processor supports IEEE halting.*

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

```
result = IEEE_SUPPORT_HALTING(flag)
```

flag	(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

Results

The result is a scalar of type default logical. The result has the value true if the processor supports the ability to control halting after the exception specified by *flag*; otherwise, false.

Example

IEEE_SUPPORT_HALTING (IEEE_UNDERFLOW) has the value true if halting is supported after an IEEE_UNDERFLOW exception

IEEE_SUPPORT_INF

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE infinities.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_INF ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports IEEE infinities (positive and negative) for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports IEEE infinities for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_INF( ) has the value true if IEEE infinities are supported for all real types.

IEEE_SUPPORT_IO

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE base conversion rounding during formatted I/O.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_IO ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports base conversion rounding during formatted input and output for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports base conversion rounding during formatted input and output for real variables of the same kind type parameter as *x*; otherwise, false.

The base conversion rounding applies to modes IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.

Example

IEEE_SUPPORT_IO ( ) has the value true if base conversion rounding is supported for all real types during formatted I/O.

IEEE_SUPPORT_NAN

Inquiry Module Intrinsic Function (Generic): *Returns whether the processor supports IEEE Not-a-Number feature.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_NAN ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports NaNs for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports NaNs for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_NAN () has the value true if IEEE NaNs are supported for all real types.

IEEE_SUPPORT_ROUNDING

Transformational Module Intrinsic Function (Generic): *Returns whether the processor supports IEEE rounding mode.*

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_ROUNDING (round_value [, x])
```

round_value	(Input) Must be of type TYPE(IEEE_ROUND_TYPE). It specifies one of the following rounding modes: IEEE_AWAY, IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, and IEEE_UP.

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports the rounding mode specified by round_value for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports the rounding mode specified by round_value for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_ROUNDING (IEEE_DOWN) has the value true if rounding mode IEEE_DOWN is supported for all real types.

IEEE_SUPPORT_SQRT

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE SQRT (square root).

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_SQRT ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor implements SQRT in accord with the IEEE standard for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor implements SQRT in accord with the IEEE standard for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_SQRT ( ) has the value true if IEEE SQRT is supported for all real types.

IEEE_SUPPORT_STANDARD

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE features defined in the standard.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_STANDARD ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. The result has the value true if the results of all the following functions are true (x can be omitted):

IEEE_SUPPORT_DATATYPE([x])
IEEE_SUPPORT_DENORMAL([x])
IEEE_SUPPORT_DIVIDE([x])
IEEE_SUPPORT_FLAG(flag [, x])[1]
IEEE_SUPPORT_HALTING(flag)[1]
IEEE_SUPPORT_INF([x])
IEEE_SUPPORT_NAN([x])
IEEE_SUPPORT_ROUNDING(round_value [, x])[2]
IEEE_SUPPORT_SQRT([x])
[1] "flag" must be a valid value
[2] "round_value" must be a valid value

Otherwise, the result has the value, false.

Example

IEEE_SUPPORT_STANDARD () has the value false if both IEEE and non-IEEE real kinds are supported.

IEEE_SUPPORT_SUBNORMAL

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE subnormal numbers.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_SUBNORMAL ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for real variables of the same kind type parameter as *x*; otherwise, false.

IEEE_SUPPORT_SUBNORMAL () and IEEE_SUPPORT_SUBNORMAL (0.0_16) return .TRUE. even though Intel® Fortran's implementation does not signal when an underflow results in a REAL (16) subnormal value. Intel® Fortran's implementation does signal when an underflow results in a REAL (16) zero.

Example

IEEE_SUPPORT_SUBNORMAL () has the value true if IEEE subnormal numbers are supported for all real types.

IEEE_SUPPORT_UNDERFLOW_CONTROL

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports the ability to control the underflow mode.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
result = IEEE_SUPPORT_UNDERFLOW_CONTROL ([x])
```

x	(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports controlling the underflow mode for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports controlling the underflow mode for real variables of the same kind type parameter as *x*; otherwise, false.

Example

IEEE_SUPPORT_UNDERFLOW _CONTROL () has the value true if controlling the underflow mode is supported for all real types.

IEEE_UNORDERED

Elemental Module Intrinsic Function (Generic):
Returns whether one or more of the arguments is Not-a-Number (NaN). This is equivalent to the IEEE unordered function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_UNORDERED (x,y)`

x	(Input) Must be of type REAL.
y	(Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if *x* or *y* is a NaN, or both are NaNs; otherwise, false.

Example

IEEE_UNORDERED (0.0, SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

See Also

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_VALUE

Elemental Module Intrinsic Function (Generic):
Creates an IEEE value.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

`result = IEEE_VALUE (x, class)`

x	(Input) Must be of type REAL.
class	(Input) Must be of type TYPE (IEEE_CLASS_TYPE). Its value is one of the following:

IEEE_SIGNALING_NAN	IEEE_NEGATIVE_NORMAL
IEEE_QUIET_NAN	IEEE_POSITIVE_DENORMAL
IEEE_POSITIVE_INF	IEEE_NEGATIVE_DENORMAL
IEEE_NEGATIVE_INF	IEEE_POSITIVE_ZERO
IEEE_POSITIVE_NORMAL	IEEE_NEGATIVE_ZERO

Results

The result type and kind are the same as x. The result value is an IEEE value as specified by "class".

When IEEE_VALUE returns a signaling NaN, it is processor dependent whether or not invalid is signaled and processor dependent whether or not the signaling NaN is converted to a quiet NaN.

Example

IEEE_VALUE (1.0,IEEE_POSITIVE_INF) has the value +infinity.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEOR

Elemental Intrinsic Function (Generic): *Performs an exclusive OR on corresponding bits. This function can also be specified as XOR or IXOR.*

Syntax

```
result = IEOR (i,j)
```

i (Input) Must be of type integer, logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j (Input) Must be of type integer or logical, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer or logical, they must have the same kind type parameter. If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. *i* and *j* must not both be binary, octal, or hexadecimal literal constants.

Results

The result is the same as *i* if *i* is of type integer or logical; otherwise, the result is the same as *j*. If either *i* or *j* is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining *i* and *j* bit-by-bit according to the following truth table:

```
  i   j   IEOR (i, j)
  1   1         0
  1   0         1
  0   1         1
  0   0         0
```

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BIEOR[1]	INTEGER(1)	INTEGER(1)
IIEOR[2]	INTEGER(2)	INTEGER(2)
JIEOR[3]	INTEGER(4)	INTEGER(4)
KIEOR	INTEGER(8)	INTEGER(8)

[1]Or BIXOR

[2]Or HIEOR, HIXOR, or IIXOR

[3]Or JIXOR

Example

IEOR (12, 7) has the value 11; binary 1100 exclusive OR with binary 0111 is binary 1011.

The following shows another example:

```
INTEGER I
I = IEOR(240, 90)  ! returns 170
                   ! IEOR (B'11110000', B'1011010') == B'10101010'
```

The following shows an example using alternate option XOR:

```
INTEGER i, j, k
i = 3              ! B'011'
j = 5              ! B'101'
k = XOR(i, j)      ! returns 6 = B'110'
```

IERRNO

Portability Function: *Returns the number of the last detected error from any routines in the IFPORT module that return error codes.*

Module

USE IFPORT

Syntax

```
result = IERRNO( )
```

Results

The result type is INTEGER(4). The result value is the last error code from any portability routines that return error codes. These error codes are analogous to `errno` on a Linux* system. The module `IFPORT.F90` provides parameter definitions for the following `errno` names (typically found in `errno.h` on Linux systems):

Symbolic name	Number	Description
EPERM	1	Insufficient permission for operation
ENOENT	2	No such file or directory
ESRCH	3	No such process
EIO	5	I/O error
E2BIG	7	Argument list too long
ENOEXEC	8	File is not executable
ENOMEM	12	Not enough resources

Symbolic name	Number	Description
EACCES	13	Permission denied
EXDEV	18	Cross-device link
ENOTDIR	20	Not a directory
EINVAL	22	Invalid argument

The value returned by IERRNO is updated only when an error occurs. For example, if an error occurs on a GETLOG call and then two CHMOD calls succeed, a subsequent call to IERRNO returns the error for the GETLOG call.

Examine IERRNO immediately after returning from a portability routine. IERRNO is set on a per thread basis.

Example

```
USE IFPORT
CHARACTER*20 username
INTEGER(4) ierrval
ierrval=0 !initialize return value
CALL GETLOG(username)
IF (IERRNO( ) == ierrval) then
  print *, 'User name is ',username
  exit
ELSE
  ierrval = ierrno()
  print *, 'Error is ',ierrval
END IF
```

IF - Arithmetic

Statement: *Conditionally transfers control to one of three statements, based on the value of an arithmetic expression. The arithmetic IF statement is a deleted feature in the Fortran Standard. Intel© Fortran fully supports features deleted in the Fortran Standard.*

Syntax

`IF (expr) label1,label2,label3`

expr	Is a scalar numeric expression of type integer or real (enclosed in parentheses).
label1, label2, label3	Are the labels of valid branch target statements that are in the same scoping unit as the arithmetic IF statement.

Description

All three labels are required, but they do not need to refer to three different statements. The same label can appear more than once in the same arithmetic IF statement.

During execution, the expression is evaluated first. Depending on the value of the expression, control is then transferred as follows:

If the Value of *expr* is:	Control Transfers To:
Less than 0	Statement *label1*

If the Value of *expr* is:	Control Transfers To:
Equal to 0	Statement *label2*
Greater than 0	Statement *label3*

Example

The following example transfers control to statement 50 if the real variable `THETA` is less than or equal to the real variable `CHI`. Control passes to statement 100 only if `THETA` is greater than `CHI`.

```
IF (THETA-CHI) 50,50,100
```

The following example transfers control to statement 40 if the value of the integer variable `NUMBER`is even. It transfers control to statement 20 if the value is odd.

```
IF (NUMBER / 2*2 - NUMBER) 20,40,20
```

The following statement transfers control to statement 10 for n < 10, to statement 20 for n = 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 20, 30
```

The following statement transfers control to statement 10 if n <= 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 10, 30
```

See Also

SELECT CASE...END SELECT
Execution Control
Deleted Language Features in the Fortran Standard

IF - Logical

Statement: *Conditionally executes one statement based on the value of a logical expression. (This statement was called a logical IF statement in FORTRAN 77.)*

Syntax

`IF (`*`expr`*`)` *`stmt`*

`expr`	Is a scalar logical expression enclosed in parentheses.
`stmt`	Is any complete, unlabeled, executable Fortran statement, except for the following: • A CASE, DO, IF, FORALL, or WHERE construct • Another IF statement • The END statement for a program, function, or subroutine

When an IF statement is executed, the logical expression is evaluated first. If the value is true, the statement is executed. If the value is false, the statement is not executed and control transfers to the next statement in the program.

Example

The following examples show valid IF statements:

```
IF (J.GT.4 .OR. J.LT.1) GO TO 250

IF (REF(J,K) .NE. HOLD) REF(J,K) = REF(J,K) * (-1.5D0)

IF (ENDRUN) CALL EXIT
```

The following shows another example:

```
   USE IFPORT
   INTEGER(4) istat, errget
   character(inchar)
   real x
   istat = getc(inchar)
   IF (istat) errget = -1
   ...
!   IF (x .GT. 2.3) call new_subr(x)
   ...
```

See Also

IF Construct
Execution Control

IF Clause

Parallel Directive Clause: *Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.*

Syntax

IF ([*directive-name-modifier*:] *scalar-logical-expression*)

directive-name-modifier	Names the associated construct that the IF clause applies to. Currently, you can specify one of the following associated constructs (directives): PARALLEL, SIMD, TARGET DATA, TARGET, TARGET UPDATE, TARGET ENTER DATA, TARGET EXIT DATA, TASK, or TASKLOOP. These directives are only available on Linux* systems: TARGET DATA, TARGET, TARGET UPDATE, TARGET ENTER DATA, TARGET EXIT DATA.
scalar-logical-expression	Must be a scalar logical expression that evaluates to .TRUE. or .FALSE..

At most one IF clause can appear in a non-combined directive. In combined directives, IF clauses with different *directive-name-modifiers* can occur, at most one for each constituent directive making up the combined directive where IF is allowed.

Description

The effect of the IF clause depends on the construct to which it is applied:

- For combined or composite constructs, the IF clause only applies to the semantics of the construct named in the *directive-name-modifier* if one is specified.
- If no *directive-name-modifier* is specified for a combined or composite construct then the IF clause applies to all constructs to which an IF clause can apply.

The following are additional rules that apply to specific OpenMP Fortran directives:

- For the CANCEL OpenMP* Fortran directive, if *scalar-logical-expression* evaluates to false, the construct does not request cancellation. Note that *directive-name-modifier* cannot specify CANCEL.
- For the PARALLEL OpenMP Fortran directive:
  - The enclosed code section is executed in parallel only if *scalar-logical-expression* evaluates to .TRUE.. Otherwise, the parallel region is serialized. If this clause is not used, the region is executed as if an IF(.TRUE.) clause were specified.
  - This clause is evaluated in the context outside of this construct.
- For the SIMD OpenMP Fortran directive, if *scalar-logical-expression* evaluates to .FALSE., the number of iterations to be executed concurrently is one.
- For the TARGET OpenMP Fortran directive, if *scalar-logical-expression* evaluates to .FALSE., the target region is not executed by the device. It is executed by the encountering task.
- For the TARGET DATA OpenMP Fortran directive, if *scalar-logical-expression* evaluates to .FALSE., the new device data environment is not created.
- For the TARGET UPDATE OpenMP Fortran directive, if *scalar-logical-expression* evaluates to .FALSE., the TARGET UPDATE directive is ignored.
- For the TASK OpenMP Fortran directive:
  - If *scalar-logical-expression* evaluates to .FALSE., the encountering thread must suspend the current task region and begin execution of the generated task immediately. The suspended task region will not be resumed until the generated task is completed.
  - This clause is evaluated in the context outside of this construct.

IF Construct

Statement: *Conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. (This construct was called a block IF statement in FORTRAN 77.)*

Syntax

```
[name:] IF (expr) THEN
    block
[ELSE IF (expr) THEN [name]
   block]
[ELSE [name]
   block]
END IF [name]
```

name	(Optional) Is the name of the IF construct.
expr	Is a scalar logical expression enclosed in parentheses.
block	Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an IF THEN statement, the same name must appear in the corresponding END IF statement. If a construct name is specified on an ELSE IF or ELSE statement, the same name must appear in the corresponding IF THEN and END IF statements.

The same construct name must not be used for different named constructs in the same scoping unit.

Depending on the evaluation of the logical expression, one block or no block is executed. The logical expressions are evaluated in the order in which they appear, until a true value is found or an ELSE or END IF statement is encountered.

Once a true value is found or an ELSE statement is encountered, the block immediately following it is executed and the construct execution terminates.

If none of the logical expressions evaluate to true and no ELSE statement appears in the construct, no block in the construct is executed and the construct execution terminates.

NOTE

No additional statement can be placed after the IF THEN statement in a block IF construct. For example, the following statement is invalid in the block IF construct:

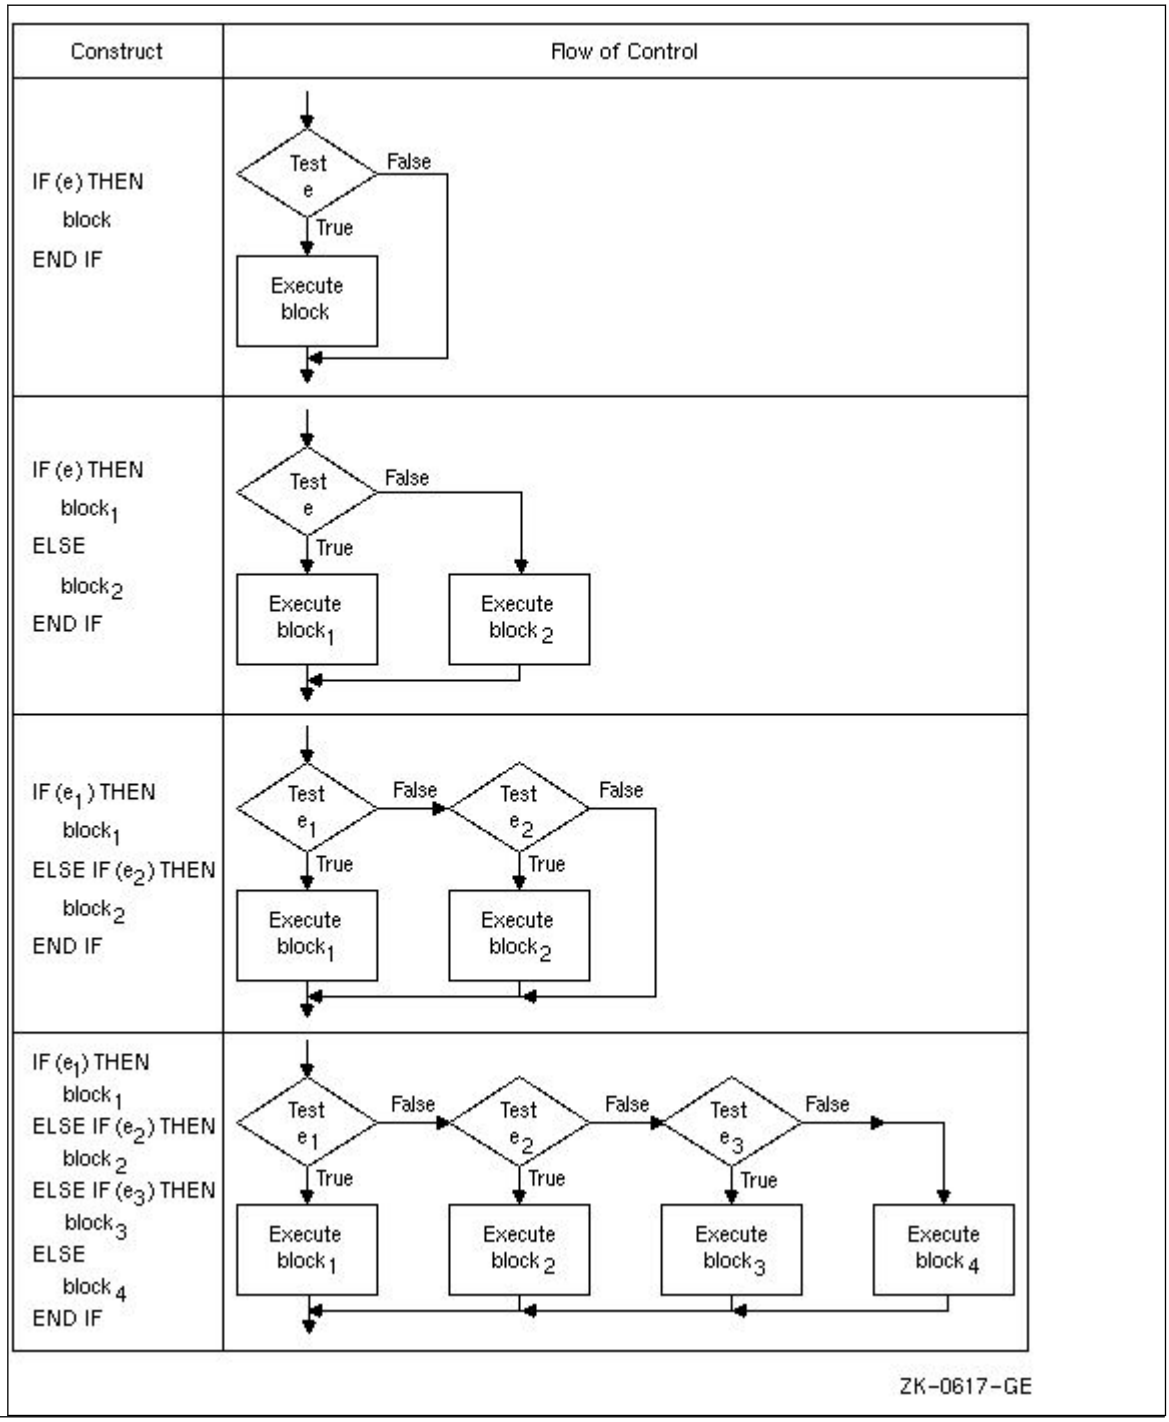
```
IF (e) THEN I = J
```

This statement is translated as the following logical IF statement:

```
IF (e) THENI = J
```

You cannot use branching statements to transfer control to an ELSE IF statement or ELSE statement. However, you can branch to an END IF statement from within the IF construct.

The following figure shows the flow of control in IF constructs:



You can include an IF construct in the statement block of another IF construct, if the nested IF construct is completely contained within a statement block. It cannot overlap statement blocks.

Example

The following example shows the simplest form of an IF construct:

```
Form                  Example
  IF (expr) THEN        IF (ABS(ADJU) .GE. 1.0E-6) THEN
    block                 TOTERR = TOTERR + ABS(ADJU)
                          QUEST = ADJU/FNDVAL
  END IF                END IF
```

This construct conditionally executes the block of statements between the IF THEN and the END IF statements.

The following shows another example:

```
!  Simple block IF:
   IF (i .LT. 10) THEN
      ! the next two statements are only executed if i < 10
      j = i
      slice = TAN (angle)
   END IF
```

The following example shows a named IF construct:

```
  BLOCK_A: IF (D > 0.0) THEN        ! Initial statement for named construct

    RADIANS = ACOS(D)               ! These two statements
    DEGREES = ACOSD(D)              !       form a block

  END IF BLOCK_A                    ! Terminal statement for named construct
```

The following example shows an IF construct containing an ELSE statement:

```
Form                  Example
  IF (expr) THEN        IF (NAME .LT. 'N') THEN
    block1                IFRONT = IFRONT + 1
                          FRLET(IFRONT) = NAME(1:2)
  ELSE                  ELSE
    block2                IBACK = IBACK + 1
  END IF                END IF
```

Block1 consists of all the statements between the IF THEN and ELSE statements. Block2 consists of all the statements between the ELSE and the END IF statements.

If the value of the character variable NAME is less than `'N '`, block1 is executed. If the value of NAME is greater than or equal to `'N '`, block2 is executed.

The following example shows an IF construct containing an ELSE IF THEN statement:

```
Form                    Example
    IF (expr) THEN          IF (A .GT. B) THEN
    block1                  D = B
                            F = A - B
  ELSE IF (expr) THEN     ELSE IF (A .GT. B/2.) THEN
    block2                  D = B/2.
                            F = A - B/2.
  END IF                  END IF
```

If A is greater than B, block1 is executed. If A is not greater than B, but A is greater than B/2, block2 is executed. If A is not greater than B and A is not greater than B/2, neither block1 nor block2 is executed. Control transfers directly to the next executable statement after the END IF statement.

The following shows another example:

```
!  Block IF with ELSE IF statements:

   IF (j .GT. 1000) THEN
      ! Statements here are executed only if J > 1000
   ELSE IF (j .GT. 100) THEN
      ! Statements here are executed only if J > 100 and j <= 1000
   ELSE IF (j .GT. 10) THEN
      ! Statements here are executed only if J > 10 and j <= 100
   ELSE
      ! Statements here are executed only if j <= 10
   END IF
```

The following example shows an IF construct containing several ELSE IF THEN statements and an ELSE statement:

```
Form                      Example
  IF (expr) THEN            IF (A .GT. B) THEN
    block1                    D = B
                              F = A - B
  ELSE IF (expr) THEN       ELSE IF (A .GT. C) THEN
    block2                    D = C
                              F = A - C
  ELSE IF (expr) THEN       ELSE IF (A .GT. Z) THEN
    block3                    D = Z
                              F = A - Z
  ELSE                      ELSE
    block4                    D = 0.0
                              F = A
  END IF                    END IF
```

If A is greater than B, block1 is executed. If A is not greater than B but is greater than C, block2 is executed. If A is not greater than B or C but is greater than Z, block3 is executed. If A is not greater than B, C, or Z, block4 is executed.

The following example shows a nested IF construct:

```
Form                      Example
  IF (expr) THEN            IF (A .LT. 100) THEN
    block1                    INRAN = INRAN + 1
    IF (expr2) THEN           IF (ABS(A-AVG) .LE. 5.) THEN
      block1a                   INAVG = INAVG + 1
    ELSE                      ELSE
      block1b                   OUTAVG = OUTAVG + 1
    END IF                    END IF
  ELSE                      ELSE
    block2                    OUTRAN = OUTRAN + 1
  END IF                    END IF
```

If A is less than 100, the code immediately following the IF is executed. This code contains a nested IF construct. If the absolute value of A minus AVG is less than or equal to 5, block1a is executed. If the absolute value of A minus AVG is greater than 5, block1b is executed.

If A is greater than or equal to 100, block2 is executed, and the nested IF construct (in block1) is not executed.

The following shows another example:

```
!  Nesting of constructs and use of an ELSE statement following
!  a block IF without intervening ELSE IF statements:
   IF (i .LT. 100) THEN
```

```
    ! Statements here executed only if i < 100
    IF (j .LT. 10) THEN
    ! Statements here executed only if i < 100 and j < 10
    END IF
    ! Statements here executed only if i < 100
  ELSE
    ! Statements here executed only if i >= 100
    IF (j .LT. 10) THEN
    ! Statements here executed only if i >= 100 and j < 10
    END IF
    ! Statements here executed only if i >= 100
  END IF
```

IF Directive Construct

General Compiler Directive: *A conditional compilation construct that begins with an IF or IF DEFINED directive. IF tests whether a logical expression is .TRUE. or .FALSE.. IF DEFINED tests whether a symbol has been defined.*

Syntax

```
!DIR$ IF (expr) -or- !DIR$ IF DEFINED (name)
   block
[!DIR$ ELSEIF (expr)
   block] ...
[!DIR$ ELSE
   block]
!DIR$ ENDIF
```

expr	Is a logical expression that evaluates to .TRUE. or .FALSE..
name	Is the name of a symbol to be tested for definition.
block	Are executable statements that are compiled (or not) depending on the value of logical expressions in the IF directive construct.

The IF and IF DEFINED directive constructs end with an ENDIF directive and can contain one or more ELSEIF directives and at most one ELSE directive. If the logical condition within a directive evaluates to .TRUE. at compilation, and all preceding conditions in the IF construct evaluate to .FALSE., then the statements contained in the directive block are compiled.

A *name* can be defined with a DEFINE directive, and can optionally be assigned an integer value. If the symbol has been defined, with or without being assigned a value, IF DEFINED (name) evaluates to .TRUE.; otherwise, it evaluates to .FALSE..

If the logical condition in the IF or IF DEFINED directive is .TRUE., statements within the IF or IF DEFINED block are compiled. If the condition is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If the logical expression in an ELSEIF directive is .TRUE., statements within the ELSEIF block are compiled. If the expression is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If control reaches an ELSE directive because all previous logical conditions in the IF construct evaluated to .FALSE., the statements in an ELSE block are compiled unconditionally.

You can use any Fortran logical or relational operator or symbol in the logical expression of the directive, including: .LT., <, .GT., >, .EQ., ==, .LE., <=, .GE., >=, .NE., /=, .EQV., .NEQV., .NOT., .AND., .OR., and .XOR.. The logical expression can be as complex as you like, but the whole directive must fit on one line.

Example

```
!  When the following code is compiled and run,
!  the output is:
!  Or this compiled if all preceding conditions .FALSE.
!
!DIR$ DEFINE flag=3
!DIR$ IF (flag .LT. 2)
   WRITE (*,*) "This is compiled if flag less than 2."
!DIR$ ELSEIF (flag >= 8)
   WRITE (*,*) "Or this compiled if flag greater than &
                or equal to 8."
!DIR$ ELSE
   WRITE (*,*) "Or this compiled if all preceding &
                conditions .FALSE."
!DIR$ ENDIF
END
```

IF Construct
General Compiler Directives
Syntax Rules for Compiler Directives

IF DEFINED Directive

Statement: *Marks the start of an IF Directive Construct.*

See Also

See IF Directive Construct.

IFIX

Elemental Intrinsic Function (Generic): *Converts a single-precision real argument to an integer by truncating.*

See Also

See INT.

IFLOATI, IFLOATJ

Portability Functions: *Convert an integer to single-precision real type.*

Module

USE IFPORT

Syntax

```
result = IFLOATI (i)
```

```
result = IFLOATJ (j)
```

i	(Input) Must be of type INTEGER(2).
j	(Input) Must be of type INTEGER(4).

Results

The result type is single-precision real (REAL(4) or REAL*4).

See Also

DFLOAT

ILEN

Inquiry Intrinsic Function (Generic): *Returns the length (in bits) of the two's complement representation of an integer.*

Syntax

```
result = ILEN (i)
```

i	Must be of type integer.

Results

The result type and kind are the same as *i*. The result value is (LOG_2(*i*+ 1)) if *i* is not negative; otherwise, the result value is (LOG_2(- *i*)).

Example

ILEN (4) has the value 3.

ILEN (-4) has the value 2.

IMAGE_INDEX

Transformational Intrinsic Function (Generic): *Converts cosubscripts to an image index.*

Syntax

```
result = IMAGE_INDEX (coarray, sub)
result = IMAGE_INDEX (coarray, sub, team)
result = IMAGE_INDEX (coarray, sub, team_number)
```

coarray	(Input) Must be a coarray; it can be of any type.
sub	(Input) Must be a rank-one integer array of size equal to the corank of *coarray*.
team	(Input) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV. Its value must identify the current or an ancestor team.
team_number	(Input) Must be an integer scalar. It must identify the initial team (-1) or a team formed by the same execution of the FORM TEAM statement that created the current team (a sibling team of the current team).

Results

The result is default integer scalar. The result is the index of the corresponding image if the value of *sub* is a valid sequence of cosubscripts for *coarray* on the team specified by *team* or *team_number*, or for the current team if neither *team* nor *team_number* is specified. Otherwise, the result is zero.

Examples

If coarray D is declared as D [0:*] and coarray C is declared as C(5,10) [10, 0:9, 0:*], IMAGE_INDEX (D, [0]) has the value 1 and IMAGE_INDEX (C, [3, 1, 2]) has the value 213 (on any image).

Consider the following program:

```
PROGRAM main
USE, INTRINSIC       :: ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)     :: initial, odd_even
REAL                 :: ca1[4:*], ca2[2, *]
INTEGER              :: i, j, k, l
initial = GET_TEAM (CURRENT_TEAM)
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
PRINT *, THIS_IMAGE()
PRINT *, THIS_IMAGE (coarray1)
PRINT *, THIS_IMAGE (coarray2, 2)
CHANGE TEAM (odd_even)
  . . .
  i = IMAGE_INDEX(ca1, [6], 2)
  j = IMAGE_INDEX(ca1, [6], 1)
  k = IMAGE_INDEX(ca2, [2, 4], initial)
  l = IMAGE_INDEX(ca1, [12], -1)
  . . .
END TEAM
. . .
END PROGRAM
```

If there are 10 images on the initial team, ca1[4] will be on image 1, ca1[5] on image 2, and ca1[13] will be on image 10. Similarly, ca2[1, 1] will be on image 1, ca[2, 1] on image 2, ending with ca2[2, 5] will be on image 10. The FORM TEAM statement divides the images into two teams, with team 1 having images [1, 3, 5, 7, 9] with image numbers [1, 2, 3, 4, 5] respectively, and team 2 having images [2, 4, 6, 8, 10] with image numbers [1, 2, 3, 4, 5] respectively.

After the 4 calls to IMAGE_INDEX, the value of i will be zero (ca1[6] is not on an image in team 2), j will have the value 2, k will have the value 8, and l will have the value 9. Note that the team number -1 always refers to the initial team. Note also that if the FORM TEAM does not specify NEW_INDEX, the image numbers on the new teams formed by the FORM TEAM are assigned in a processor-dependent manner.

See Also

FORM TEAM

IMAGE_STATUS

Elemental Intrinsic Function (Generic): *Returns the execution status value of the specified image.*

Syntax

`result = IMAGE_STATUS (image [, team])`

image	(Input) Must be a positive integer with a value equal to or less than the number of executing images on the specified team.

team	(Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.

Results

The result type is default integer. If *image* on the specified *team* has initiated normal termination, the result is the value STAT_STOPPED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. If *image* on the specified *team* has failed, the result is the value STAT_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. Otherwise, the result value is zero.

Example

If image 5 on the specified team has initiated normal termination, and image 12 on the specified team is known to have failed, then IMAGE_STATUS (5) returns the value STAT_STOPPED_IMAGE and IMAGE_STATUS (12) returns the value STAT_FAILED_IMAGE. If image 3 on the specified team has neither initiated normal termination nor failed, IMAGE_STATUS (3) returns the value zero.

IMPLICIT

Statement: *Overrides the default implicit typing rules for names. (The default data type is default INTEGER kind for names beginning with the letters I through N, and default REAL kind for names beginning with any other letter.) An IMPLICIT NONE statement overrides all implicit typing in a scoping unit, or it indicates that all dummy procedures and externals must explicitly be given the external attribute.*

Syntax

The IMPLICIT statement takes one of the following forms:

```
IMPLICIT type(a[,a]...)[,type(a[,a]...)]...
IMPLICIT NONE [(spec-list])
```

type	Is a data type specifier (CHARACTER*(*) is not allowed).
a	Is a single letter, a dollar sign ($),or a range of letters in alphabetical order. The form for a range of letters is a_1-a_2, where the second letter follows the first alphabetically (for example, A-C).
spec	Is TYPE or EXTERNAL. The keyword must appear in parentheses. If more than one keyword is present, they must be separated by commas.

The dollar sign can be used at the end of a range of letters, since IMPLICIT interprets the dollar sign to alphabetically follow the letter Z. For example, a range of X-$ would apply to identifiers beginning with the letters X, Y, Z, or $.

In Intel® Fortran, the parentheses around the list of letters are optional.

Description

The IMPLICIT statement assigns the specified data type (and kind parameter) to all names that have no explicit data type and begin with the specified letter or range of letters. It has no effect on the default types of intrinsic procedures.

When the data type is CHARACTER*len, *len* is the length for character type. The *len* is an unsigned integer constant or an integer specification expression enclosed in parentheses. The range for *len* is 1 to 2**31-1 on IA-32 architecture; 1 to 2**63-1 on Intel® 64 architecture.

Names beginning with a dollar sign ($) are implicitly INTEGER.

The IMPLICIT NONE statement disables all implicit typing defaults. When IMPLICIT NONE is used, all names in a program unit must be explicitly declared. An IMPLICIT NONE statement must precede any PARAMETER statements, and there must be no other IMPLICIT statements in the scoping unit. An IMPLICIT NONE (TYPE) statement is the same as an IMPLICIT NONE statement. If an IMPLICIT NONE (EXTERNAL) statement appears in a scoping unit, all dummy procedures and external procedures in that scope or a contained scope of BLOCK must have an accessible explicit interface or be declared EXTERNAL.

NOTE
To receive diagnostic messages when variables are used but not declared, you can specify compiler option warn declarations instead of using IMPLICIT NONE or IMPLICIT NONE (TYPE). To receive diagnostic messages when external and dummy procedures have not explicitly been given the EXTERNAL attribute, you can specify compiler option `warn externals` instead of using IMPLICIT NONE (EXTERNAL).

The following IMPLICIT statement represents the default typing as specified by the Fortran Standard for names when they are not explicitly typed:

```
IMPLICIT INTEGER (I-N), REAL (A-H, O-Z)
```

Example

The following are examples of the IMPLICIT statement:

```
IMPLICIT DOUBLE PRECISION (D) IMPLICIT COMPLEX (S,Y), LOGICAL(1) (L,A-C)
IMPLICIT CHARACTER*32 (T-V)
IMPLICIT CHARACTER*2 (W)
IMPLICIT TYPE(COLORS) (E-F), INTEGER (G-H)
IMPLICIT NONE (EXTERNALS, TYPE)    ! Must be the only IMPLICIT statement in a scoping unit
```

The following shows another example:

```
SUBROUTINE FF (J)
IMPLICIT INTEGER (a-b), CHARACTER*(J+1) (n), TYPE(fried) (c-d)
TYPE fried
INTEGER e, f
REAL g, h
END TYPE
age = 10 ! integer
name = 'Paul' ! character
c%e = 1 ! type fried, integer component
```

IMPORT

Statement: *Controls accessibility of host entities in a submodule, module procedure, a contained procedure, a block construct, or in the interface body of an interface block.*

Syntax

The IMPORT statement takes the following form:

```
IMPORT [[::] import-name-list]
```

```
IMPORT,ONLY: import-name-list
```

```
IMPORT,NONE
```

```
IMPORT,ALL
```

import-name-list	(Input) Is the name of one or more entities accessible in the host scoping unit.

An IMPORT statement can appear in a submodule, module procedure, a contained procedure, the specification part of a BLOCK construct, or in an interface body. It can not appear in the specification part of a main program, external procedure, module, or block data except in an interface body.

An IMPORT statement must appear after any USE statements, and before any other specification statements. Each of the named entities must be an accessible entity in the host scoping unit. Within an interface body each named entity must be explicitly declared before the interface body, or accessible by use or host association in the host containing the IMPORT statement.

If IMPORT, ONLY appears within a scoping unit, all other IMPORT statements in that scoping unit must be IMPORT, ONLY statements. An entity is host associated in a scoping unit which contains an IMPORT, ONLY statement if it appears in an *import-name-list* in that scoping unit.

If IMPORT, NONE is specified, no entities in the host are accessible by host association in that scoping unit. This is the default behavior for interface bodies for a dummy or external procedure. IMPORT, NONE must not appear in the specification part of a submodule.

If an IMPORT, ALL or an IMPORT, NONE statement appears in a scoping unit, it must be the only IMPORT statement in that scoping unit.

If *import-name-list* is not specified, and if ALL, ONLY, or NONE are not specified, all of the accessible named entities in the host scoping unit are imported unless they are made inaccessible by an entity of the same name in the local scope. This is the default behavior for a nested scoping unit, other than an interface body, for a dummy or external procedure.

If IMPORT, ALL is specified, all entities in the host are accessible by host association. If an entity is made accessible by an IMPORT, ALL statement or by its name appearing in an *import-name-list*, it cannot be made inaccessible by declaring another entity with the same name in the local scope.

If an IMPORT statement with an *import-name-list* appears, only the named entities are available by host association.

Examples

The following examples show how the IMPORT statement can be applied.

```
module mymod
type mytype
  integer comp
end type mytype
interface
  subroutine sub (arg)
    import
```

```
    type(mytype) :: arg
  end subroutine sub
end interface
end module mymod

module host
  integer  :: i, j, k
  contains
  subroutine sub1 ()
    import :: i, j
    k = i + j      ! only i and j are host associated, k is local to sub1
  end subroutine
  subroutine sub2 ()
    import, none
    k = i + j      ! i, j, and k are local to sub2
  end subroutine
  subroutine sub3 ()
    import all
    k = i + j      ! i, j, and k are all host associated
  end subroutine
  subroutine sub4 ()
    import, only : i
    import, only : j
    k = i + j      ! i and j are host associated, k is local
  end subroutine
end module
```

IMPURE

Keyword: *Asserts that a user-defined procedure has side effects.*

Description

This kind of procedure is specified by using the prefix IMPURE in a FUNCTION or SUBROUTINE statement. By default all user-defined procedures are impure, that is, they are allowed to have side effects, except for elemental procedures, which are by default PURE.

An IMPURE elemental procedure has the restrictions that apply to elemental procedures, but it does not have any of the restrictions of PURE elemental procedures.

An impure elemental procedure can have side effects and it can contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement or an ERROR STOP statement
- An image control statement

An impure elemental procedure cannot be referenced in a context that requires a procedure to be pure; for example:

- It cannot be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It cannot be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, or finalization.
- It cannot be passed as an actual argument to a pure procedure.

Example

```
module my_rand_mod
integer, save :: my_rand_seed (8)

  contains
    impure elemental subroutine my_rand (r)

    ! my_rand updates module variable my_rand_seed (an array)
    ! and returns the next value of a "pseudo" random sequence in
    ! output dummy argument r

      real, intent(out) :: r

      ! code goes here

    end subroutine my_rand
end module my_rand_mod
```

FUNCTION
SUBROUTINE

IN_REDUCTION

Parallel Directive Clause: *Specifies that a task participates in a reduction. The IN_REDUCTION clause is a reduction participating clause.*

Syntax

IN_REDUCTION (*reduction-identifier* : *list*)

reduction identifier and *list*	These are defined in the REDUCTION clause description. All the common restrictions for the REDUCTION clause apply to the IN_REDUCTION clause.

A *list* item that appears in an IN_REDUCTION clause must appear in a TASK_REDUCTION clause or a REDUCTION clause with the TASK reduction modifier. The construct associated with the innermost region that meets this condition must specify the same *reduction-identifier* as the IN_REDUCTION clause.

If the IN_REDUCTION clause appears in a TARGET construct, the target task becomes the task participating in the reduction. A private copy of each *list* item is created in the data environment of the target task. The copy is implicitly mapped into the data environment of the target device if the target device is not the parent device.

If the IN_REDUCTION clause is associated with a TASK construct, the generated task is the participating task, and a private copy of each *list* item may be created.

At the end of the region, the value of private copies of list items are combined with the value of a private copy created by a *reduction scoping clause*, and finally with the original list item.

The *list* items specified in an IN_REDUCTION clause must match the *list* items that appear in a TASK_REDUCTION clause or in a REDUCTION clause with the TASK reduction modifier. The construct specifying the TASK_REDUCTION or REDUCTION clause corresponds to a region in which the participating task's region is closely nested. The innermost enclosing construct that meets this condition must also specify the same *reduction-identifier* specified in the IN_REDUCTION clause.

In the following example, the IN_REDUCTION clause at (3) must name the same operator (+) and variable (a) as in the TASK_REDUCTION clause in (2). The IN_REDUCTION clause at (4) must name the same operator (*) and variable (a) as in the TASK_REDUCTION clause in (1).

```
!$omp taskgroup task_reduction(*:a)       ! (1) *:a
    ...
!$omp taskgroup task_reduction(+:a)       ! (2) +:a
!$omp task in_reduction(+:a)              ! (3) +:a matches (2)
    a = a + x
!$omp end task                            ! ends (3) +:a
    ...
!$omp end taskgroup                          ! ends (2) +:a
    ...
!$omp task in_reduction(*:a)              ! (4) *:a matches (1)
    a = a * y
!$omp end task                            ! ends (4) *:a
!$omp end taskgroup                          ! ends (1) *:a
```

TASK
TASKLOOP

INCLUDE

Statement: *Directs the compiler to stop reading statements from the current file and read statements in an included file or text module.*

Syntax

The INCLUDE line takes the following form:

```
INCLUDE 'filename[/[NO]LIST]'
```

filename	Is a character string specifying the name of the file to be included; it must not be a named constant. The form of the file name must be acceptable to the operating system, as described in your system documentation.
[NO]LIST	Specifies whether the incorporated code is to appear in the compilation source listing. In the listing, a number precedes each incorporated statement. The number indicates the "include" nesting depth of the code. The default is /NOLIST. /LIST and /NOLIST must be spelled completely. You can only use /[NO]LIST if you specify compiler option vms (which sets OpenVMS defaults).

Description

An INCLUDE line can appear anywhere within a scoping unit. The line can span more than one source line, but no other statement can appear on the same line. The source line cannot be labeled.

An included file or text module cannot begin with a continuation line, and each Fortran statement must be completely contained within a single file.

An included file or text module can contain any source text, but it cannot begin or end with an incomplete Fortran statement.

The included statements, when combined with the other statements in the compilation, must satisfy the statement-ordering restrictions shown in Statements.

Included files or text modules can contain additional INCLUDE lines, but they must not be recursive. INCLUDE lines can be nested until system resources are exhausted.

When the included file or text module completes execution, compilation resumes with the statement following the INCLUDE line.

You can use modules instead of include files to achieve encapsulation of related data types and procedures. For example, one module can contain derived type definitions as well as special operators and procedures that apply to those types. For information on how to use modules, see Program Units and Procedures.

Example

In the following example, a file named COMMON.FOR (in the current working directory) is included and read as input.

Including Text from a File

Main Program File

```
PROGRAM
  INCLUDE 'COMMON.FOR'
  REAL, DIMENSION(M) :: Z
  CALL CUBE
  DO I = 1, M
    Z(I) = X(I) + SQRT(Y(I))
    ...
  END DO
END

SUBROUTINE CUBE
  INCLUDE 'COMMON.FOR'
  DO I=1,M
    X(I) = Y(I)**3
  END DO
  RETURN
END
```

COMMON.FOR File

```
INTEGER, PARAMETER :: M=100
REAL, DIMENSION(M) :: X, Y
COMMON X, Y
```

The file COMMON.FOR defines a named constant M, and defines arrays X and Y as part of blank common.

The following example program declares its common data in an include file. The contents of the file INCLUDE.INC are inserted in the source code in place of every INCLUDE 'INCLUDE.INC' line. This guarantees that all references to common storage variables are consistent.

```
INTEGER i
REAL x
INCLUDE 'INCLUDE.INC'

DO i = 1, 5
  READ (*, '(F10.5)') x
  CALL Push (x)
END DO
```

USE

INDEX

Elemental Intrinsic Function (Generic): *Returns the starting position of a substring within a string.*

Syntax

```
result = INDEX (string, substring [,back] [, kind])
```

string	(Input) Must be of type character.
substring	(Input) Must be of type character.
back	(Input; optional) Must be of type logical.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *back* does not appear (or appears with the value false), the value returned is the minimum value of I such that *string*(I : I + LEN (*substring*) - 1) = *substring*(or zero if there is no such value). If LEN (*string*) < LEN (*substring*), zero is returned. If LEN (*substring*) = zero, 1 is returned.

If *back* appears with the value true, the value returned is the maximum value of I such that *string*(I : I + LEN (*substring*) - 1) = *substring* (or zero if there is no such value). If LEN(*string*) < LEN (*substring*), zero is returned. If LEN (*substring*) = zero, LEN (*string*) + 1 is returned.

Specific Name	Argument Type	Result Type
	CHARACTER	INTEGER(1)
	CHARACTER	INTEGER(2)
INDEX [1]	CHARACTER	INTEGER(4)
	CHARACTER	INTEGER(8)

[1]The setting of compiler options specifying integer size can affect this function.

Example

INDEX ('FORTRAN', 'O', BACK = .TRUE.) has the value 2.

INDEX ('XXXX', " ", BACK = .TRUE.) has the value 5.

The following shows another example:

```
I = INDEX('banana','an', BACK = .TRUE.) ! returns 4
I = INDEX('banana', 'an') ! returns 2
```

SCAN

INLINE, FORCEINLINE, and NOINLINE

General Compiler Directives: *Tell the compiler to perform the specified inlining on routines within statements or DO loops.*

Syntax

```
!DIR$ INLINE [RECURSIVE]
!DIR$ FORCEINLINE [RECURSIVE]
!DIR$ NOINLINE
```

The INLINE directive specifies that the routines can be inlined.

The FORCEINLINE directive specifies that a routine should be inlined whenever the compiler can do so. This condition can also be specified by using compiler option `[Q]inline-forceinline`.

The NOINLINE directive specifies that a routine should not be inlined.

These directives apply only to the immediately following statement or DO construct. All statements within the immediately following DO construct are affected.

If keyword RECURSIVE is specified, the specified inlining is performed when the routine calls itself directly or indirectly.

The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

Caution
When you use directive FORCEINLINE, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Example

Consider the following:

```
!DIR$ INLINE
A = F(B) + G(C)  ! inline the call to function F and inline the call to function G

!DIR$ INLINE
   DO I = 1, N
      CALL F1 ( G1(A), G2(A)) ! inline the call to F1 and the function executions of G1 and G2
      !DIR$ NOINLINE
         DO J = 1, M
            M(J) = F (M(J))   ! do not inline this call to F {M is a data array}
         END DO
      M(I) = F2 (X)           ! F2 gets inlined from the directive before DO I

      !DIR$ FORCEINLINE RECURSIVE
      CALL F3 ()       ! F3 must be inlined and it calls itself recursively so inline those
calls too
   END DO
```

INMAX

Portability Function: *Returns the maximum positive value for an integer.*

Module

USE IFPORT

Syntax

```
result = INMAX (i)
```

i (Input) INTEGER(4).

Results

The result type is INTEGER(4). The result is the maximum 4-byte signed integer value for the argument.

INQUIRE

Statement: *Returns information on the status of specified properties of a file, logical unit, or directory. It takes one of the following forms:*

Syntax

Inquiring by File:

```
INQUIRE (FILE=name[, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, SIZE=sz] [, IOSTAT=i-var] [, DEFAULTFILE=def] slist)
```

Inquiring by Unit:

```
INQUIRE ([UNIT=]io-unit [, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, SIZE=sz] [, IOSTAT=i-var] slist)
```

Inquiring by Directory:

```
INQUIRE (DIRECTORY=dir, EXIST=ex [, DIRSPEC=dirspec] [, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, SIZE=sz] [, IOSTAT=i-var])
```

Inquiring by Output List:

```
INQUIRE (IOLENGTH=len) out-item-list
```

name Is a scalar default character expression specifying the name of the file for inquiry. For more information, see FILE Specifier and STATUS Specifier.

label Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

id-var Is a scalar integer expression identifying a data transfer operation that was returned using the ID= specifier in a previous asynchronous READ or WRITE statement. For more information, see ID Specifier.

msg-var Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

sz Is a scalar integer variable that is assigned the size of the file in file storage units. For more information, see Size Specifier.

i-var

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. For more information, see I/O Status Specifier.

def

Is a scalar default character expression specifying a default file pathname string. (For more information, see the DEFAULTFILE specifier.)

slist

Is one or more of the following inquiry specifiers (each specifier can appear only once):

ACCESS	DELIM	NEXTREC	RECL
ACTION	DIRECT	NUMBER	RECORDTYPE
ASYNCHRONOUS	ENCODING	OPENED	ROUND
BINARY	EXIST	ORGANIZATION	SEQUENTIAL
BLANK	FORM	PAD	SHARE
BLOCKSIZE	FORMATTED	PENDING	SIGN
BUFFERED	IOFOCUS	POS	SIZE
CARRIAGECONTROL	MODE	POSITION	UNFORMATTED
CONVERT	NAME	READ	WRITE
DECIMAL	NAMED	READWRITE	

io-unit

Is an external unit specifier.

The unit does not have to exist, nor does it need to be connected to a file. If the unit is connected to a file, the inquiry encompasses both the connection and the file.

dir

Is a scalar default character expression specifying the name of the directory for inquiry. If you are inquiring by directory, it must be present.

ex

Is a scalar default logical variable that is assigned the value .TRUE. if *dir* names a directory that exists; otherwise, *ex* is assigned the value .FALSE.. If you are inquiring by directory, it must be present. For more information, see the EXIST Specifier.

dirspec

Is a scalar default character variable that is assigned the value of the full directory specification of *dir* if *ex* is assigned the value .TRUE.. This specifier can only be used when inquiring by directory.

len

(Output) Is a scalar integer variable that is assigned a value corresponding to the length of an unformatted, direct-access record resulting from the use of the *out-item-list* in a WRITE statement.

The value is suitable to use as a RECL specifier value in an OPEN statement that connects a file for unformatted, direct access.

The unit of the value is 4-byte longwords, by default. However, if you specify compiler option assume byterecl, the unit is bytes.

out-item-list (Output) Is a list of one or more output items (see I/O Lists).

Description

The control specifiers ([UNIT=] *io-unit*, ERR= *label*, and IOSTAT= *i-var*) and inquiry specifiers can appear anywhere within the parentheses following INQUIRE. However, if the UNIT keyword is omitted, the *io-unit* must appear first in the list.

An INQUIRE statement can be executed before, during, or after a file is connected to a unit. The specifier values returned are those that are current when the INQUIRE statement executes.

To get file characteristics, specify the INQUIRE statement after opening the file.

Examples

The following shows examples of INQUIRE statements.

In the last statement, you can use the length returned in LEN as the value for the RECL specifier in an OPEN statement that connects a file for unformatted direct access. If you have already specified a value for RECL, you can check LEN to verify that A and B are less than or equal to the record length you specified.

```
INQUIRE (FILE='FILE_B', EXIST=EXT)
INQUIRE (4, FORM=FM, IOSTAT=IOS, ERR=20)
INQUIRE (IOLENGTH=LEN) A, B
```

In the following example, the program prompts for the name of a data file. The INQUIRE statement then determines whether the file exists. If it does not, the program prompts for another file name.

```
      CHARACTER*12 fname
      LOGICAL exists

!     Get the name of a file:
100   WRITE (*, '(1X, A\)') 'Enter the file name: '
      READ (*, '(A)') fname

!     INQUIRE about file's existence:
      INQUIRE (FILE = fname, EXIST = exists)

      IF (.NOT. exists) THEN
        WRITE (*,'(2A/)') ' >> Cannot find file ', fname
        GOTO 100
      END IF
      END
```

INT

Elemental Intrinsic Function (Generic): *Converts a value to integer type.*

Syntax

```
result = INT (a[,kind])
```

a	(Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of *a* as follows:

- If *a* is of type integer, INT(*a*) = *a*.
- If *a* is of type real and | *a* | < 1, INT(*a*) has the value zero.

  If *a* is of type real and | *a* | >=1, INT(*a*) is the integer whose magnitude is the largest integer that does not exceed the magnitude of *a* and whose sign is the same as the sign of *a*.
- If *a* is of type complex, INT(*a*) is the value obtained by applying the preceding rules (for a real argument) to the real part of *a*.
- If *a* is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of *a* as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by *a* is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by *a* is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1), INTEGER(2), INTEGER(4)	INTEGER(4)
	INTEGER(1), INTEGER(2), INTEGER(4), INTEGER(8)	INTEGER(8)
IJINT	INTEGER(4)	INTEGER(2)
IIFIX[2]	REAL(4)	INTEGER(2)
IINT	REAL(4)	INTEGER(2)
IFIX [3, 4]	REAL(4)	INTEGER(4)

Specific Name [1]	Argument Type	Result Type
JFIX	INTEGER(1), INTEGER(2), INTEGER(4),	INTEGER(4)
	INTEGER(8), REAL(4), REAL(8), REAL(16),	
	COMPLEX(4), COMPLEX(8), COMPLEX(16)	
INT [5, 6, 7]	REAL(4)	INTEGER(4)
KIFIX	REAL(4)	INTEGER(8)
KINT	REAL(4)	INTEGER(8)
IIDINT	REAL(8)	INTEGER(2)
IDINT [6, 8]	REAL(8)	INTEGER(4)
KIDINT	REAL(8)	INTEGER(8)
IIQINT	REAL(16)	INTEGER(2)
IQINT[6, 9]	REAL(16)	INTEGER(4)
KIQINT	REAL(16)	INTEGER(8)
	COMPLEX(4), COMPLEX(8), COMPLEX(16)	INTEGER(2)
	COMPLEX(4), COMPLEX(8), COMPLEX(16)	INTEGER(4)

	INTEGER(8), REAL(4), REAL(8), REAL(16),	
	COMPLEX(4), COMPLEX(8), COMPLEX(16)	
INT4[10]	INTEGER(1), INTEGER(2), INTEGER(4),	INTEGER(4)
	INTEGER(8), REAL(4), REAL(8), REAL(16),	

Specific Name [1]	Argument Type	Result Type
	COMPLEX(4), COMPLEX(8), COMPLEX(16)	
INT8[10]	INTEGER(1), INTEGER(2), INTEGER(4), INTEGER(8), REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), COMPLEX(16)	INTEGER(8)

[1]These specific functions cannot be passed as actual arguments.

[2]This function can also be specified as HFIX.

[3]The setting of compiler options specifying integer size or real size can affect IFIX.

[4]For compatibility with older versions of Fortran, IFIX is treated as a generic function.

[5]Or JINT.

[6]The setting of compiler options specifying integer size can affect INT, IDINT, and IQINT.

[7]Or JIFIX.

[8]Or JIDINT. For compatibility with older versions of Fortran, IDINT can also be specified as a generic function.

[9]Or JIQINT. For compatibility with older versions of Fortran, IQINT can also be specified as a generic function.

[10]For compatibility, these functions can also be specified as generic functions.

If the argument is a binary, octal, or hexadecimal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

Example

INT (-4.2) has the value -4.

INT (7.8) has the value 7.

INTC

Portability Function: *Converts an INTEGER(4) argument to INTEGER(2) type.*

Module

USE IFPORT

Syntax

```
result = INTC (i)
```

i (Input) INTEGER(4). A value or expression.

Results

The result type is INTEGER(2). The result is the value of *i* with type INTEGER(2). Overflow is ignored.

INT_PTR_KIND

Inquiry Intrinsic Function (Specific): *Returns the INTEGER KIND that will hold an address. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.*

Syntax

```
result = INT_PTR_KIND( )
```

Results

The result type is default integer. The result is a scalar with the value equal to the value of the kind parameter of the integer data type that can represent an address on the targeted platform.

The result value is 4 on IA-32 target architecture; 8 on Intel® 64 architecture.

Example

```
REAL A(100)
POINTER (P, A)
INTEGER (KIND=INT_PTR_KIND()) SAVE_P
P = MALLOC (400)
SAVE_P = P
```

INTEGER Statement

Statement: *Specifies the INTEGER data type.*

Syntax

```
INTEGER
INTEGER([KIND=] n)
INTEGER*n
```

n Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind which holds the constant.

The default kind can also be changed by using the INTEGER directive or compiler options specifying integer size.

Example

```
! Entity-oriented declarations:
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER (2) :: k=4
INTEGER (2), PARAMETER :: limit=12

! Attribute-oriented declarations:
INTEGER days, hours
INTEGER (2):: k=4, limit
DIMENSION days(:), hours(:)
POINTER days, hours
PARAMETER (limit=12)
```

See Also

INTEGER Directive
Integer Data Types
Integer Constants

INTEGER Directive

General Compiler Directive: *Specifies the default integer kind.*

Syntax

```
!DIR$ INTEGER:{ 2 | 4 | 8 }
```

The INTEGER directive specifies a size of 2 (KIND=2), 4 (KIND=4), or 8 (KIND=8) bytes for default integer numbers.

When the INTEGER directive is in effect, all default integer variables are of the kind specified. Only numbers specified or implied as INTEGER without KIND are affected.

The INTEGER directive can only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module or a block data program unit. INTEGER cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

The default logical kind is the same as the default integer kind. So, when you change the default integer kind you also change the default logical kind.

Example

```
INTEGER i            ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)   ! still a 4-byte integer
                     !   not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
  !DIR$ INTEGER:2
  INTEGER j          ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```

INTENT

Statement and Attribute: *Specifies the intended use of one or more dummy arguments.*

Syntax

The INTENT attribute can be specified in a type declaration statement or an INTENT statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] INTENT (*intent-spec*) [, *att-ls*] :: *d-arg*[, *d-arg*]...

Statement:

INTENT (*intent-spec*) [::] *d-arg*[, *d-arg*] ...

type — Is a data type specifier.

att-ls — Is an optional list of attribute specifiers.

intent-spec — Is one of the following specifiers:

IN	Specifies that the dummy argument will be used only to provide data to the procedure. The dummy argument must not be redefined (or become undefined) during execution of the procedure.
OUT	Specifies that the dummy argument will be used to pass data from the procedure back to the calling program. The dummy argument is undefined on entry, although it may have subcomponents that are initialized by default. An undefined argument must be defined before it is referenced in the procedure. Any associated actual argument must be definable.
INOUT	Specifies that the dummy argument can both provide data to the procedure and return data to the calling program. Any associated actual argument must be definable.

d-arg — Is the name of a dummy argument or dummy pointer. It cannot be a dummy procedure.

Description

The INTENT statement can only appear in the specification part of a subprogram or interface body.

If no INTENT attribute is specified for a dummy argument, its use is subject to the limitations of the associated actual argument.

If a function specifies a defined operator, the dummy arguments must have intent IN.

If a subroutine specifies defined assignment, the first argument must have intent OUT or INOUT, and the second argument must have intent IN or the VALUE attribute, or both IN and the VALUE attribute.

An entity with the INTENT (OUT) attribute must not be an allocatable coarray or have a subobject that is an allocatable coarray. It must not be of, or have a subcomponent of, type EVENT_TYPE or type LOCK_TYPE from the ISO_FORTRAN_ENV module.

A non-pointer dummy argument with intent IN (or a subobject of such a dummy argument) must *not* appear as any of the following:

- A DO variable
- The variable of an assignment statement
- The *pointer-object* of a pointer assignment statement
- An *object* or STAT variable in an ALLOCATE or DEALLOCATE statement
- An input item in a READ statement
- A variable name in a NAMELIST statement if the namelist group name appears in a NML specifier in a READ statement
- An internal file unit in a WRITE statement
- A definable variable in an INQUIRE statement
- An IOSTAT or SIZE specifier in an I/O statement
- An actual argument in a reference to a procedure with an explicit interface if the associated dummy argument has intent OUT or INOUT

INTENT on a pointer dummy argument refers to the pointer association status of the pointer and has no effect on the value of the target of the pointer.

A pointer dummy argument with intent IN (or a subobject of such a pointer argument) must *not* appear as any of the following:

- A *pointer-object* in a NULLIFY statement
- A *pointer-object* in a pointer assignment statement
- An *object* in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

A pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute. During the execution of the procedure, it is pointer associated with the actual argument.

If an actual argument is an array section with a vector subscript, it cannot be associated with a dummy array that is defined or redefined (has intent OUT or INOUT).

On entry to a routine, given an INTENT(OUT) dummy argument:

- If it is a pointer, it should be deallocated.
- If it is an allocatable, all of its allocatable subcomponents should be deallocated, and then it should also be deallocated.
- If it is a non-pointer, non-allocatable, all its allocatable subcomponents should be deallocated, and then default initialization should be applied, as specified by the program.

Example

The following example shows type declaration statements specifying the INTENT attribute:

```
SUBROUTINE TEST(I, J)
  INTEGER, INTENT(IN) :: I
  INTEGER, INTENT(OUT), DIMENSION(I) :: J
```

The following are examples of the INTENT statement:

```
SUBROUTINE TEST(A, B, X)
   INTENT(INOUT) :: A, B
   ...
SUBROUTINE CHANGE(FROM, TO)
   USE EMPLOYEE_MODULE
   TYPE(EMPLOYEE) FROM, TO
   INTENT(IN) FROM
   INTENT(OUT) TO
   ...
```

The following shows another example:

```
SUBROUTINE AVERAGE(value,data1, cube_ave)
  TYPE DATA
          INTEGER count
          REAL avg
        END TYPE
        TYPE(DATA) data1
        REAL tmp
  ! value cannot be changed, while cube_ave must be defined
  ! before it can be used. Data1 is defined when the procedure is
  ! invoked, and becomes redefined in the subroutine.
  INTENT(IN)::value; INTENT(OUT)::cube_ave
  INTENT(INOUT)::data1
  ! count number of times AVERAGE has been called on the data set
  ! being passed.
  tmp = data1%count*data1%avg + value
  data1%count = data1%count + 1
  data1%avg = tmp/data1%count
  cube_ave = data1%avg**3
END SUBROUTINE
```

ISO_FORTRAN_ENV
Compatible attributes

INTERFACE

Statement: *Defines an explicit interface for an external or dummy procedure. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.*

Syntax

```
INTERFACE [generic-spec]
   [interface-body]...
   [[MODULE]PROCEDURE [::]name-list]...
END INTERFACE [generic-spec]
```

generic-spec (Optional) Is one of the following:

- A generic name

For information on generic names, see Defining Generic Names for Procedures.

- OPERATOR (*op*)

  Defines a generic operator (*op*). It can be a defined unary, defined binary, or extended intrinsic operator. For information on defined operators, see Defining Generic Operators.
- ASSIGNMENT (=)

  Defines generic assignment. For information on defined assignment, see Defining Generic Assignment.

interface-body

Is one or more function or subroutine subprograms or a procedure pointer.

An interface body must *not* contain a DATA, ENTRY, statement function, or FORMAT statement. An entry name can be used as a procedure name.

The subprogram can contain a USE statement. It can also contain the prefix MODULE before FUNCTION or SUBROUTINE to indicate a separate module procedure.

The subprogram can contain an IMPORT statement to make entities from the interfaces host scoping unit accessible to the interface body.

Executable code and specification statements that are not used to specify characteristics of the subprogram or its dummy arguments in an interface body are ignored.

name-list

Is the name of one or more nonintrinsic procedures that are accessible in the host. The MODULE keyword is only allowed if the interface block specifies a *generic-spec* and has a host that is a module, or accesses a module by use association.

The characteristics of module procedures or internal procedures are not given in interface blocks, but are assumed from the module subprogram definitions or the USE associated interfaces.

Description

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

A *generic-spec* can only appear in the END INTERFACE statement if one appears in the INTERFACE statement; they must be identical.

The characteristics specified for the external or dummy procedure must be consistent with those specified in the procedure's definition.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association unless an IMPORT statement appears in an interface body.

Internal, module, and intrinsic procedures are all considered to have explicit interfaces. External procedures have implicit interfaces by default; when you specify an interface block for them, their interface becomes explicit. A procedure must not have more than one explicit interface in a given scoping unit. This means that you cannot include internal, module, or intrinsic procedures in an interface block, unless you want to define a generic name for them.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

A interface block containing *generic-spec* specifies a generic interface for the following procedures:

- The procedures within the interface block

  Any generic name, defined operator, or equals symbol that appears is a generic identifier for all the procedures in the interface block. For the rules on how any two procedures with the same generic identifier must differ, see Unambiguous Generic Procedure References.
- The module procedures listed in the MODULE PROCEDURE statement

  The module procedures must be accessible by a USE statement.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

The following rules apply to interface blocks containing pure procedures:

- The interface specification of a pure procedure must declare the INTENT of all dummy arguments except pointer and procedure arguments.
- A procedure that is declared pure in its definition can also be declared pure in an interface block. However, if it is not declared pure in its definition, it must not be declared pure in an interface block.

Example

The following example shows a simple procedure interface block with no generic specification:

```
SUBROUTINE SUB_B (B, FB)
  REAL B
  ...
  INTERFACE
    FUNCTION FB (GN)
      REAL FB, GN
    END FUNCTION
  END INTERFACE
```

The following shows another example:

```
!An interface to an external subroutine SUB1 with header:
!SUBROUTINE SUB1(I1,I2,R1,R2)
!INTEGER I1,I2
!REAL R1,R2
INTERFACE
  SUBROUTINE SUB1(int1,int2,real1,real2)
    INTEGER int1,int2
    REAL real1,real2
  END SUBROUTINE SUB1
END INTERFACE
INTEGER int
...
```

Use and Host Association

INTERFACE TO

Statement: *Identifies a subprogram and its actual arguments before it is referenced or called.*

Syntax

```
INTERFACE TO subprogram-stmt
   [formal-declarations]
END
```

subprogram-stmt	Is a function or subroutine declaration statement.
formal-declarations	(Optional) Are type declaration statements (including optional attributes) for the arguments.

The INTERFACE TO block defines an explicit interface, but it contains specifications for only the procedure declared in the INTERFACE TO statement. The explicit interface is defined only in the program unit that contains the INTERFACE TO statement.

The recommended method for defining explicit interfaces is to use an INTERFACE block.

Example

Consider that a C function that has the following prototype:

```
extern void Foo (int i);
```

The following INTERFACE TO block declares the Fortran call to this function:

```
INTERFACE TO SUBROUTINE Foo [C.ALIAS: '_Foo'] (I)
  INTEGER*4 I
END

INTERFACE

INTEROP

OpenMP* Fortran Compiler Directive: *Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.*

Syntax

```
!$OMP INTEROP clause[[[,] clause]... ]
```

clause	Is one or more of the following: • DEPEND ([depend-modifier,] dependence-type : locator-list) A DEPEND clause can appear only if TARGETSYNC appears as the *interop-type* in an *action-clause*, or if *interop-var* is initialized with the TARGETSYNC *interop-type*.

- DEVICE (scalar-integer-expression)

  Only one DEVICE clause can appear in the directive. The *integer-expression* of the DEVICE clause must evaluate to a non-negative value equal to or less than the result of a call to the omp_get_num_devices runtime function.
- NOWAIT

  Only one NOWAIT clause is permitted in the directive.
- An *action-clause*

action-clause

Is one of the following:

- `INIT` (*modifier-list* : *interop-var*)

  Causes the *interop-var* to be initialized to refer to the list of properties associated with the specified *interop-type*.

  The properties `device_num`, `type`, `type_name`, `vendor`, and `vendor_name` are available for all *interop-type*s.

  If the specified device does not exist or it is not supported, the *interop-var* is initialized to the value of omp_interop_none, which is defined to be zero.
- `DESTROY` (*interop-var*)

  Causes *interop-var* to be set to omp_interop_none after the resources associated with the *interop-var* are released. This action makes *interop-var* unusable until it is reinitialized by another INTEROP construct.
- `USE` (*interop-var*)

  Causes *interop-var* to be used for the effects of the directive, but *interop-var* is not initialized, destroyed, or modified.

You must specify at least one *action-clause*. Each *interop-type* can appear at most once in an *action-clause*.

For the USE and DESTROY *action-clause*s, the *interop-type* is whatever *interop-type* was used when initializing the *interop-var*.

modifier-list

Is *interop-type* [[, *interop-type*] . . .]

interop-type

Is one of the following:

- PREFER_TYPE (*preference-list*)
- TARGET

  Provides the following properties:

  - device - the foreign device handle
  - device_context - the foreign device context handle
  - platform - the handle to the foreign platform of the device
- TARGETSYNC

  Enables synchronization between foreign tasks executing in the foreign execution context and OpenMP* tasks.

TARGET and TARGETSYNC may appear at most once in the clause. At least one modifier must be specified.

preference-list	Is a list of one or more *foreign-runtime-id*s, which can be character constants or integer constant expressions with kind type omp_interop_fr_kind. If you specify more than one *foreign-runtime-id*, they must be separated by commas. The character values recognized by ifx are "opencl", "sycl", and "level_zero", which have corresponding integer values of 3, 4, and 6, respectively. You can specify integer constants OMP_IFR_OPENCL, OMP_IFR_SYCL, and OMP_IFR_LEVEL_ZERO in the *preference-list*. Definitions for these integer constants are in module omp_lib. Other character, integer, or named constants are accepted and silently ignored. The list of *foreign-runtime-id*s is scanned in left-to-right lexical order. The left-most supported *foreign-runtime-id* in *preference-list* is used. If the implementation does not support any of the listed *foreign-runtime-id*s in *preference-list*, the behavior is unspecified.
interop-var	Is a scalar integer variable with kind type omp_interop_kind. The *interop-var* of an INIT or DESTROY *action-clause* must not be a constant. The same *interop-var* cannot be specified in more than one *action-clause* of the INTEROP construct.

A task that encounters an INTEROP construct executes the region.

If a DEVICE clause is not specified, the behavior is as if a DEVICE clause is present with the integer value equal to the value of the internal control variable (ICV) `default-device-var` specified.

OpenMP* may interoperate with one or more foreign runtime environments using the INTEROP directive, the INTEROP clause on a DECLARE VARIANT directive, or the interoperability functions in the OpenMP* runtime API.

A task has an interoperability requirement set, which is a logical set of properties. Properties can be added to or removed from the set by different directives. The properties can be queried by other constructs that have interoperability semantics. The following properties can be added by a construct:

- DEPEND - requires the construct enforce the synchronization relationship specified by the DEPEND clause
- IS_DEVICE_PTR (*list-item*) - indicates that the *list-item* is a device pointer within the construct
- NOWAIT - indicates that the construct is asynchronous

The DISPATCH directive can add properties to the interoperability requirement set.

The DECLARE VARIANT directive can remove properties from the interoperability requirement set.

If the *interop-var* is initialized with TARGETSYNC, an empty mergeable task is generated. DEPEND clauses apply to the generated task. If NOWAIT is omitted, the generated task is also an included task. The INTEROP construct guarantees ordered execution of the generated task with respect to foreign tasks executing in foreign contexts through the foreign synchronization object accessible through the TARGETSYNC property of the *interop-var*.

If a foreign task is created prior to encountering an INTEROP construct, the foreign task must complete execution before the generated task executes. If the creation of a foreign task occurs after an INTEROP construct is encountered, the foreign task cannot begin execution until the generated task finishes execution. The INTEROP construct imposes no ordering between the thread that encounters it and foreign tasks or OpenMP* tasks.

INTRINSIC

Statement and Attribute: *Allows the specific name of an intrinsic procedure to be used as an actual argument.*

Syntax

The INTRINSIC attribute can be specified in a type declaration statement or an INTRINSIC statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] INTRINSIC [, *att-ls*] :: *in-pro*[, *in-pro*]...

Statement:

INTRINSIC [::] *in-pro*[, *in-pro*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
in-pro	Is the name of an intrinsic procedure.

Description

In a type declaration statement, only *functions* can be declared INTRINSIC. However, you can use the INTRINSIC *statement* to declare subroutines, as well as functions, to be intrinsic.

The name declared INTRINSIC is assumed to be the name of an intrinsic procedure. If a generic intrinsic function name is given the INTRINSIC attribute, the name retains its generic properties.

Some specific intrinsic function names cannot be used as actual arguments. For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures.

Example

The following example shows a type declaration statement specifying the INTRINSIC attribute:

```
PROGRAM EXAMPLE
...
REAL(8), INTRINSIC :: DACOS
...
CALL TEST(X, DACOS)     ! Intrinsic function DACOS is an actual argument
```

The following example shows an INTRINSIC statement:

Main Program	Subprogram
EXTERNAL CTN	SUBROUTINE TRIG(X,F,Y)
INTRINSIC SIN, COS	Y = F(X)
. . .	RETURN
	END
CALL TRIG(ANGLE,SIN,SINE)	
. . .	FUNCTION CTN(X)

Main Program	Subprogram
	CTN = COS(X)/SIN(X)
CALL TRIG(ANGLE,COS,COSINE)	RETURN
...	END
CALL TRIG(ANGLE,CTN,COTANGENT)	

Note that when TRIG is called with a second argument of SIN or COS, the function reference F(X) references the Standard Fortran library functions SIN and COS; but when TRIG is called with a second argument of CTN, F(X) references the user function CTN.

The following shows another example:

```
    INTRINSIC SIN, COS
    REAL X, Y, R
!   SIN and COS are arguments to Calc2:
    R = Calc2 (SIN, COS)
```

INUM

Elemental Intrinsic Function (Specific): *Converts a character string to an INTEGER(2) value. This function cannot be passed as an actual argument.*

Syntax

`result = INUM (i)`

i (Input) Must be of type character.

Results

The result type is INTEGER(2). The result value is the INTEGER(2) value represented by the character string *i*.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example

INUM ("451") has the value 451 of type INTEGER(2).

IOR

Elemental Intrinsic Function (Generic): *Performs an inclusive OR on corresponding bits. This function can also be specified as OR.*

Syntax

`result = IOR (i,j)`

i (Input) Must be of type integer, logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer, they must have the same kind type parameter. If the kinds of *i* and *j* do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. *i* and *j* must not both be binary, octal, or hexadecimal literal constants.

Results

The result is the same as *i* if *i* is of type integer; otherwise, the result is the same as *j*. If either *i* or *j* is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining *i* and *j* bit-by-bit according to the following truth table:

```
  i   j   IOR (i, j)
  1   1       1
  1   0       1
  0   1       1
  0   0       0
```

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BIOR	INTEGER(1)	INTEGER(1)
IIOR[1]	INTEGER(2)	INTEGER(2)
JIOR	INTEGER(4)	INTEGER(4)
KIOR	INTEGER(8)	INTEGER(8)

[1]Or HIOR.

Example

IOR (1, 4) has the value 5.

IOR (1, 2) has the value 3.

The following shows another example:

```
INTEGER result
result = IOR(240, 90) ! returns 250
```

IANY
IPARITY

IPARITY

Transformational Intrinsic Function (Generic):
Returns the result of a bitwise exclusive OR operation.

Syntax

```
result = IPARITY (array, dim [, mask])
result = IPARITY (array [, mask])
```

array	(Input) Must be an array of type integer.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.

Results

The result has the same type and kind parameters as *array*. It is scalar if *dim* does not appear; otherwise, the result has rank *n* - 1 and shape [d_1, d_2, ..., d_{dim-1}, d_{dim+1} , ..., d_n] where [d_1, d_2,..., d_n] is the shape of *array*.

The result of IPARITY (*array*) has a value equal to the bitwise exclusive OR of all the elements of *array*. If *array* has size zero, the result value is equal to zero.

The result of IPARITY (*array*, MASK=*mask*) has a value equal to IPARITY (PACK (*array*, *mask*)).

The result of IPARITY (*array*, DIM=*dim* [, MASK=*mask*]) has a value equal to that of IPARITY (*array* [, MASK=*mask*]) if *array* has rank one. Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1} , ..., s_n) of the result is equal to IPARITY (*array* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n) [, MASK = *mask* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n)]).

Example

IPARITY ([14, 13, 8]) has the value 11. IPARITY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 6.

IRAND, IRANDM

Portability Functions: *Return random numbers in the range 0 through (2**31)-1, or 0 through (2**15)-1 if called without an argument.*

Module

USE IFPORT

Syntax

```
result = IRAND ([iflag])
result = IRANDM ([iflag])
```

iflag	(Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If *iflag* is omitted, it is assumed to be 0, and the return range is 0 through (2**15)-1 (inclusive).

Results

The result type is INTEGER(4). If *iflag* is 1, the generator is restarted and the first random value is returned. If *iflag* is 0, the next random number in the sequence is returned. If *iflag* is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

Example

```
USE IFPORT
INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND (flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do
```

IRANGET

IS_CONTIGUOUS

Inquiry Intrinsic Function (Generic): *Tests the contiguity of an array.*

Syntax

```
result = IS_CONTIGUOUS (array)
```

array	(Input) Is an array; it can be of any data type. If it is a pointer, it must be associated.

Results

The result is default logical scalar. The result has the value .TRUE. if array is contiguous; otherwise, .FALSE..

Example

After the pointer assignment MY_P => TARGET (2:20:4), IS_CONTIGUOUS (MY_P) has the value .FALSE..

See Also

CONTIGUOUS

IS_DEVICE_PTR Clause

Parallel Directive Clause: *Indicates that a list item is a device pointer currently in the device data environment and that it should be used directly.*

Syntax

```
IS_DEVICE_PTR (list)
```

list	Is a list of one or more variables that are of type C_PTR from the intrinsic module ISO_C_BINDING, or that do not have the POINTER, ALLOCATABLE, or VALUE attribute[1]. Each *list* item is a device pointer currently in the device data environment and that it should be used directly.

[1] List items not of type C_PTR have been deprecated in the OpenMP* specification.

If a *list* item in a MAP clause is an array section, and the array section is derived from a variable with a POINTER or ALLOCATABLE attribute, then the behavior is unspecified if the corresponding list item's variable is modified in the region.

A *list* item may be a device address returned as the result of a call to the OpenMP* runtime library memory management function `omp_target_alloc` function.

IS_IOSTAT_END

Elemental Intrinsic Function (Generic): *Tests for an end-of-file condition.*

Syntax

```
result=IS_IOSTAT_END(i)
```

i	(Input) Must be of type integer.

Results

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-file condition.

Example

```
INTEGER IO_STATUS
…
READ (20, IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_END (IO_STATUS)) THEN
…                                ! process end of file
ENDIF
…                                ! process data read
```

IS_IOSTAT_EOR

Elemental Intrinsic Function (Generic): *Tests for an end-of-record condition.*

Syntax

`result=IS_IOSTAT_EOR(i)`

i	(Input) Must be of type integer.

Results

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-record condition.

Example

```
INTEGER IO_STATUS
…
READ (30, ADVANCE='YES', IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_EOR (IO_STATUS)) THEN
…                                ! process end of record
ENDIF
…                                ! process data read
```

ISATTY

Portability Function: *Checks whether a logical unit number is a terminal.*

Module

USE IFPORT

Syntax

`result = ISATTY (lunit)`

iunit	(Input) INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.

Results

The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..

If *lunit* is out of range or is not connected, zero is returned.

ISHA

Elemental Intrinsic Function (Generic): *Arithmetically shifts an integer left or right by a specified number of bits.*

Syntax

```
result = ISHA (i,shift)
```

i	(Input) Must be of type integer. This argument is the value to be shifted.
shift	(Input) Must be of type integer. This argument is the direction and distance of shift. Positive shifts are left (toward the most significant bit); negative shifts are right (toward the least significant bit).

Results

The result type and kind are the same as *i*. The result is equal to *i* shifted arithmetically by *shift* bits.

If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. If the shift is to the left, zeros are shifted in on the right. If the shift is to the right, copies of the sign bit (0 for non-negative *i*; 1 for negative *i*) are shifted in on the left.

The kind of integer is important in arithmetic shifting because sign varies among integer representations (see the following example). If you want to shift a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

Example

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = -128             ! equal to 10000000
j = -32768           ! equal to 10000000 00000000
res1 = ISHA (i, -4)  ! returns 11111000 = -8
res2 = ISHA (j, -4)  ! returns 11111000 10100000 = -2048
```

ISHC
ISHL
ISHFT
ISHFTC

ISHC

Elemental Intrinsic Function (Generic): *Rotates an integer left or right by specified number of bits. Bits shifted out one end are shifted in the other end. No bits are lost.*

Syntax

```
result = ISHC (i,shift)
```

i	(Input) Must be of type integer. This argument is the value to be rotated.
shift	(Input) Must be of type integer. This argument is the direction and distance of rotation. Positive rotations are left (toward the most significant bit); negative rotations are right (toward the least significant bit).

Results

The result type and kind are the same as *i*. The result is equal to *i* circularly rotated by *shift* bits.

If *shift* is positive, *i* is rotated left *shift* bits. If *shift* is negative, *i* is rotated right *shift* bits. Bits shifted out one end are shifted in the other. No bits are lost.

The kind of integer is important in circular shifting. With an INTEGER(4) argument, all 32 bits are shifted. If you want to rotate a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

Example

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHC (i, -3)   ! returns 01000001 = 65
res2 = ISHC (j, -3)   ! returns 01000000 00000001 =
                      ! 16385
```

See Also

ISHA
ISHL
ISHFT
ISHFTC

ISHFT

Elemental Intrinsic Function (Generic): *Performs a logical shift.*

Syntax

`result = ISHFT (i,shift)`

i	(Input) Must be of type integer.
shift	(Input) Must be of type integer. The absolute value for *shift* must be less than or equal to BIT_SIZE(*i*).

Results

The result type and kind are the same as *i*. The result has the value obtained by shifting the bits of *i* by *shift* positions. If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. Zeros are shifted in from the opposite end.

ISHFT with a positive *shift* can also be specified as LSHIFT (or LSHFT). ISHFT with a negative *shift* can also be specified as RSHIFT (or RSHFT) with | *shift* |.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BSHFT	INTEGER(1)	INTEGER(1)
IISHFT[1]	INTEGER(2)	INTEGER(2)
JISHFT	INTEGER(4)	INTEGER(4)
KISHFT	INTEGER(8)	INTEGER(8)

[1]Or HSHFT.

Example

ISHFT (2, 1) has the value 4.

ISHFT (2, -1) has the value 1.

The following shows another example:

```
INTEGER(1) i, res1
INTEGER(2) j, k(3), res2
i = 10 ! equal to 00001010
j = 10 ! equal to 00000000 00001010
res1 = ISHFT (i, 5)  ! returns 01000000 = 64
res2 = ISHFT (j, 5)  ! returns 00000001 01000000 =
                     ! 320
k = ISHFT((/3, 5, 1/), (/1, -1, 0/))  ! returns array
                                      ! /6, 2, 1/
```

BIT_SIZE
ISHFTC
ISHA
ISHC

ISHFTC

Elemental Intrinsic Function (Generic): *Performs a circular shift of the rightmost bits.*

Syntax

`result = ISHFTC (i,shift[,size])`

i	(Input) Must be of type integer.
shift	(Input) Must be of type integer. The absolute value of *shift* must be less than or equal to *size*. [1]
size	(Input; optional) Must be of type integer. The value of *size* must be positive[2] and must not exceed BIT_SIZE(*i*). If *size* is omitted, it is assumed to have the value of BIT_SIZE(*i*).

[1]SHIFT can be a value whose absolute value is greater than SIZE. In this case, the effect is as if SHIFT has the value MOD (SHIFT, SIZE) if SIZE is positive.

[2]SIZE can be zero. In this case, no circular shift is performed and the function result is the value of *i*, the first argument.

Results

The result type and kind are the same as *i*. The result value is obtained by circular shifting the *size* rightmost bits of *i* by *shift* positions. If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.

No bits are lost. Bits in *i* beyond the value specified by *size* are unaffected.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BSHFTC	INTEGER(1)	INTEGER(1)
IISHFTC[3]	INTEGER(2)	INTEGER(2)
JISHFTC	INTEGER(4)	INTEGER(4)
KISHFTC	INTEGER(8)	INTEGER(8)

[3]Or HSHFTC.

Example

ISHFTC (4, 2, 4) has the value 1.

ISHFTC (3, 1, 3) has the value 6.

The following shows another example:

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHFTC (i, 2, 3)   ! rotates the 3 rightmost
                          ! bits by 2 (left) and
                          ! returns 00001001 = 9
res1 = ISHFTC (i, -2, 3)  ! rotates the 3 rightmost
                          ! bits by -2 (right) and
                          ! returns 00001100 = 12
res2 = ISHFTC (j, 2, 3)   ! rotates the 3 rightmost
                          ! bits by 2 and returns
                          ! 00000000 00001001 = 9
```

BIT_SIZE
ISHFT
MVBITS

ISHL

Elemental Intrinsic Function (Generic): *Logically shifts an integer left or right by the specified bits. Zeros are shifted in from the opposite end.*

Syntax

```
result = ISHL (i,shift)
```

i	(Input) Must be of type integer. This argument is the value to be shifted.
shift	(Input) Must be of type integer. This argument is the direction and distance of shift. If positive, *i* is shifted left (toward the most significant bit). If negative, *i* is shifted right (toward the least significant bit).

Results

The result type and kind are the same as *i*. The result is equal to *i* logically shifted by *shift* bits. Zeros are shifted in from the opposite end.

Unlike circular or arithmetic shifts, which can shift ones into the number being shifted, logical shifts shift in zeros only, regardless of the direction or size of the shift. The integer kind, however, still determines the end that bits are shifted out of, which can make a difference in the result (see the following example).

Example

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10   ! equal to 00001010
j = 10   ! equal to 00000000 00001010
res1 = ISHL (i, 5)   ! returns 01000000 = 64
res2 = ISHL (j, 5)   ! returns 00000001 01000000 = 320
```

ISNAN

Elemental Intrinsic Function (Generic): *Tests whether IEEE* real (binary32, binary64, and binary128) numbers are Not-a-Number (NaN) values.*

Syntax

```
result = ISNAN (x)
```

x	(Input) Must be of type real.

Results

The result type is default logical. The result is .TRUE. if *x* is an IEEE NaN; otherwise, the result is .FALSE..

Example

```
LOGICAL A
DOUBLE PRECISION B
...
A = ISNAN(B)
```

A is assigned the value .TRUE. if B is an IEEE NaN; otherwise, the value assigned is .FALSE..

ITERATOR Clause Modifier

Parallel Directive Clause Modifier: *An identifier that assumes multiple values in the clause in which it appears. This feature is only available for ifx.*

Syntax

`ITERATOR (`*`iterators-definition`*`)`

`iterators-definition`	Is *iterators-specifier* [, *iterators-definition*]
`iterators-specifier`	Is [*iterator-type* ::] *iterator* = *range-spec*
`iterator-type`	Is an integer type. If not specified, the iterator type is default integer.
`iterator`	Is a Fortran identifier.
`range-spec`	Has the form: *first* : *last* [: *stride*] where *first* and *last* are scalar expressions that can be converted to *iterator-type*, and *stride* is a scalar, non-zero integer expression. If *stride* is not specified, it is assumed to be 1.

Description

An iterator is similar in function to an implied DO variable. If a list-item in a clause is modified with an iterator, it is as if the list-item appears in the clause with each value of the iterator that the iterator assumes in the clause. If the set of values the iterator assumes is empty, it is as if the list item did not appear in the clause.

An iterator assumes the values $i_1 \ldots i_N$ where i_1 = first, $i_j = i_{j-1}$ + stride where j >= 2 and

if stride > 0:	i_1 <= last
	i_N <= last
	i_N + stride > last
if stride < 0:	i_1 >= last
	i_N >= last
	i_N + stride < last

For each value *i* in the set of values the *iterator* assumes, the value *i* + *stride* must be representable as a value of type *iterator-type*.

The scope of an *iterator* is the clause argument (list-item) that it modifies. It blocks accessible symbols with the same name in the context of the clause item it modifies. A variable used in an expression of a *range-spec* is an implicit reference to that variable in all enclosing OpenMP constructs.

An *iterator* cannot appear in a *range-spec* in the same clause. An *iterator* can only be defined once in a clause.

If the value of *stride* is zero, the behavior is undefined.

Example

In the following example, the parallel region uses a SINGLE construct containing a loop to generate n tasks, each with an OUT dependency specified through an element of the array vector. Each task calls subroutine `ASSIGN_ELEMENT` to assign the value `i` to the corresponding element of the array vector.

Following the loop, another task is generated with `n` IN dependencies, one for each element of the array vector. The dependencies are created using an iterator. This task waits for the tasks generated by the loop to complete and then calls `PRINT_VECTOR` to print the elements of the array vector.

```
SUBROUTINE SUB (VECTOR, N)
INTEGER  :: I, N, VECTOR (N)
  !$OMP PARALLEL
   !$OMP SINGLE
     DO I=1,N
       !$OMP TASK DEPEND (OUT: VECTOR (I))
          CALL ASSIGN_ELEMENT (VECTOR(I), I)
       !$OMP END TASK
     END DO

     !$OMP TASK DEPEND (ITERATOR (INTEGER :: ITER = 1:N), IN: VECTOR(ITER))
        CALL PRINT_VECTOR (VECTOR, N)
     !$OMP END TASK
    !$OMP END SINGLE
   !$OMP END PARALLEL
END SUBROUTINE SUB
```

ITIME

Portability Subroutine: *Returns the time in numeric form.*

Module

USE IFPORT

Syntax

`CALL ITIME (array)`

array	(Output) INTEGER(4). A rank one array with three elements used to store numeric time data: • *array*(1) - the hour • *array*(2) - the minute • *array*(3) - the second

Example

```
USE IFPORT
 INTEGER(4) time_array(3)
 CALL ITIME (time_array)
 write(*,10) time_array
 10 format (1X,I2,':',I2,':',I2)
 END
```

DATE_AND_TIME

IVDEP

General Compiler Directive: *Assists the compiler's dependence analysis of iterative DO loops.*

Syntax

`!DIR$ IVDEP [: option]`

option	Is LOOP or BACK.

The IVDEP directive is an assertion to the compiler's optimizer about the order of memory references inside a DO loop.

IVDEP:LOOP implies no loop-carried dependencies. IVDEP:BACK implies no backward dependencies.

When no *option* is specified, the following occurs:

- The compiler begins dependence analysis by assuming all dependences occur in the same forward direction as their appearance in the normal scalar execution order. This contrasts with normal compiler behavior, which is for the dependence analysis to make no initial assumptions about the direction of a dependence.

!DIR$ IVDEP with no option can also be spelled !DIR$ INIT_DEP_FWD (INITialize DEPendences ForWarD).

The IVDEP directive is applied to a DO loop in which the user knows that dependences are in lexical order. For example, if two memory references in the loop touch the same memory location and one of them modifies the memory location, then the first reference to touch the location has to be the one that appears earlier lexically in the program source code. This assumes that the right-hand side of an assignment statement is "earlier" than the left-hand side.

The IVDEP directive informs the compiler that the program would behave correctly if the statements were executed in certain orders other than the sequential execution order, such as executing the first statement or block to completion for all iterations, then the next statement or block for all iterations, and so forth. The optimizer can use this information, along with whatever else it can prove about the dependences, to choose other execution orders.

Example

In the following example, the IVDEP directive provides more information about the dependences within the loop, which may enable loop transformations to occur:

```
!DIR$ IVDEP
      DO I=1, N
         A(INDARR(I)) = A(INDARR(I)) + B(I)
      END DO
```

In this case, the scalar execution order follows:

1. Retrieve INDARR(I).
2. Use the result from step 1 to retrieve A(INDARR(I)).
3. Retrieve B(I).
4. Add the results from steps 2 and 3.
5. Store the results from step 4 into the location indicated by A(INDARR(I)) from step 1.

IVDEP directs the compiler to initially assume that when steps 1 and 5 access a common memory location, step 1 always accesses the location first because step 1 occurs earlier in the execution sequence. This approach lets the compiler reorder instructions, as long as it chooses an instruction schedule that maintains the relative order of the array references.

J to L

This section describes language features that start with J, K, or L.

J to L

JABS

Portability Function: *Returns an absolute value.*

Module

USE IFPORT

Syntax

```
result = JABS (i)
```

i (Input) INTEGER(4). A value.

Results

The result type is INTEGER(4). The value of the result is | *i* |.

JDATE

Portability Function: *Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.*

Module

USE IFPORT

Syntax

```
result = JDATE( )
```

Results

The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.

The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.

> **Caution**
> The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example

```
! Sets julian to today's julian date
    USE IFPORT
    CHARACTER*8 julian
    julian = JDATE( )
```

See Also

DATE_AND_TIME

JDATE4

Portability Function: *Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.*

Module

USE IFPORT

Syntax

```
result = JDATE4( )
```

Results

The result type is character with length 10. The result is the Julian date, in the form YYYYDDD, followed by three spaces.

The Julian date is a seven-digit number whose first four digits are the year, and whose final three represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 1999032.

See Also

DATE_AND_TIME

JNUM

Elemental Intrinsic Function (Specific): *Converts a character string to an INTEGER(4) value. This function cannot be passed as an actual argument.*

Syntax

```
result = JNUM (i)
```

i	(Input) Must be of type character.

Results

The result type is INTEGER(4). The result value is the integer value represented by the character string *i*.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example

JNUM ("46616") has the value 46616 of type INTEGER(4).

KILL

Portability Function: *Sends a signal to the process given by ID.*

Module

USE IFPORT

Syntax

```
result = KILL (pid,signum)
```

pid	(Input) INTEGER(4). ID of a process to be signaled.
signum	(Input) INTEGER(4). A signal value. For the definition of signal values, see the SIGNALfunction.

Results

The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error code. Possible error codes are:

- EINVAL: The *signum* is not a valid signal number, or PID is not the same as getpid( ) and *signum* does not equal SIGKILL.
- ESRCH: The given PID could not be found.
- EPERM: The current process does not have permission to send a signal to the process given by PID.

On Windows* systems, arbitrary signals can be sent only to the calling process (where *pid*= getpid( )). Other processes can send only the SIGKILL signal (*signum*= 9), and only if the calling process has permission.

Example

```
USE IFPORT
integer(4) id_number, sig_val, istat
id_number=getpid( )
ISTAT = KILL (id_number, sig_val)
```

See Also

SIGNAL
RAISEQQ
SIGNALQQ

KIND

Inquiry Intrinsic Function (Generic): *Returns the kind parameter of the argument.*

Syntax

`result = KIND (x)`

x	(Input) Can be of any intrinsic type.

Results

The result is a scalar of type default integer. The result has a value equal to the kind type parameter value of *x*.

Example

KIND (0.0) has the kind value of default real type.

KIND (12) has the kind value of default integer type.

The following shows another example:

```
INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)  ! still a 4-byte integer
                    ! not affected by setting in subroutine
END
SUBROUTINE INTEGER2( )
  !DIR$INTEGER:2
  INTEGER j ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```

KNUM

Elemental Intrinsic Function (Specific): *Converts a character string to an INTEGER(8) value.*

Syntax

```
result = KNUM (i)
```

i	(Input) Must be of type character.

Results

The result type is INTEGER(8). The result value is the integer value represented by the character string *i*.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

Example

KNUM ("46616") has the value 46616 of type INTEGER(8).

LASTPRIVATE

Parallel Directive Clause: *Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.*

Syntax

```
LASTPRIVATE ([CONDITIONAL:] list)
```

CONDITIONAL	Is an optional modifier specifying that the last value assigned to a *list* item can be from the sequentially last iteration of the associated loops or the lexically last section construct.
list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /). If CONDITIONAL is present, *list* items must be scalar of intrinsic type (INTEGER, REAL, COMPLEX, LOGICAL, and CHARACTER) and they must have neither the POINTER nor the ALLOCATABLE attribute.

Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel region is exited, each variable has the value provided by the sequentially last section or loop iteration.

Multiple LASTPRIVATE clauses are allowed on all of the directives that accept them. A *list* item may not appear in more than one LASTPRIVATE clause. LASTPRIVATE (CONDITIONAL:A,B) is equivalent to LASTPRIVATE(CONDITIONAL:A) LASTPRIVATE(CONDITIONAL:B).

LASTPRIVATE (CONDITIONAL:list) can appear in the following directives:

- OMP DISTRIBUTE
- OMP DO
- OMP SECTIONS
- OMP SIMD
- OMP TASKLOOP
- Any and all of the combination directives of the above directives

The OMP PARALLEL directive does not allow the LASTPRIVATE clause.

If the original variable has the POINTER attribute, its update occurs as if by pointer assignment.

If the original variable does not have the POINTER attribute, its update occurs as if by intrinsic assignment.

When a LASTPRIVATE clause without the CONDITIONAL modifier appears in a worksharing or a SIMD directive, the value of each new *list* item from the sequentially last iteration of the associated loops, or the lexically last section, is assigned to the original *list* item.

When the CONDITIONAL modifier is specified, the final value written by the sequentially last iteration or lexically last section that writes to a *list* item, if any, is assigned to the original *list* item.

When the CONDITIONAL modifier is *not* specified, *list* items that are not assigned a value by the sequentially last iteration of the loops, or by the lexically last section, have unspecified values after the construct.

Therefore, variables specified in the *list* of a LASTPRIVATE clause that contains a CONDITIONAL modifier should be variables that are conditionally assigned to in the loop/region/sections. The variables in the *list* of a LASTPRIVATE clause that does *not* contain a CONDITIONAL modifier should be variables that are unconditionally assigned to in the loop or sections.

Subobjects that are not assigned a value by the last iteration of the DO or the lexically last SECTION of the SECTIONS directive are undefined after the construct.

The original variable becomes defined at the end of the construct if there is an implicit barrier at that point. To avoid race conditions, concurrent reads or updates of the original variable must be synchronized with the update of the original variable that occurs as a result of the LASTPRIVATE clause.

If the LASTPRIVATE clause is used in a construct for which NOWAIT is specified, accesses to the original variable may create a data race. To avoid this, synchronization must be inserted to ensure that the sequentially last iteration or lexically last section construct has stored and flushed that variable.

The following are restrictions for the LASTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that is private within a parallel region, or that appears in the REDUCTION clause of a PARALLEL construct, must not appear in a LASTPRIVATE clause on a worksharing construct if any of the corresponding worksharing regions ever binds to any of the corresponding parallel regions.
- A variable that appears in a LASTPRIVATE clause must be definable.
- An original variable with the ALLOCATABLE attribute must be in the allocated state at entry to the construct containing the LASTPRIVATE clause. The variable in the sequentially last iteration or lexically last section must be in the allocated state upon exit from that iteration or section with the same bounds as the corresponding original variable.
- Assumed-size arrays must not appear in a PRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
- If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

NOTE
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

NOTE
If a variable appears in a LASTPRIVATE clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a *map-type* of FROM.

Example

Consider the following:

```
!$OMP DO PRIVATE(I) LASTPRIVATE(B)
      DO I = 1, 1000
         B = I
      ENDDO
!$OMP END DO
```

In this case, after the construct is exited, variable B has the value 1000.

Consider the following:

```
!$OMP SECTIONS LASTPRIVATE(B)
!$OMP SECTION
      B = 2
!$OMP SECTION
      B = 4
!$OMP SECTION
      D = 6
!$OMP END SECTIONS
```

In this case the thread that executes the lexically last SECTION updates the original variable B to have a value of 4. However, variable D was not specified in the LASTPRIVATE clause, so it has an undefined value after the construct is exited.

Consider the following example:

```
      P = 0
!$OMP DO PRIVATE(I), FIRSTPRIVATE(P), LASTPRIVATE(CONDITIONAL:P)
      DO I = 1, 1000
         IF (A(I) .EQ. B) THEN
           P = I
           EXIT
         END IF
      ENDDO
!$OMP END DO
```

After the loop, P will be the index of the first element of A to match B; if no match is found, P will be zero.

PRIVATE Clause
FIRSTPRIVATE clause

LBOUND

Inquiry Intrinsic Function (Generic): *Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.*

Syntax

```
result = LBOUND (array [, dim] [, kind])
```

array	(Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer.
dim	(Input; optional) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank *array*.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *dim* is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of *array*. Each element in the result corresponds to a dimension of *array*.

If *array* is an array section or an array expression that is not a whole array or array structure component, each element of the result has the value 1.

If *array* is a whole array or array structure component, LBOUND (*array*, *dim*) has a value equal to the lower bound for subscript *dim* of *array*(if *dim* is nonzero or *array* is an assumed-size array of rank *dim*). Otherwise, the corresponding element of the result has the value 1.

If LBOUND is invoked for an assumed-rank object that is associated with a scalar and *dim* is absent, the result is a zero-sized array. LBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if *dim* is present because the rank of a scalar is zero and *dim* must be >= 1.

The setting of compiler options specifying integer size can affect this function.

Example

Consider the following:

```
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

LBOUND(ARRAY_A) is (1, 5). LBOUND(ARRAY_A, DIM=2) is 5.

LBOUND(ARRAY_B) is (2, -3). LBOUND(ARRAY_B (5:8, :)) is (1,1) because the arguments are array sections.

The following shows another example:

```
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = LBOUND (ar1)          ! returns [2, 4, -1]
res2 = LBOUND (ar1, DIM= 3)  ! returns -1
res3 = LBOUND (vec1)         ! returns [1]
END
```

See Also

UBOUND

LCOBOUND

Inquiry Intrinsic Function (Generic): *Returns the lower cobounds of a coarray.*

Syntax

```
result = LCOBOUND (coarray [,dim [, kind])
```

coarray	(Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.
dim	(Input; optional) Must be an integer scalar with a value in the range 1 <= *dim* <= *n*, where *n* is the corank of *coarray*. The corresponding actual argument must not be an optional dummy argument.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of default integer type. The result is scalar if *dim* is present; otherwise, the result is an array of rank one and size *n*, where*n* is the corank of *coarray*.

The result depends on whether *dim* is specified:

- If *dim* is specified, LCOBOUND (COARRAY, DIM) has a value equal to the lower cobound for cosubscript *dim* of *coarray*.
- If *dim* is not specified, LCOBOUND (COARRAY) has a value whose ith element is equal to LCOBOUND (COARRAY, i), for i = 1, 2,. . . , *n*, where *n* is the corank of *coarray*.

Example

If B is allocated by the statement ALLOCATE (B [2:3, 8:*]), then LCOBOUND (B) is [2, 8] and LCOBOUND (B, DIM=2) is 8.

LCWRQQ

Portability Subroutine: *Sets the value of the floating-point processor control word.*

Module

USE IFPORT

Syntax

```
CALL LCWRQQ (controlword)
```

controlword	(Input) INTEGER(2). Floating-point processor control word.

LCWRQQ performs the same function as the runtime subroutine SETCONTROLFPQQ and is provided for compatibility.

Example

```
USE IFPORT
INTEGER(2) control
CALL SCWRQQ(control) ! get control word
!  Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC)  ! Clear
                                             !  control word with inverse
                                             !  of rounding control mask
control = control .OR. FPCW$UP  ! Set control word
                                !  to round up
CALL LCWRQQ(control)
```

```
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END
```

See Also

SETCONTROLFPQQ

LEADZ

Elemental Intrinsic Function (Specific): *Returns the number of leading zero bits in an integer.*

Syntax

`result = LEADZ (i)`

i	(Input) Must be of type integer or logical.

Results

The result type is default integer. The result value is the number of leading zeros in the binary representation of the integer *i*.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

Consider the following:

```
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
  TYPE *, LEADZ(TWO**J)  ! Prints 64 down to 23 (leading zeros)
ENDDO
END
```

LEN

Inquiry Intrinsic Function (Generic): *Returns the length of a character expression.*

Syntax

`result = LEN (string [, kind])`

string	(Input) Must be of type character; it can be scalar or array valued. (It can be an array of strings.)
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters in *string*(if it is scalar) or in an element of *string*(if it is array valued).

Specific Name	Argument Type	Result Type
LEN [1]	CHARACTER	INTEGER(4)

Specific Name	Argument Type	Result Type
	CHARACTER	INTEGER(8)

[1]The setting of compiler options specifying integer size can affect this function.

Example

Consider the following example:

```
  CHARACTER (15) C (50)
  CHARACTER (25) D
```

LEN (C) has the value 15, and LEN (D) has the value 25.

The following shows another example:

```
CHARACTER(11) STR(100)
INTEGER I
I = LEN (STR)  ! returns 11
I = LEN('A phrase with 5 trailing blanks.^^^^^')
               ! returns 37
```

See Also

LEN_TRIM
Declaration Statements for Character Types
Character Data Type

LEN_TRIM

Elemental Intrinsic Function (Generic): *Returns the length of the character argument without counting trailing blank characters.*

Syntax

`result = LEN_TRIM (`*`string`* `[, `*`kind`*`])`

string	(Input) Must be of type character.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters remaining after any trailing blanks in *string* are removed. If the argument contains only blank characters, the result is zero.

The setting of compiler options specifying integer size can affect this function.

Example

LEN_TRIM (' C D ') has the value 4.

LEN_TRIM (' ') has the value 0.

The following shows another example:

```
INTEGER LEN1
LEN1 = LEN_TRIM (' GOOD DAY ') ! returns 9
LEN1 = LEN_TRIM (' ')          ! returns 0
```

LEN
LNBLNK

LGE

Elemental Intrinsic Function (Generic):
Determines if a string is lexically greater than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel© Fortran, LGE is equivalent to the (.GE.) operator.

Syntax

`result = LGE (string_a,string_b)`

string_a	(Input) Must be of type character.
string_b	(Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if *string_a* follows *string_b* in the ASCII collating sequence; otherwise, the result is false.

Specific Name	Argument Type	Result Type
LGE [1,2]	CHARACTER	LOGICAL(4)

[1] This specific function cannot be passed as an actual argument.

[2]The setting of compiler options specifying integer size can affect this function.

Example

LGE ('ONE', 'SIX') has the value false.

LGE ('TWO', 'THREE') has the value true.

The following shows another example:

```
LOGICAL L
L = LGE('ABC','ABD')       ! returns .FALSE.
L = LGE ('AB', 'AAAAAAAB') ! returns .TRUE.
```

LGT

Elemental Intrinsic Function (Generic):
Determines whether a string is lexically greater than another string, based on the ASCII collating sequence,

even if the processor's default collating sequence is different. In Intel® Fortran, LGT is equivalent to the > (.GT.) operator.

Syntax

`result = LGT (string_a,string_b)`

string_a	(Input) Must be of type character.
string_b	(Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if *string_a* follows *string_b* in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

Specific Name	Argument Type	Result Type
LGT [1,2]	CHARACTER	LOGICAL(4)

[1]This specific function cannot be passed as an actual argument.

[2]The setting of compiler options specifying integer size can affect this function.

Example

LGT ('TWO', 'THREE') has the value true.

LGT ('ONE', 'FOUR') has the value true.

The following shows another example:

```
LOGICAL L
L = LGT('ABC', 'ABC')  ! returns .FALSE.
L = LGT('ABC', 'AABC') ! returns .TRUE.
```

LINEAR Clause

Parallel Directive Clause: *Specifies that all variables in a list are private to a SIMD lane and that they have a linear relationship within the iteration space of a loop.*

Syntax

`LINEAR (linear-list [: linear-modifier [, linear-modifier]])`

-or deprecated form-

`LINEAR (old-linear-list[: linear-step])`

linear-list

Is a comma-separated list of one or more integer variables or dummy arguments. If the clause appears in a declarative directive, *linear-list* items must be dummy arguments of the procedure that will be invoked concurrently on each SIMD lane.

List items must be scalar and of type integer, unless the linear-modifier REF is specified, in which case list items can be dummy arguments of any type and rank. Each list item must comply with PRIVATE clause semantics.

List items cannot have the POINTER attribute or be Cray* pointers.

linear-modifier

Is *step-modifier* or *modifier*.

step-modifier

Is STEP (*linear-step*) or *linear-step*. *linear-step* must appear if STEP appears. If *step-modifier* is present, it must be the first (leftmost) *linear-modifer* specified.

linear-step

Is a compile-time positive, integer, scalar constant expression. If *linear-step* is not specified, it is assumed to be 1.

modifier

Is one of the following:

- REF

  Specifies that the storage location of each *linear-list* item on each lane corresponds to an array at the storage location upon entry to the function indexed by the logical number of the lane times *linear-step*. The REF modifier can only appear in a LINEAR clause of a declarative directive.

  The referenced values passed into the routine (which forms a vector for calculations) are located sequentially, like in an array, with the distance between elements equal to *linear-step*.

  This modifier can be used only for dummy arrays passed by reference. The dummy arrays can be explicit shape or assumed shape, and they can have the ALLOCATABLE attribute.
- VAL

  Specifies that the value of each *linear-list* item on each lane corresponds to the value of the *linear-list* item upon entry to the function plus the logical number of the lane times *linear-step*.

  On each iteration of the loop from which the routine is called, the value of the parameter can be calculated as (value_on_previous_iteration + *linear-step*).
- UVAL

  Similar to VAL, but each invocation uses the same storage location for each SIMD lane. This storage location is updated with the final value of the logically last lane. It differs from VAL as follows:

  - For VAL, a vector of addresses (references) is passed to the vector variant of the routine.
  - For UVAL, only one address (reference) is passed, which may improve performance.

  This modifier can be used only for dummy arguments passed by reference. A UVAL modifier can only appear in a LINEAR clause of a declarative directive.

If *modifier* is not specified or it is VAL or UVAL, the value of each *linear-list* item on each lane corresponds to the value of the *linear-list* item upon entry to the function plus the logical number of the lane times *linear-step*.

You can only use REF or VAL if the *linear-list* item is a dummy argument without the Fortran Standard VALUE attribute.

old-linear-list

Is one of the following:

- *linear-list*
- *modifier* (*linear-list*)

A LINEAR clause can specify at most one *step-modifier* and one *modifier*. Multiple LINEAR clauses can be used to specify different values for *linear-step* and/or *modifier*s. The *linear-step* expression must be invariant (must not be changed) during the execution of the associated construct. Multiple LINEAR clauses are merged as a union.

The value of the *linear-list* item on a given iteration is equal to the value of the original list item plus the logical number of the iteration times *linear-step*. The value corresponding to the sequentially last iteration of the associated loops is assigned to the original *linear-list* item. If modifier is not REF and the *linear-list* item has the ALLOCATABLE attribute, in the sequentially last iteration the allocation status of the *linear-list* item must be allocated upon completion of that iteration.

A *linear-list* item in a LINEAR clause cannot appear in any other data scope attribute clause, in another LINEAR clause in the same directive, or more than once in *linear-list*. For a list of data scope attribute clauses, see the first table in Clauses Used in Multiple OpenMP* Fortran Directives.

If a *linear-list* item is a dummy argument without the Fortran Standard VALUE attribute and the REF modifier is not specified, then a read of the *linear-list* item must be executed before any writes to the *linear-list* item.

If a LINEAR clause appears in a directive that also contains a REDUCTION clause with the INSCAN modifier, only a loop iteration variable of a loop associated with the construct can appear as a *linear-list* item in the LINEAR clause.

The REF modifier is very important because Fortran passes dummy arguments by reference. By default, the compiler places consecutive addresses in a vector register, which leads to an inefficient gather of the addresses.

In the following example, `linear(x, y:ref)` tells the compiler that the 4 addresses for the dummy argument `x` are consecutive, and the 4 addresses for the dummy argument `y` are consecutive, so the code only needs to dereference `x` and `y` once each and then copy consecutive values to vector registers.

```
subroutine test_linear(x, y)
!$omp declare simd (test_linear) linear(x, y:ref)    ! arguments by reference
    real(8),intent(in)  :: x(4)
    real(8),intent(out) :: y(4)
    y = 1. + sin(x)**3
end subroutine test_linear
…                               ! procedure that calls test_linear
interface                       ! test_linear needs an explicit interface
…
do j = 1,n
     call test_linear(a(j), b(j))    ! loop vectorized via qopenmp-simd
enddo
…
```

Example

Consider the following:

```
! universal but slowest definition; it matches the use of func in loops 1, 2, and 3:
!$OMP DECLARE SIMD
!
! matches the use of func in loop 1:
!$OMP DECLARE SIMD LINEAR(in1) LINEAR (in2: REF) UNIFORM(mul)
!
! matches the use of func in loops 2 and 3:
!$OMP DECLARE SIMD LINEAR (in2: REF)
!
! matches the use of func in loop 2:
!$OMP DECLARE SIMD LINEAR (in2: REF) LINEAR(mul)
!
! matches the use of func in loop 3:
!$OMP DECLARE SIMD LINEAR (in2: STEP(2), VAL)

function func(in1, in2, mul)
integral   in1
integral   in2
integral   mul
...
integral a, k
integral b(100)
integral c(100)
integral ndx(100)
...
```

The following are the loop examples referenced above.

```
!loop 1
!$OMP SIMD
   DO i=1,100
      c(i) = func(a + i, b(i), mul) ! the value of the 1st parameter is changed linearly,
                                    !   the 2nd parameter reference is changed linearly,
                                    !   the 3rd parameter is not changed
   END DO

!loop 2
!$OMP SIMD
   DO i=1,100
      c(i) = func(b(ndx(i)), b(i), i + 1 ! the value of the 1st parameter is unpredictable,
                                         !   the 2nd reference is changed linearly,
                                         !   the 3rd parameter is changed linearly
   END DO

!loop 3
!$OMP SIMD
   DO i=1,100
      k = i * 2                       ! during vectorization, private variables are
      c(i) = func(b(ndx(i)), k, b(i)) !     transformed into arrays: k -> k_vec(simdlen)
                                      ! the value of the 1st parameter is unpredictable,
                                      ! for the 2nd parameter both value and reference
                                      !     to its location can be considered linear,
                                      ! the value for the 3rd parameter is unpredictable
                                      !
                                      ! the !$OMP DECLARE SIMD LINEAR(VAL(in2:2))) will
   END DO                             !     be chosen from the two matching variants)
```

LLE

Elemental Intrinsic Function (Generic):
Determines whether a string is lexically less than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LLE is equivalent to the (.LE.) operator.

Syntax

`result = LLE (string_a,string_b)`

string_a	(Input) Must be of type character.
string_b	(Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if *string_a* precedes *string_b* in the ASCII collating sequence; otherwise, the result is false.

Specific Name	Argument Type	Result Type
LLE [1,2]	CHARACTER	LOGICAL(4)

[1]This specific function cannot be passed as an actual argument.

[2]The setting of compiler options specifying integer size can affect this function.

Example

LLE ('TWO', 'THREE') has the value false.

LLE ('ONE', 'FOUR') has the value false.

The following shows another example:

```
LOGICAL L
L = LLE('ABC', 'ABC')   ! returns .TRUE.
L = LLE('ABC', 'AABCD') ! returns .FALSE.
```

LLT

Elemental Intrinsic Function (Generic):
Determines whether a string is lexically less than another string, based on the ASCII collating sequence,

even if the processor's default collating sequence is different. In Intel® Fortran, LLT is equivalent to the < (.LT.) operator.

Syntax

```
result = LLT (string_a,string_b)
```

string_a	(Input) Must be of type character.
string_b	(Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if *string_a* precedes *string_b* in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

Specific Name	Argument Type	Result Type
LLT [1,2]	CHARACTER	LOGICAL(4)

[1]This specific function cannot be passed as an actual argument.

[2]The setting of compiler options specifying integer size can affect this function.

Example

LLT ('ONE', 'SIX') has the value true.

LLT ('ONE', 'FOUR') has the value false.

The following shows another example:

```
LOGICAL L
L = LLT ('ABC', 'ABC')     ! returns .FALSE.
L = LLT ('AAXYZ', 'ABCDE') ! returns .TRUE.
```

LNBLNK

Portability Function: *Locates the position of the last nonblank character in a string.*

Module

USE IFPORT

Syntax

```
result = LNBLNK (string)
```

string	(Input) Character*(*). String to be searched. Cannot be an array.

Results

The result type is INTEGER(4). The result is the index of the last nonblank character in *string*.

LNBLNK is very similar to the intrinsic function LEN_TRIM, except that *string* cannot be an array.

Example

```
USE IFPORT
integer(4) p
p = LNBLNK(' GOOD DAY ') ! returns 9
p = LNBLNK(' ')          ! returns 0
```

See Also

LEN_TRIM

LOC

Inquiry Intrinsic Function (Generic): *Returns the internal address of a storage item. This function cannot be passed as an actual argument.*

Syntax

```
result = LOC (x)
```

x	(Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the %LOC built-in function.

Example

The Fortran standard provides the C_LOC intrinsic module function as an alternative to the non-standard LOC. For more information, see the descriptions of C_LOC, C_FUNLOC, C_F_POINTER and C_F_PROCPOINTER.

```
! Example of using the LOC intrinsic
integer :: array(2) = [10,20]
integer :: t
pointer (p,t) ! Integer pointer extension
                ! p is pointer, t is pointee (target)
                ! This declares p as an address-sized integer

p = loc(array(1)) ! Address of array(1)
print *, t          ! Prints 10
p = loc(array(2)) ! Address of array(2)
print *, t          ! Prints 20
```

%LOC

Built-in Function: *Computes the internal address of a storage item.*

Syntax

```
result = %LOC (a)
```

a	(Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Description

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the LOC intrinsic function.

LOCK and UNLOCK

Statements: *A LOCK statement causes a lock variable to become locked by an image. An UNLOCK statement causes the lock variable to become unlocked. They take the following forms:*

Syntax

```
LOCK (lock-var [, ACQUIRED_LOCK=log-var] [, STAT=stat-var] [, ERRMSG=err-var])
```

```
UNLOCK (lock-var [, STAT=stat-var] [, ERRMSG=err-var])
```

lock-var	Is a scalar variable of type LOCK_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.
log-var	Is a scalar logical variable.
stat-var	Is a scalar integer variable in which the status of the synchronization is stored.
err-var	Is a scalar default character variable in which explanatory text is stored if an error occurs.

ACQUIRED_LOCK=, STAT=, and ERRMSG= can appear in any order, but only once in a LOCK statement.

STAT= and ERRMSG= can appear in either order, but only once in an UNLOCK statement.

Description

A lock variable is unlocked if its value is equal to that of the structure constructor LOCK_TYPE ( ). If it has any other value, it is locked.

A lock variable is locked by an image if it was locked by execution of a LOCK statement on that image and has not been subsequently unlocked by execution of an UNLOCK statement on the same image.

When a LOCK statement is specified without an ACQUIRED_LOCK= specifier, it causes the lock variable to become locked by that image. If the lock variable is already locked by another image, that LOCK statement causes the lock variable to become defined after the other image causes the lock variable to become unlocked.

If the lock variable is unlocked, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier causes the lock variable to become locked by that image and the *log-var* to become defined with the value TRUE. If the lock variable is already locked by a different image, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier leaves the lock variable unchanged and causes the *log-var* to become defined with the value FALSE.

During the execution of the program, the value of a lock variable changes through a sequence of locked and unlocked states when LOCK and UNLOCK statements are executed. If a lock variable becomes unlocked by execution of an UNLOCK statement on image M and next becomes locked by execution of a LOCK statement

on image T, the segments preceding the UNLOCK statement on image M precede the segments following the LOCK statement on image T. Execution of a LOCK statement that does not cause the lock variable to become locked does not affect segment ordering.

An error condition occurs in the following cases:

- If the lock variable in a LOCK statement is already locked by the executing image
- If the lock variable in an UNLOCK statement is not already locked by the executing image

If an error condition occurs during execution of a LOCK or UNLOCK statement, the value of the lock variable is not changed and the value of the ACQUIRED_LOCK variable, if any, is not changed.

Example

The following example shows the use of LOCK and UNLOCK statements to manage a work queue:

```
USE, INTRINSIC :: ISO_FORTRAN_ENV

TYPE(Task) :: work_queue(50)[*]          ! List of tasks on queue to perform
INTEGER :: work_queue_size[*]
TYPE(LOCK_TYPE) :: work_queue_lock[*]    ! Lock to manage the work queue

TYPE(Task) :: current_task
INTEGER :: my_image

my_image = THIS_IMAGE()
DO
   ! Process the next task in the work queue
   LOCK (work_queue_lock)              ! Start of new segment A
   ! Segment A is ordered with respect to segment B
   ! executed by image my_image-1 below because of lock exclusion
   IF (work_queue_size>0) THEN
       ! Get the next job from the queue
       current_task = work_queue(work_queue_size)
       work_queue_size = work_queue_size-1
   END IF
   UNLOCK (work_queue_lock) ! Segment ends
...
   ! Process the task

   ! Add a new task on the neighboring queue:
   LOCK(work_queue_lock[my_image+1])      ! Starts segment B
   ! Segment B is ordered with respect to segment A
   ! executed by image my_image+1 above because of lock exclusion
   IF (work_queue_size[my_image+1]<SIZE(work_queue)) THEN
       work_queue_size[my_image+1] = work_queue_size[ti+1]+1
       work_queue(work_queue_size[my_image+1])[my_image+1] = current_task
   END IF
   UNLOCK (work_queue_lock[my_image+1]) ! Ends segment B
END DO
```

LOG

Elemental Intrinsic Function (Generic): *Returns the natural logarithm of the argument.*

Syntax

```
result = LOG (x)
```

x	(Input) Must be of type real or complex. If *x* is real, its value must be greater than zero. If *x* is complex, its value must not be zero.

Results

The result type and kind are the same as *x*. The result value is approximately equal to $\log_e x$.

If the arguments are complex, the result is the principal value with imaginary part omega in the range -pi <= omega <= pi.

If the real part of *x* < 0 and the imaginary part of *x* is a positive real zero, the imaginary part of the result is pi.

If the real part of *x* < 0 and the imaginary part of *x* is a negative real zero, the imaginary part of the result is -pi.

Specific Name	Argument Type	Result Type
ALOG [1,2]	REAL(4)	REAL(4)
DLOG	REAL(8)	REAL(8)
QLOG	REAL(16)	REAL(16)
CLOG [2]	COMPLEX(4)	COMPLEX(4)
CDLOG[3,4]	COMPLEX(8)	COMPLEX(8)
CQLOG	COMPLEX(16)	COMPLEX(16)

[1]This function is treated like LOG.

[2]The setting of compiler options specifying real size can affect ALOG, LOG, and CLOG.

[3]This function can also be specified as ZLOG.

[4]The setting of compiler options specifying double size can affect CDLOG.

Example

LOG (8.0) has the value 2.079442.

LOG (25.0) has the value 3.218876.

The following shows another example:

```
REAL r
r = LOG(10.0)  ! returns 2.302585
```

See Also

EXP

LOG10

LOG_GAMMA

Elemental Intrinsic Function (Generic): *Returns the logarithm of the absolute value of the gamma function of the argument.*

Syntax

```
result = LOG_GAMMA (x)
```

x	(Input) Must be of type real. It must not be zero or a negative integer.

Results

The result type and kind are the same as *x*.

The result has a value equal to a processor-dependent approximation to the natural logarithm of the absolute value of the gamma function of *x*.

Example

LOG_GAMMA (3.0) has the approximate value 0.693.

LOG10

Elemental Intrinsic Function (Generic): *Returns the common logarithm of the argument.*

Syntax

```
result = LOG10 (x)
```

x	(Input) Must be of type real or complex. If *x* is real, its value must be greater than zero. If *x* is complex, its value must not be zero.

Results

The result type and kind are the same as *x*. The result value is approximately equal to $\log_{10}x$.

Specific Name	Argument Type	Result Type
ALOG10 [1,2]	REAL(4)	REAL(4)
DLOG10 [3]	REAL(8)	REAL(8)
QLOG10	REAL(16)	REAL(16)
CLOG10[2]	COMPLEX(4)	COMPLEX(4)
CDLOG10[3]	COMPLEX(8)	COMPLEX(8)
CQLOG10	COMPLEX(16)	COMPLEX(16)

[1]This function is treated like LOG10.

[2]The setting of compiler options specifying real size can affect ALOG10, CLOG10, and LOG10.

[3]The setting of compiler options specifying double size can affect DLOG10 and CDLOG10.

Example

LOG10 (8.0) has the value 0.9030900.

LOG10 (15.0) has the value 1.176091.

The following shows another example:

```
REAL r
r = LOG10(10.0)  ! returns 1.0
```

See Also

LOG

LOGICAL Function

Elemental Intrinsic Function (Generic): *Converts the logical value of the argument to a logical value with different kind parameters.*

Syntax

`result = LOGICAL (l[,kind])`

l	(Input) Must be of type logical.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is of type logical. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of default logical. The result value is that of *l*.

The setting of compiler options specifying integer size can affect this function.

Example

LOGICAL (L .OR. .NOT. L) has the value true and is of type default logical regardless of the kind parameter of logical variable L.

LOGICAL (.FALSE., 2) has the value false, with the parameter of kind 2.

See Also

CMPLX
INT
REAL
Logical Data Types

LOGICAL Statement

Statement: *Specifies the LOGICAL data type.*

Syntax

`LOGICAL`

`LOGICAL([KIND=] n)`

`LOGICAL*n`

n	Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

Example

```
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (2), SAVE :: doit, dont=.FALSE.
LOGICAL switch
```

```
! An equivalent declaration is:
LOGICAL flag1, flag2
LOGICAL (2) doit, dont=.FALSE.
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

LONG

Portability Function: *Converts an INTEGER(2) argument to INTEGER(4) type.*

Module

USE IFPORT

Syntax

`result = LONG (int2)`

int2 (Input) INTEGER(2). Value to be converted.

Results

The result type is INTEGER(4). The result is the value of *int2* with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to *int2*.

INT
KIND

LOOP

OpenMP* Fortran Compiler Directive: *Specifies that the iterations of the associated loops can execute concurrently. This feature is only available for ifx.*

Syntax

```
!$OMP LOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END LOOP]
```

clause Is one of the following:

- BIND (*binding*)

  Determines the binding region of the construct. *binding* is `teams`, `parallel`, or `thread`.

If `teams` is specified, and an innermost enclosing teams region exists, the binding region is that innermost teams region. If `parallel` is specified, the binding region is the innermost enclosing parallel region. It may be an implicit parallel region. If `thread` is specified, the binding region is not defined.

If the BIND clause does not appear and the construct is enclosed in a teams or parallel region, the binding region is the innermost enclosing team or parallel region. If no `teams` or `parallel` region encloses the loop construct, the binding region is undefined.

If the binding region is a `parallel` region, the binding thread set is the set of threads executing the parallel region. If the binding region is a `teams` region, the biding thread set is the set of primary threads executing the region. If the binding region is not defined, the binding thread is the encountering thread.

- COLLAPSE (n)

  For *n*, a value greater than 1 tells the compiler the number of associated loops to collapse into a larger iterations space, which executes without ordering.The associated loop nest must not contain any OpenMP* directives between associated loops in the nest.

  If no COLLAPSE clause appears, or if it appears with a value of 1 for *n*, only the outermost loop is associated with the LOOP construct.

  At most one COLLAPSE clause is permitted on a LOOP directive.
- LASTPRIVATE ([CONDITIONAL:] list)

  Only a loop iteration variable of a loop associated with the LOOP construct may appear as a list item in a LASTPRIVATE clause.
- ORDER ([order-modifier :] CONCURRENT) (ifx only)
- PRIVATE (list)
- REDUCTION ([DEFAULT,] reduction-identifier : list)

do-loop

Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical loop form.

They cannot be DO WHILE loops or loops without loop control. You cannot branch out of a DO loop associated with a LOOP directive. CYCLE and EXIT statements are not permitted. The *do-loop* can be a DO CONCURRENT loop.

The LOOP construct tells the compiler that all iterations of the associated loops can execute concurrently or in any order.

Data sharing clauses and the COLLAPSE clause are not permitted if *do-loop* is a DO CONCURRENT loop. Data sharing attributes for DO CONCURRENT loops are determined by *locality-spec*s in the DO CONCURRENT statement. In a DO CONCURRENT loop associated with a LOOP directive, if a variable is referenced in more than one iteration of the DO CONCURRENT loop, and is modified in at least one iteration, the variable must appear in a *locality-spec* in the DO CONCURRENT statement.

If used, the END LOOP directive must appear immediately after the end of the loop. If you do not specify an END LOOP directive, an END LOOP directive is assumed at the end of the outermost associated *do-loop*.

A LOOP construct can not contain calls to procedures containing other OpenMP* constructs or calls to the OpenMP* runtime library functions.

The only OpenMP* constructs permitted inside a LOOP construct are another LOOP, PARALLEL, or SIMD construct or a combined construct whose leftmost construct is a PARALLEL construct.

A LOOP construct that appears in a procedure and is not nested inside another OpenMP* construct must contain a BIND clause.

If more than one loop is associated with the construct, any intervening code between two associated loops executes at least once per iteration of the loop containing the intervening code, and at most once per execution of the innermost loop associated with the construct. If an associated loop has a trip count of zero and that loop does not contain the intervening code, the behavior is undefined.

The set of threads that may execute iterations of the LOOP construct is the binding thread set. Each iteration is executed by one of these threads.

If a loop region is bound to a `teams` region, the threads in the binding set can continue execution at the end of the loop region without waiting for all iterations of the region to complete execution. All iterations of the loop region must complete execution before the end of the `teams` region. If the binding region is not a `teams` region, all iterations of the associated loops must complete execution before the loop region is exited.

If a loop region is bound to a `teams` or `parallel` region, it must be encountered by all or none of the binding threads.

A LOOP construct with a BIND clause that specifies a value of teams must be strictly nested inside a `teams` region. The behavior of a LOOP construct with a BIND clause specifying a value of `parallel` is undefined if the loop construct is nested inside a SIMD construct.

Referencing a THREADPRIVATE variable in a LOOP construct results in undefined behavior.

If a *reduction-modifier* is present in a reduction clause, the only permitted value is DEFAULT.

Example

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END LOOP directive is optional. Iterations of the do loop can execute in any order, or concurrently.

```
  !$OMP PARALLEL
  !$OMP LOOP
        DO I=1,N
          B(I) = (A(I) + A(I-1)) / 2.0
        END DO
  !$OMP END LOOP
  !$OMP END PARALLEL
```

In the next example, the loops over J1 and J2 are collapsed and their iteration space is executed by all threads of the current team. The subroutine BAR referenced in the innermost loop cannot contain OpenMP* constructs or calls to procedures that do, and it cannot contain calls to the OpenMP* runtime library. The END LOOP directive is optional:

```
!$OMP LOOP COLLAPSE(2) PRIVATE(J1, J2, J3)
    DO J1 = J1_L, J1_U, J1_S
        DO J2 = J2_L, J2_U, J2_S
            DO J3 = J3_L, J3_U, J3_S
                CALL BAR(A, J1, J2, J3)
            ENDDO
        ENDDO
    ENDDO
!$OMP END LOOP
```

LOOP COUNT

General Compiler Directive: *Specifies the iterations (typical trip count) for a DO loop.*

Syntax

```
!DIR$ LOOP COUNT (n1[, n2]...)
!DIR$ LOOP COUNT= n1[, n2]...
!DIR$ LOOP COUNT qualifier(n)[, qualifier(n)]...
!DIR$ LOOP COUNT qualifier=n[, qualifier=n]...
```

n1, *n2*
Is a non-negative integer constant. It indicates that the next DO loop will iterate *n1*, *n2*, or some other number of times.

qualifier
Is one or more of the following:

- MAX - specifies the maximum loop trip count.
- MIN - specifies the minimum loop trip count.
- AVG - specifies the average loop trip count.

The value of the loop count affects heuristics used in software pipelining, vectorization, and loop-transformations.

There is no check at runtime to determine if the MAX or MIN values are exceeded.

Example

Consider the following:

```
!DIR$ LOOP COUNT (10000)
do i =1,m
b(i) = a(i) +1 ! This is likely to enable the loop to get software-pipelined
enddo
```

Note that you can specify more than one LOOP COUNT directive for a DO loop. For example, the following directives are valid:

```
!DIR$ LOOP COUNT (10, 20, 30)
!DIR$ LOOP COUNT MAX=100, MIN=3, AVG=17
DO
...
```

Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements

LSHIFT

Elemental Intrinsic Function (Generic): *Shifts the bits in an integer left by a specified number of positions. This is the same as specifying ISHFT with a positive shift.*

See Also
See ISHFT.

LSTAT
Portability Function: *Returns detailed information about a file.*

Module
USE IFPORT

Syntax
`result = LSTAT (name,statb)`

name	(Input) Character*(*). Name of the file to examine.
statb	(Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See STAT for the possible values returned in *statb*.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see IERRNO).

LSTAT returns detailed information about the file named in *name*.

On Linux* systems, if the file denoted by *name* is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function.

INQUIRE also provides information about file properties.

Example
```
USE IFPORT
INTEGER(4) info_array(12), istatus
character*20 file_name
print *, "Enter name of file to examime: "
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
   print *, info_array
else
   print *, 'Error ',istatus
end if
```

See Also
INQUIRE
GETFILEINFOQQ
STAT
FSTAT

LTIME
Portability Subroutine: *Returns the components of the local time zone time in a nine-element array.*

Module
USE IFPORT

Syntax

CALL LTIME (*time*,*array*)

time (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

array (Output) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from *time*.

The elements of *array* are returned as follows:

Element	Value
array(1)	Seconds (0 - 59)
array(2)	Minutes (0 - 59)
array(3)	Hours (0 - 23)
array(4)	Day of month (1 - 31)
array(5)	Month (0 - 11)
array(6)	Years since 1900
array(7)	Day of week (0 - 6, where 0 is Sunday)
array(8)	Day of year (1 - 365)
array(9)	1 if daylight saving time is in effect; otherwise, 0.

Caution
This subroutine is not year-2000 compliant, use DATE_AND_TIME instead.

On Linux*, *time* can be a negative number returning the time before 00:00:00 Greenwich mean time, January 1, 1970.

On Windows*, *time* can not be negative, in which case all 9 elements of *array* are set to -1.

On all operating systems, if there is a system error in getting the local time, all 9 elements of *array* are set to -1.

Example

```
USE IFPORT
INTEGER(4) input_time, time_array(9)
!   find number of seconds since 1/1/70
input_time=TIME()
!   convert number of seconds to time array
CALL LTIME (input_time, time_array)
PRINT *, time_array
```

DATE_AND_TIME

M to N

This section describes language features that start with M or N.

M to N

MAKEDIRQQ

Portability Function: *Creates a new directory with a specified name.*

Module

USE IFPORT

Syntax

`result = MAKEDIRQQ (dirname)`

dirname	(Input) Character*(*). Name of directory to be created.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or backslash (\) as valid delimiters.

If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:

- ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- ERR$EXIST - The directory already exists.
- ERR$NOENT - The file or path specified was not found.

Example

```
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ('mynewdir')
IF (result) THEN
   WRITE (*,*) 'New subdirectory successfully created'
ELSE
   WRITE (*,*) 'Failed to create subdirectory'
END IF
END
```

GETLASTERRORQQ

MALLOC

Elemental Intrinsic Function (Generic): *Allocates a block of memory. This is a generic function that has no specific function associated with it. It must not be passed as an actual argument.*

Syntax

`result = MALLOC (size)`

size (Input) Must be of type integer. This value is the size (in bytes) of memory to be allocated.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the starting address of the allocated memory. The memory allocated can be freed by using the FREE intrinsic function.

Example

```
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE)     ! ADDR will point to STORAGE
SIZE = 1024                 ! Size in bytes
ADDR = MALLOC(SIZE)         ! Allocate the memory
CALL FREE(ADDR)             ! Free it
```

MAP Clause

Parallel Directive Clause: *Maps a variable from the data environment of the current task to the data environment of the device associated with the construct. This clause only applies to certain TARGET directives. This feature is only available for ifx.*

Syntax

MAP ([[*map-type-modifier*[,]] *map-type* :] *list*)

map-type-modifier Is one of the following:

ALWAYS — Specifies that initialization should always occur for the *list* items.

CLOSE — Suggests to the runtime system to allocate memory close to the target device.

MAPPER (*mapper-identifier*) — Specifies the name of an accessible user-defined mapper declared in a DECLARE MAPPER directive. If MAPPER is not present, it is as if MAPPER (DEFAULT) were specified.

The map behavior of a list item in a MAP clause with the same type as the type specified in the user-defined mapper is modified by a user-defined mapper.

If a list item does not also appear as a list item in a MAP clause with the PRESENT map-type-modifier in the same directive, the effect is to remove the list item from the MAP clause and apply the clauses specified in the user-defined mapper to the construct where the MAP clause appears.

References to *var* in the DECLARE MAPPER MAP clauses are replaced by the list item, and the map type is replaced with the final map type as determined by the table of final map types (see DECLARE MAPPER).

`PRESENT` — Causes an error to occur and program termination if any list item in the clause does not appear in the device data environment.

When the PRESENT *map-type-modifier* appears in a MAP clause, it takes precedence over all other MAP clauses in a directive. The behavior is as if the MAP clause specifying PRESENT appears lexically before any other MAP clauses in the directive.

`map-type` — Determines how a *list* item is initialized. Possible values are:

`ALLOC` — On entry to the outermost device region, each new corresponding list item has an undefined initial value.

`DELETE` — On exit from the device region, if the corresponding list item is present on the device, it is then deleted from the device.

`FROM` — On exit from the device region, the value of the corresponding list item is assigned to each original list item.

This is ignored for nested regions unless *map-type-modifier* ALWAYS is specified.

`RELEASE` — On exit from the outermost device region, the corresponding list item is deleted from the device.

`TO` — On entry to the device region, each new corresponding list item is initialized with the value of the original list item.

This is ignored for nested regions unless *map-type-modifier* ALWAYS is specified.

`TOFROM` — On entry to the device region, each new corresponding list item is initialized with the value of the original list item. On exit from the device region, the value of the corresponding list item is assigned to each original list item.

This is ignored for nested regions unless *map-type-modifier* ALWAYS is specified.

If a *map-type* is not specified, the default is TOFROM.

The map initialization and assignment are done as if by intrinsic assignment, that is, through bitwise copy.

list	Is the name of one or more variables, array sections, or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /). If a *list* item is an array section, it must specify contiguous storage. A *list* item can appear in at most one of the TO, FROM, or TOFROM clauses. If a *list* item appears in an ALLOC clause, it cannot appear on a TO or TOFROM clause.

On entry to an outermost target region where this clause is used, for each original list item, a new corresponding list item is created on the device. On exit from the outermost target region, if the corresponding list item is present on the device, it is then deleted from the device.

At least one MAP clause must appear in a directive that allows the clause.

THREADPRIVATE variables cannot appear in a MAP clause.

For the TARGET ENTER DATA directive, *map-type* must be either TO or ALLOC.

For the TARGET EXIT DATA directive, *map-type* must be FROM, RELEASE, or DELETE.

For the TARGET and TARGET DATA directives, *map-type* must be TO, FROM, TOFROM, or ALLOC.

For the TARGET UPDATE directive, *map-type* must be TO or FROM.

If original and corresponding list items share storage, data races can result when intervening synchronization between tasks does not occur. If variables that share storage are mapped, it causes unspecified behavior.

Any variables within a TARGET MAP region that are not specified in a MAP clause are treated as shared variables within the region.

A list item must not contain any components that have the ALLOCATABLE attribute.

If the allocation status of a list item with the ALLOCATABLE attribute is unallocated upon entry to a target region, the list item must be unallocated upon exit from the region.

If the allocation status of a list item with the ALLOCATABLE attribute is allocated upon entry to a target region, the allocation status of the corresponding list item must not be changed and must not be reshaped in the region.

If an array section of an allocatable array is mapped and the size of the section is smaller than that of the whole array, the target region must not have any reference to the whole array.

A list item that is an array or an array section that has a type for which a user-defined mapper exists, is mapped as if the final map type is ALLOC, RELEASE, or DELETE. Then each element is mapped with the original map type, as if by a separate construct according to the user-defined mapper.

If a MAPPER *map-type-modifier* appears in the MAP clause, the type specified in the user-defined mapper must match the type of the list items in the MAP clause.

TARGET directive clause DEFAULTMAP
DECLARE MAPPER Directive

MAP and END MAP

Statement: *Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration.*

Example

```
UNION
  MAP
     CHARACTER*20 string
  END MAP
  MAP
     INTEGER*2 number(10)
  END MAP
END UNION

UNION
  MAP
     RECORD /Cartesian/ xcoord, ycoord
  END MAP
  MAP
     RECORD /Polar/ length, angle
  END MAP
END UNION
```

See Also

See STRUCTURE.

MASKED

OpenMP* Fortran Compiler Directive: *Specifies a structured block to be executed by a subset of the threads of the current team. This feature is only available for ifx.*

Syntax

```
!$OMP MASKED [clause]
   loosely-structured-block
!$OMP END MASKED
-or-
!$OMP MASKED [clause]
   strictly-structured-block
[!$OMP END MASKED]
```

clause

Is FILTER (*thread_num*), where *thread_num* is a scalar integer expression. The clause is optional and may appear at most once.

A thread that encounters a MASKED construct with a FILTER clause executes the block of the construct if its thread number matches the value of *thread_num* specified in the FILTER clause. Otherwise, the thread skips the block of code and continues execution after the MASKED construct. *thread_num* can be a variable expression, so the value of *thread_num* can vary across threads.

If the FILTER clause is not present, it is as if FILTER (0) has been specified. In this case, only the primary thread executes the enclosed block.

loosely-structured-block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a MASKED construct is the current team. A master region binds to the innermost enclosing parallel region.

There is no implied barrier, either on entry to or exit from the masked section.

Examples

The following example forces the primary thread to execute the routines OUTPUT and INPUT:

```
!$OMP PARALLEL DEFAULT(SHARED)
      CALL WORK(X)
!$OMP MASKED
! The above line is equivalent to MASKED FILTER(0)
      CALL OUTPUT(X)
      CALL INPUT(Y)
!$OMP END MASKED
      CALL WORK(Y)
!$OMP END PARALLEL
```

In the following example, only the even numbered threads execute INPUT and OUTPUT:

```
!$OMP PARALLEL
  BLOCK
    INTEGER :: me = omp_get_thread_num
      CALL WORK(X)
!$OMP MASKED FILTER (me + mod (me,2))
      CALL OUTPUT(X)
      CALL INPUT(Y)
!$OMP END MASKED
      CALL WORK(Y)
  END BLOCK
!$OMP END PARALLEL
```

MASKED TASKLOOP

OpenMP* Fortran Compiler Directive: *Creates a MASKED construct containing a TASKLOOP construct, with no Fortran statements in the MASKED construct that are not also in the TASKLOOP construct. This feature is only available for ifx.*

Syntax

```
!$OMP MASKED TASKLOOP [clause[[,] clause]... ]
   loop-nest
[!$OMP END MASKED TASKLOOP]
```

clause	Can be any of the clauses accepted by the MASKED or TASKLOOP directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a MASKED construct with a TASKLOOP construct nested inside of it. The semantics are identical to a TASKLOOP construct specified immediately after a MASKED construct.

All restrictions for MASKED and TASKLOOP constructs apply to this combined construct.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
MASKED directive
TASKLOOP directive

To learn more about canonical form loops, see the OpenMP* specification.

MASKED TASKLOOP SIMD

OpenMP* Fortran Compiler Directive: *Creates a MASKED construct containing a TASKLOOP SIMD construct, with no Fortran statements in the MASKED construct that are not also in the TASKLOOP SIMD construct. This feature is only available for ifx.*

Syntax

```
!$OMP MASKED TASKLOOP SIMD [clause[[,] clause]... ]
   loop-nest
[!$OMP END MASKED TASKLOOP SIMD]
```

clause	Can be any of the clauses accepted by the MASKED or TASKLOOP SIMD directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a MASKED construct with a TASKLOOP SIMD construct nested inside of it. The semantics are identical to a TASKLOOP SIMD construct specified immediately after a MASKED construct.

All restrictions for MASKED and TASKLOOP SIMD constructs apply to this combined construct.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
MASKED directive
TASKLOOP SIMD directive

To learn more about canonical form loops, see the OpenMP* specification.

MASKL

Elemental Intrinsic Function (Generic): *Returns a left-justified mask.*

Syntax

```
result = MASKL (i[,kind])
```

i	(Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits *s* of the model integer defined for bit manipulation contexts.

kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its leftmost I bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

Example

MASKL (3) has the value SHIFTL (7, BIT_SIZE (0) - 3).

See Also

MASKR

MASKR

Elemental Intrinsic Function (Generic): *Returns a right-justified mask.*

Syntax

```
result = MASKR (i[,kind])
```

i	(Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits *s* of the model integer defined for bit manipulation contexts.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its rightmost I bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

Example

MASKR (3) has the value 7.

See Also

MASKL

MASTER

OpenMP* Fortran Compiler Directive:
(Deprecated; see MASKED) Specifies a block of code to be executed by the master thread of the team.

Syntax

```
!$OMP MASTER
   loosely-structured-block
!$OMP END MASTER
```

```
-or-
!$OMP MASTER
   strictly-structured-block
[!$OMP END MASTER]
```

loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a MASTER construct is the current team. A master region binds to the innermost enclosing parallel region.

When the MASTER directive is specified, the other threads in the team skip the enclosed block (section) of code and continue execution. There is no implied barrier, either on entry to or exit from the master section.

The MASTER directive is deprecated; you should use the MASKED directive.

Example

The following example forces the master thread to execute the routines OUTPUT and INPUT:

```
!$OMP PARALLEL DEFAULT(SHARED)
      CALL WORK(X)
!$OMP MASTER
      CALL OUTPUT(X)
      CALL INPUT(Y)
!$OMP END MASTER
      CALL WORK(Y)
!$OMP END PARALLEL
```

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

MASTER TASKLOOP

OpenMP* Fortran Compiler Directive:
(Deprecated; replaced by MASKED TASKLOOP)
Creates a MASTER construct containing a TASKLOOP construct, with no Fortran statements in the MASTER construct that are not also in the TASKLOOP construct.
This feature is only available for ifx.

Syntax

```
!$OMP MASTER TASKLOOP [clause[[,] clause]... ]
   loop-nest
[!$OMP END MASTER TASKLOOP]
```

clause	Can be any of the clauses accepted by the MASTER or TASKLOOP directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a MASTER construct with a TASKLOOP construct nested inside of it. The semantics are identical to a TASKLOOP construct specified immediately after a MASTER construct.

All restrictions for MASTER and TASKLOOP constructs apply to this combined construct.

The MASTER TASKLOOP directive is deprecated; you should use the MASKED TASKLOOP directive.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
MASTER directive
TASKLOOP directive

To learn more about canonical form loops, see the OpenMP* specification.

MASTER TASKLOOP SIMD

OpenMP* Fortran Compiler Directive:
(Deprecated; replaced by MASKED TASKLOOP SIMD) Creates a MASTER construct containing a TASKLOOP SIMD construct, with no Fortran statements in the MASTER construct that are not also in the TASKLOOP SIMD construct. This feature is only available for ifx.

Syntax

```
!$OMP MASTER TASKLOOP SIMD [clause[[,] clause]... ]
   loop-nest
[!$OMP END MASTER TASKLOOP SIMD]
```

clause	Can be any of the clauses accepted by the MASTER or TASKLOOP SIMD directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a MASTER construct with a TASKLOOP SIMD construct nested inside of it. The semantics are identical to a TASKLOOP SIMD construct specified immediately after a MASTER construct; the only Fortran statements in the construct are inside the block.

All restrictions for MASTER and TASKLOOP SIMD constructs apply to this combined construct.

The MASTER TASKLOOP SIMD directive is deprecated; you should use the MASKED TASKLOOP SIMD directive.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
MASTER directive
TASKLOOP SIMD directive

To learn more about canonical form loops, see the OpenMP* specification.

MATMUL

Transformational Intrinsic Function (Generic):
Performs matrix multiplication of numeric or logical matrices.

Syntax

```
result = MATMUL (matrix_a,matrix_b)
```

matrix_a	(Input) Must be an array of rank one or two. It must be of numeric (integer, real, or complex) or logical type.
matrix_b	(Input) Must be an array of rank one or two. It must be of numeric type if *matrix_a* is of numeric type or logical type if *matrix_a* is logical type. At least one argument must be of rank two. The size of the first (or only) dimension of *matrix_b* must equal the size of the last (or only) dimension of *matrix_a*.

Results

The result is an array whose type depends on the data type of the arguments, according to the rules described in Data Type of Numeric Expressions. The rank and shape of the result depends on the rank and shapes of the arguments, as follows:

- If *matrix_a* has shape (n, m) and *matrix_b* has shape (m, k), the result is a rank-two array with shape (n, k).
- If *matrix_a* has shape (m) and *matrix_b* has shape (m, k), the result is a rank-one array with shape (k).
- If *matrix_a* has shape (n, m) and *matrix_b* has shape (m), the result is a rank-one array with shape (n).

If the arguments are of numeric type, element (i, j) of the result has the value SUM((row i of *matrix_a*) * (column j of *matrix_b*)). If the arguments are of logical type, element (i, j) of the result has the value ANY((row i of *matrix_a*) .AND. (column j of *matrix_b*)).

Example

A is matrix

```
 [ 2  3  4 ]
 [ 3  4  5 ],
```

B is matrix

```
 [ 2  3 ]
 [ 3  4 ]
 [ 4  5 ],
```

X is vector (1, 2), and Y is vector (1, 2, 3).

The result of MATMUL (A, B) is the matrix-matrix product AB with the value

```
 [ 29  38 ]
 [ 38  50 ].
```

The result of MATMUL (X, A) is the vector-matrix product XA with the value (8, 11, 14).

The result of MATMUL (A, Y) is the matrix-vector product AY with the value (20, 26).

The following shows another example:

```
INTEGER a(2,3), b(3,2), c(2), d(3), e(2,2), f(3), g(2)
a = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
!  a is   1 3 5
!         2 4 6
b = RESHAPE((/1, 2, 3, 4, 5, 6/), (/3, 2/))
!  b is   1 4
!         2 5
!         3 6
c = (/1, 2/)       ! c is [1 2]
d = (/1, 2, 3/)    ! d is [1 2 3]
```

```
e = MATMUL(a, b)     ! returns 22 49
                     !         28 64

f = MATMUL(c,a)    ! returns [5 11 17]
g = MATMUL(a,d)    ! returns [22 28]
WRITE(*,*) e, f, g
END
```

TRANSPOSE
PRODUCT

MAX

Elemental Intrinsic Function (Generic): *Returns the maximum value of the arguments.*

Syntax

`result = MAX (a1,a2[,a3]...)`

a1, a2, a3	(Input) All must have the same type (integer, real, or character) and kind parameters.

Results

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MAX0, AMAX1, DMAX1, QMAX1, IMAX0, JMAX0, and KMAX0, the result type is the same as the arguments. For MAX1, IMAX1, JMAX1, and KMAX1, the result type is integer. For AMAX0, AIMAX0, AJMAX0, and AKMAX0, the result type is real. The value of the result is that of the largest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

The Fortran standard does not define the behavior if one or more real arguments is a NaN and at least one argument is not a NaN. Depending on the order of the arguments, the result may be either the maximum non-NaN value or a NaN.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1)	INTEGER(1)
IMAX0	INTEGER(2)	INTEGER(2)
AIMAX0	INTEGER(2)	REAL(4)
MAX0 [2]	INTEGER(4)	INTEGER(4)
AMAX0 [3, 4]	INTEGER(4)	REAL(4)
KMAX0	INTEGER(8)	INTEGER(8)
AKMAX0	INTEGER(8)	REAL(4)
IMAX1	REAL(4)	INTEGER(2)
MAX1 [4, 5, 6]	REAL(4)	INTEGER(4)
KMAX1	REAL(4)	INTEGER(8)
AMAX1 [7]	REAL(4)	REAL(4)

Specific Name [1]	Argument Type	Result Type
DMAX1	REAL(8)	REAL(8)
QMAX1	REAL(16)	REAL(16)

[1]These specific functions cannot be passed as actual arguments.

[2]Or JMAX0.

[3]Or AJMAX0.AMAX0 is the same as REAL (MAX).

[4]In Standard Fortran, AMAX0 and MAX1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

[5]Or JMAX1. MAX1 is the same as INT(MAX).

[6]The setting of compiler options specifying integer size can affect MAX1.

[7]The setting of compiler options specifying real size can affect AMAX1.

Example

MAX (2.0, -8.0, 6.0) has the value 6.0.

MAX (14, 32, -50) has the value 32.

The following shows another example:

```
INTEGER m1, m2
REAL r1, r2
m1 = MAX(5, 6, 7)           ! returns 7
m2 = MAX1(5.7, 3.2, -8.3)   ! returns 5
r1 = AMAX0(5, 6, 7)         ! returns 7.0
r2 = AMAX1(6.4, -12.2, 4.9) ! returns 6.4
```

MIN

MAXEXPONENT

Inquiry Intrinsic Function (Generic): *Returns the maximum exponent in the model representing the same type and kind parameters as the argument.*

Syntax

```
result = MAXEXPONENT (x)
```

x (Input) Must be of type real; it can be scalar or array valued.

Results

The result is a scalar of type default integer. The result has the value e_{max}, as defined in Model for Real Data.

Example

```
REAL(4) x
INTEGER i
i = MAXEXPONENT(x)    ! returns 128.
```

See Also

MINEXPONENT

MAXLOC

Transformational Intrinsic Function (Generic):
Returns the location of the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

`result = MAXLOC (array, dim [, mask, kind, back])`

`result = MAXLOC (array [, mask, kind, back])`

array	(Input) Must be an array of type integer, real, or character. Note that the Fortran standard does not define the behavior of this function if *array* is a real type and one or more elements is a Nan.
dim	(Input) Must be a scalar integer with a value in the range 1 to *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be a logical array that is conformable with *array*.
kind	(Input; optional) Must be a scalar integer constant expression.
back	(Input; optional) Must be a scalar of type logical.

Results

The result is an array of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if *dim* is not specified:

- The array result has rank one and a size equal to the rank of *array*.
- If MAXLOC(*array*) is specified, the elements in the array result form the subscript of the location of the element with the maximum value in *array*.

  The *i*th subscript returned lies in the range 1 to e_i, where e_i is the extent of the *i*th dimension of *array*.
- If MAXLOC(*array*, MASK= *mask*) is specified, the elements in the array result form the subscript of the location of the element with the maximum value corresponding to the condition specified by *mask*.

The following rules apply if *dim* is specified:

- The array result has a rank that is one less than *array*, and shape (d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n), where (d_1, d_2,...d_n) is the shape of *array*.
- If *array* has rank one, MAXLOC(*array*, *dim* [, *mask*]) is a scalar and has a value equal to the first element of MAXLOC(*array* [, MASK = *mask*]). Otherwise, the value of element (s_1, s_2,...s_{dim-1}, s_{dim+1},...s_n) of MAXLOC(*array*, *dim* [, *mask*]) is equal to MAXLOC(*array*(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n) [, MASK = *mask*(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n)]).

If only one element has the maximum value, that element's subscripts are returned. Otherwise, if more than one element has the maximum value and *back* is absent or present with the value .FALSE., the element whose subscripts are returned is the first such element, taken in array element order. If *back* is present with the value .TRUE., the element whose subscripts are returned is the last such element, taken in array element order.

If *array* has size zero, or every element of *mask* has the value .FALSE., the value of the result is controlled by compiler option `assume [no]old_maxminloc`, which can set the value of the result to either 1 or 0.

If *array* is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

Example

The value of MAXLOC((/3, 7, 4, 7/)) is (2), which is the subscript of the location of the first occurrence of the maximum value in the rank-one array.

A is the array

```
[  4    0    4    2 ]
[  3    1   -2    6 ]
[ -1   -4    5    5 ].
```

MAXLOC (A, MASK=A .LT. 5) has the value (1, 1) because these are the subscripts of the location of the first maximum value (4) that is less than 5.

MAXLOC (A, DIM=1) has the value (1, 2, 3, 2). 1 is the subscript of the location of the first maximum value (4) in column 1; 2 is the subscript of the location of the first maximum value (1) in column 2; and so forth.

MAXLOC (A, DIM=2) has the value (1, 4, 3). 1 is the subscript of the location of the first maximum value in row 1; 4 is the subscript of the location of the first maximum value in row 2; and so forth.

MAXLOC (A, DIM=2, BACK=.TRUE.) has the value (3, 4, 4). 3 is the subscript of the location of the last maximum value in row 1; 4 is the subscript of the location of the last maximum value in row 2; and so forth.

The following shows another example:

```
INTEGER i, maxl(1), max
INTEGER array(3, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/7, 9, -1, -2, 5, 0, 3, 6, 9/),     &
                (/3, 3/))
! array is  7 -2 3
!           9  5 6
!          -1  0 9
i = SIZE(SHAPE(array))   ! Get number of dimensions
                         ! in array
ALLOCATE ( AR1(i))       ! Allocate AR1 to number
                         ! of dimensions in array
AR1 = MAXLOC (array, MASK = array .LT. 7) ! Get
                         ! the location (subscripts) of
                         ! largest element less than 7
                         ! in array
!
! MASK = array .LT. 7 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is less than 7,
! and .FALSE. if it is not. This mask causes MAXLOC to
! return the index of the element in array with the
! greatest value less than 7.
!
! array is  7 -2 3 and MASK=array .LT. 7 is  F T T
!           9  5 6                           F T T
!          -1  0 9                           T T F
! and AR1 = MAXLOC(array, MASK = array .LT. 7) returns
```

```
! (2, 3), the location of the element with value 6

maxl = MAXLOC((/1, 4, 3, 4/))    ! returns 2, the first
                                 ! occurrence of maximum
END
```

FINDLOC

MAXVAL

Transformational Intrinsic Function (Generic):
Returns the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

`result = MAXVAL (array [, mask])`

`result = MAXVAL (array, dim [, mask])`

array	(Input) Must be an array of type integer, real, or character. Note that the Fortran standard does not define the behavior of this function if *array* is a real type and one or more elements is a Nan.
dim	(Input) Must be a scalar integer expression with a value in the range 1 to n, where *n* is the rank of *array*.
mask	(Input; optional) Must be a logical array that is conformable with *array*.

Results

The result is an array or a scalar of the same data type as *array*.

The result is a scalar if *dim* is not specified or *array* has rank one.

The following rules apply if *dim* is not specified:

- If MAXVAL(*array*) is specified, the result has a value equal to the maximum value of all the elements in *array*.
- If MAXVAL(*array*, MASK= *mask*) is specified, the result has a value equal to the maximum value of the elements in *array* corresponding to the condition specified by *mask*.

The following rules apply if *dim* is specified:

- An array result has a rank that is one less than *array*, and shape (d_1, d_2,...,d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *array*.
- If *array* has rank one, MAXVAL(*array*, *dim*[, *mask*]) has a value equal to that of MAXVAL(*array*[,MASK = *mask*]). Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n) of MAXVAL(*array*, *dim*, [, *mask*]) is equal to MAXVAL(*array*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) [,MASK = *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)]).

If *array* has size zero or if there are no true elements in *mask*, the result (if *dim* is omitted), or each element in the result array (if *dim* is specified), has the value of the negative number of the largest magnitude supported by the processor for numbers of the type and kind parameters of *array*.

If *array* is of type character, the comparison is done using the ASCII collating sequence.

Example

The value of MAXVAL ((/2, 3, 4/)) is 4 because that is the maximum value in the rank-one array.

MAXVAL (B, MASK=B .LT. 0.0) finds the maximum value of the negative elements of B.

C is the array

```
 [ 2  3  4 ]
 [ 5  6  7 ].
```

MAXVAL (C, DIM=1) has the value (5, 6, 7). 5 is the maximum value in column 1; 6 is the maximum value in column 2; and so forth.

MAXVAL (C, DIM=2) has the value (4, 7). 4 is the maximum value in row 1 and 7 is the maximum value in row 2.

The following shows another example:

```
INTEGER array(2,3), i(2), max
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/),(/2, 3/))
! array is   1 5 3
!            4 2 6
i = SHAPE(array)      ! i = [2 3]
ALLOCATE (AR1(i(2)))  ! dimension AR1 to the number of
                      ! elements in dimension 2
                      ! (a column) of array
ALLOCATE (AR2(i(1)))  ! dimension AR2 to the number of
                      ! elements in dimension 1
                      ! (a row) of array
max = MAXVAL(array, MASK = array .LT. 4) ! returns 3
AR1 = MAXVAL(array, DIM = 1)  ! returns [ 4 5 6 ]
AR2 = MAXVAL(array, DIM = 2)  ! returns [ 5 6 ]
END
```

MAXLOC
MINVAL
MINLOC

MCLOCK

Inquiry Intrinsic Function (Specific): *Returns time accounting for a program.*

Syntax

```
result = MCLOCK( )
```

Results

The result type is INTEGER(4). The result is the sum (in units of milliseconds) of the current process's user time and the user and system time of all its child processes.

MERGE

Elemental Intrinsic Function (Generic): *Selects between two values or between corresponding elements in two arrays, according to the condition specified by a logical mask.*

Syntax

result = MERGE (*tsource*,*fsource*,*mask*)

tsource	(Input) May be of any data type.
fsource	(Input) Must be of the same type and type parameters as *tsource*.
mask	(Input) Must be of type logical.

Results

The result type and kind are the same as *tsource*. The value of *mask* determines whether the result value is taken from *tsource* (if *mask* is true) or *fsource* (if *mask* is false).

Example

For MERGE (1.0, 0.0, R < 0), R = -3 has the value 1.0, and R = 7 has the value 0.0.

TSOURCE is the array

```
  [ 1  3  5 ]
  [ 2  4  6 ],
```

FSOURCE is the array

```
  [ 8  9  0 ]
  [ 1  2  3 ],
```

and MASK is the array

```
  [ F  T  T]
  [ T  T  F].
```

MERGE (TSOURCE, FSOURCE, MASK) produces the result:

```
  [ 8  3  5 ]
  [ 2  4  3 ].
```

The following shows another example:

```
INTEGER tsource(2, 3), fsource(2, 3), AR1 (2, 3)
LOGICAL mask(2, 3)
tsource = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2, 3/))
fsource = RESHAPE((/7, 0, 8, -1, 9, -2/), (/2, 3/))
mask = RESHAPE((/.TRUE., .FALSE., .FALSE., .TRUE.,         &
                .TRUE., .FALSE./), (/2,3/))
! tsource is  1 2 3 , fsource is  7  8  9 , mask is  T F T
!             4 5 6               0 -1 -2            F T F

AR1 = MERGE(tsource, fsource, mask) ! returns  1 8  3
                                    !          0 5 -2
END
```

MERGE_BITS

Elemental Intrinsic Function (Generic): *Merges bits by using a mask.*

Syntax

result = MERGE_BITS (*i*,*j*,*mask*)

i	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
j	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.
mask	(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer they must have the same kind type parameter. They cannot both be binary, octal, or hexadecimal literal constants.

If *mask* is of type integer, it must have the same kind type parameter as each other argument of type integer.

Results

The result type and kind are the same as *i* if *i* is of type integer; otherwise, the result type and kind are the same as *j*.

If any argument is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to the type and kind parameter of the result. The result has the value of IOR (IAND (*i*, *mask*), IAND (*j*, NOT (*mask*))).

Example

MERGE_BITS (13, 18, 22) has the value 4.

MERGEABLE Clause

Parallel Directive Clause: *Specifies that the implementation may generate a merged task.*

Syntax

```
MERGEABLE
```

When the generated task is an undeferred task or an included task, it specifies that the implementation may instead generate a merged task.

When the MERGEABLE clause is present on a TASKLOOP construct, each generated task is a mergeable task.

MESSAGE

General Compiler Directive: *Specifies a character string to be sent to the standard output device during the first compiler pass; this aids debugging.*

Syntax

```
!DIR$ MESSAGE:string
```

string	Is a character constant specifying a message.

Example

```
!DIR$ MESSAGE:'Compiling Sound Speed Equations'
```

See Also

General Compiler Directives

Syntax Rules for Compiler Directives

METADIRECTIVE

OpenMP* Fortran Compiler Directive: *Specifies variant OpenMP* directives, one of which may conditionally replace the metadirective based on the OpenMP context enclosing the metadirective. This feature is only available for ifx.*

Syntax

```
!$OMP METADIRECTIVE [clause [[,] clause]...]
```

-or-

```
!$OMP BEGIN METADIRECTIVE [clause [[,] clause]...]
   statement(s)
!$OMP END METADIRECTIVE
```

clause

Is one of the following:

- DEFAULT ([*directive-variant*])

  This clause has been deprecated and renamed OTHERWISE.
- OTHERWISE ([*directive-variant*])

  Identifies a default *directive-variant* if the context does not match one of the WHEN clauses. Only one OTHERWISE clause can be specified. If it appears, it must be the last clause specified. If it does not appear, it is as if OTHERWISE (NOTHING) appears.
- WHEN (*context-selector-spec* :[*directive-variant*])

  Specifies a *directive-variant* to replace the METADIRECTIVE when the OpenMP context matches the *context-selector* specified. Expressions in the *context-selector* of a WHEN clause are evaluated if no prior WHEN clause in the directive specifies a compatible or matching OpenMP context. The number of times an expression can be evaluated is implementation defined.

directive-variant

Is an OpenMP directive (with no sentinel). It is a candidate for replacing the metadirective in which it appears. If *directive-variant* does not appear, it is as if a NOTHING directive was specified. A *directive-variant* cannot be a metadirective.

context-selector-spec

Is an OpenMP context-selector. Currently, only USER context selectors whose CONDITION is a logical constant expression are allowed. The *context-selector-spec* cannot specify properties of a SIMD directive.

statement(s)

Is one or more valid Fortran statements.

A METADIRECTIVE specifies one or more candidate OpenMP directives (*directive-variant* s) that may conditionally replace the METADIRECTIVE. Selection of a replacement candidate depends on the OpenMP context that encloses the METADIRECTIVE.

The order of clauses is significant. Replacement candidates are ordered according to these rules, in decreasing precedence:

- A *directive-variant* candidate has higher precedence than another candidate if the score of the context-selector of its corresponding WHEN clause is higher.
- Explicitly specified candidates have precedence over implicitly specified candidates.
- A *directive-variant* candidate that appears in a WHEN clause specified lexically before another in a METADIRECTIVE has higher precedence.

The first replacement candidate in the ordered list of candidates whose corresponding WHEN clause specifies a compatible context-selector replaces the METADIRECTIVE. See Score and Match OpenMP Context Selectors.

Replacement of the METADIRECTIVE with the selected *directive-variant* must result in a conforming OpenMP program.

Example

In the program below, _OFFLOADING is a preprocessor macro.

```
PROGRAM offloading_success
USE omp_lib
IMPLICIT NONE
INTEGER :: errors
LOGICAL :: is_host

is_host = .FALSE.

!$omp BEGIN METADIRECTIVE WHEN(USER={CONDITION(_OFFLOADING)}: PARALLEL DO SIMD) &
             WHEN(USER={CONDITION(_OFFLOADING)}: TARGET MAP (FROM: is_host)

   isHost = omp_is_initial_device ()

!$omp END METADIRECTIVE

! check if target region executed on the device
IF (is_host) THEN
   errors = 1
   PRINT *, "Failed - target region executed on the host"
ELSE
   errors = 0
   PRINT *, "Passed"
END IF

IF( errors .NE. 0 ) STOP 1

END PROGRAM offloading_success
```

If the above program is preprocessed with _OFFLOADING defined to be .TRUE., the METADIRECTIVE construct will be replaced with the following:

```
!$omp TARGET MAP (FROM:is_host)
is_host = omp_is_initial_device ()
!$omp END TARGET
```

The code following the METADIRECTIVE determines if the METADIRECTIVE resulted in a TARGET region. If so, it tests to determine whether the TARGET region successfully offloaded to the device.

OpenMP Contexts
OpenMP Context Selectors
Syntax Rules for Compiler Directives

MIN

Elemental Intrinsic Function (Generic): *Returns the minimum value of the arguments.*

Syntax

`result = MIN (a1,a2[,a3...])`

a1, *a2*, *a3*	(Input) All must have the same type (integer, real, or character) and kind parameters.

Results

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MIN0, AMIN1, DMIN1, QMIN1, IMIN0, JMIN0, and KMIN0, the result type is the same as the arguments. For MIN1, IMIN1, JMIN1, and KMIN1, the result type is integer. For AMIN0, AIMIN0, AJMIN0, and AKMIN0, the result type is real. The value of the result is that of the smallest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

The Fortran standard does not define the behavior if one or more real arguments is a NaN and at least one argument is not a NaN. Depending on the order of the arguments, the result may be either the minimum non-NaN value or a NaN.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1)	INTEGER(1)
IMIN0	INTEGER(2)	INTEGER(2)
AIMIN0	INTEGER(2)	REAL(4)
MIN0 [2]	INTEGER(4)	INTEGER(4)
AMIN0 [3, 4]	INTEGER(4)	REAL(4)
KMIN0	INTEGER(8)	INTEGER(8)
AKMIN0	INTEGER(8)	REAL(4)
IMIN1	REAL(4)	INTEGER(2)
MIN1 [4, 5, 6]	REAL(4)	INTEGER(4)
KMIN1	REAL(4)	INTEGER(8)
AMIN1 [7]	REAL(4)	REAL(4)
DMIN1	REAL(8)	REAL(8)
QMIN1	REAL(16)	REAL(16)

[1]These specific functions cannot be passed as actual arguments.

[2]Or JMIN0.

[3]Or AJMIN0.AMIN0 is the same as REAL (MIN).

[4]In Standard Fortran, AMIN0 and MIN1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

[5]Or JMIN1.MIN1 is the same as INT (MIN).

[6]The setting of compiler options specifying integer size can affect MIN1.

[7]The setting of compiler options specifying real size can affect AMIN1.

Example

MIN (2.0, -8.0, 6.0) has the value -8.0.

MIN (14, 32, -50) has the value -50.

The following shows another example:

```
INTEGER m1, m2
REAL r1, r2
m1 = MIN (5, 6, 7)            ! returns 5
m2 = MIN1 (-5.7, 1.23, -3.8) ! returns -5
r1 = AMIN0 (-5, -6, -7)       ! returns -7.0
r2 = AMIN1(-5.7, 1.23, -3.8) ! returns -5.7
```

IEEE_MIN_NUM
MINLOC
MINVAL
MAX

MINEXPONENT

Inquiry Intrinsic Function (Generic): *Returns the minimum exponent in the model representing the same type and kind parameters as the argument.*

Syntax

`result = MINEXPONENT (x)`

x	(Input) must be of type real; it can be scalar or array valued.

Results

The result is a scalar of type default integer. The result has the value e_{min}, as defined in Model for Real Data.

Example

If X is of type REAL(4), MINEXPONENT (X) has the value -125.

The following shows another example:

```
REAL(8) r1  ! DOUBLE PRECISION REAL
INTEGER i
i = MINEXPONENT (r1) ! returns - 1021.
```

See Also

MAXEXPONENT

MINLOC

Transformational Intrinsic Function (Generic): *Returns the location of the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.*

Syntax

`result = MINLOC (array, dim [, mask, kind, back])`

`result = MINLOC (array [, mask, kind, back])`

array	(Input) Must be an array of type integer, real, or character. Note that the Fortran standard does not define the behavior of this function if *array* is a real type and one or more elements is a Nan.

dim	(Input) Must be a scalar integer with a value in the range 1 to *n*, where *n* is the rank of *array*.
mask	(Input; optional) Must be a logical array that is conformable with *array*.
kind	(Input; optional) Must be a scalar integer constant expression.
back	(Input; optional) Must be a scalar of type logical.

Results

The result is an array of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if *dim* is not specified:

- The array result has rank one and a size equal to the rank of *array*.
- If MINLOC(*array*) is specified, the elements in the array result form the subscript of the location of the element with the minimum value in *array*.

  The *i*th subscript returned lies in the range 1 to e_i, where e_i is the extent of the *i*th dimension of *array*.
- If MINLOC(*array*, MASK= *mask*) is specified, the elements in the array result form the subscript of the location of the element with the minimum value corresponding to the condition specified by *mask*.

The following rules apply if *dim* is specified:

- The array result has a rank that is one less than *array*, and shape (d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n), where (d_1, d_2,...d_n) is the shape of *array*.
- If *array* has rank one, MINLOC(*array*, *dim* [, *mask*]) is a scalar and has a value equal to the first element of MINLOC(*array* [,MASK = *mask*]). Otherwise, the value of element (s_1, s_2,...s_{dim-1}, s_{dim+1},...s_n) of MINLOC(*array*, *dim* [, *mask*]) is equal to MINLOC(*array*(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n) [, MASK = *mask*(s_1, s_2,...s_{dim-1}, :, s_{dim+1},...s_n)]).

If only one element has the minimum value, that element's subscripts are returned. Otherwise, if more than one element has the minimum value and *back* is absent or present with the value .FALSE., the element whose subscripts are returned is the first such element, taken in array element order. If *back* is present with the value .TRUE., the element whose subscripts are returned is the last such element, taken in array element order.

If *array* has size zero, or every element of *mask* has the value .FALSE., the value of the result is controlled by compiler option `assume [no]old_maxminloc`, which can set the value of the result to either 1 or 0.

If *array* is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

Example

The value of MINLOC ((/3, 1, 4, 1/)) is (2), which is the subscript of the location of the first occurrence of the minimum value in the rank-one array.

A is the array

```
[  4    0   0    2 ]
[  3   -6   -2    6 ]
[ -1   -4    5   -4 ].
```

MINLOC (A, MASK=A .GT. -5) has the value (3, 2) because these are the subscripts of the location of the first minimum value (-4) that is greater than -5.

MINLOC (A, DIM=1) has the value (3, 2, 2, 3). 3 is the subscript of the location of the first minimum value (-1) in column 1; 3 is the subscript of the location of the first minimum value (-6) in column 2; and so forth.

MINLOC (A, DIM=2) has the value (2, 2, 2). 2 is the subscript of the location of the first minimum value (0) in row 1; 2 is the subscript of the location of the first minimum value (-6) in row 2; and so forth.

MINLOC (A, DIM=2, BACK=.TRUE.) has the value (3, 2, 4). 3 is the subscript of the location of the last minimum value (0) in row 1; 2 is the subscript of the location of the last minimum value (-6) in row 2; and so forth.

The following shows another example:

```
INTEGER i, minl(1)
INTEGER array(2, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/-7, 1, -2, -9, 5, 0/),(/2, 3/))
!   array is   -7 -2 5
!               1 -9 0
i = SIZE(SHAPE(array))  ! Get the number of dimensions
                        !   in array
ALLOCATE (AR1 (i))      ! Allocate AR1 to number
                        !   of dimensions in array
AR1 = MINLOC (array, MASK = array .GT. -5)   ! Get the
                        !   location (subscripts) of
                        !   smallest element greater
                        !   than -5 in array

!
! MASK = array .GT. -5 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is greater than
! -5, and .FALSE. if it is not. This mask causes MINLOC
! to return the index of the element in array with the
! smallest value greater than -5.
!
!array is  -7 -2 5 and MASK= array .GT. -5 is  F T T
!           1 -9 0                              T F T
! and AR1 = MINLOC(array, MASK = array .GT. -5) returns
! (1, 2), the location of the element with value -2

minl = MINLOC((/-7,2,-7,5/))   ! returns 1, first
                               ! occurrence of minimum
END
```

MAXLOC
MINVAL
MAXVAL
FINDLOC

MINVAL

Transformational Intrinsic Function (Generic):
Returns the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

```
result = MINVAL (array [, mask])
result = MINVAL (array, dim [, mask])
```

array	(Input) Must be an array of type integer, real, or character. Note that the Fortran standard does not define the behavior of this function if *array* is a real type and one or more elements is a Nan.
dim	(Input) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*.
mask	(Input; optional) Must be a logical array that is conformable with *array*.

Results

The result is an array or a scalar of the same data type as *array*.

The result is a scalar if *dim* is omitted or *array* has rank one.

The following rules apply if *dim* is not specified:

- If MINVAL(*array*) is specified, the result has a value equal to the minimum value of all the elements in *array*.
- If MINVAL(*array*, MASK= *mask*) is specified, the result has a value equal to the minimum value of the elements in *array* corresponding to the condition specified by *mask*.

The following rules apply if *dim* is specified:

- An array result has a rank that is one less than *array*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *array*.
- If *array* has rank one, MINVAL(*array*, *dim*[, *mask*]) has a value equal to that of MINVAL(*array*[,MASK = *mask*]). Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n) of MINVAL(*array*, *dim*, [, *mask*]) is equal to MINVAL(*array*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) [,MASK = *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)]).

If *array* has size zero or if there are no true elements in *mask*, the result (if *dim* is omitted), or each element in the result array (if *dim* is specified), has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind parameters of *array*.

If *array* is of type character, the comparison is done using the ASCII collating sequence.

Example

The value of MINVAL ((/2, 3, 4/)) is 2 because that is the minimum value in the rank-one array.

The value of MINVAL (B, MASK=B .GT. 0.0) finds the minimum value of the positive elements of B.

C is the array

```
  [ 2  3  4 ]
  [ 5  6  7 ].
```

MINVAL (C, DIM=1) has the value (2, 3, 4). 2 is the minimum value in column 1; 3 is the minimum value in column 2; and so forth.

MINVAL (C, DIM=2) has the value (2, 5). 2 is the minimum value in row 1 and 5 is the minimum value in row 2.

The following shows another example:

```
INTEGER array(2, 3), i(2), minv
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
!    array is    1 5 3
!                4 2 6
i = SHAPE(array)     ! i = [2 3]
ALLOCATE(AR1(i(2))) ! dimension AR1 to number of
                    ! elements in dimension 2
                    ! (a column) of array.
ALLOCATE(AR2(i(1))) ! dimension AR2 to number of
                    ! elements in dimension 1
                    ! (a row) of array
minv = MINVAL(array, MASK = array .GT. 4) ! returns 5
AR1 = MINVAL(array, DIM = 1)    ! returns [ 1 2 3 ]
AR2 = MINVAL(array, DIM = 2)    ! returns [ 1 2 ]
END
```

MAXLOC

MM_PREFETCH

Intrinsic Subroutine (Generic): *Prefetches data from the specified address on one memory cache line. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

CALL MM_PREFETCH (*address*[,*hint*] [,*fault*] [,*exclusive*])

address (Input) Is the name of a scalar or array; it can be of any type or rank. It specifies the address of the data on the cache line to prefetch.

hint (Input; optional) Is an optional default integer constant with one of the following values:

Value	Prefetch Constant	Description
0	FOR_K_PREFETCH_T0	Prefetches into the L1 cache (and the L2 and the L3 cache). Use this for integer data.
1	FOR_K_PREFETCH_T1	Prefetches into the L2 cache (and the L3 cache); floating-point data is used from the L2 cache, not the L1 cache. Use this for real data.

Value	Prefetch Constant	Description
2	FOR_K_PREFETCH_T2	Prefetches into the L2 cache (and the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line frequently.
3	FOR_K_PREFETCH_NTA	Prefetches into the L2 cache (but *not* the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line.

The preceding constants are defined in file `fordef.for` on Windows* systems and file `fordef.f` on Linux* systems.

If *hint* is omitted, 0 is assumed.

fault

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, page faults are allowed to occur, if necessary; if .FALSE. is specified, page faults are not allowed to occur. If *fault* is omitted, .FALSE. is assumed. This argument is currently ignored.

exclusive

(Input; optional) Is an optional default logical constant. If.TRUE. is specified, you get exclusive ownership of the cache line because you intend to assign to it; if .FALSE. is specified, there is no exclusive ownership. If *exclusive* is omitted, .FALSE.is assumed. This argument is currently ignored.

Example

```
subroutine spread_lf (a, b)
PARAMETER (n = 1025)

real*8 a(n,n), b(n,n), c(n)
do j = 1,n
  do i = 1,100
    a(i, j) = b(i-1, j) + b(i+1, j)
    call mm_prefetch (a(i+20, j), 1)
    call mm_prefetch (b(i+21, j), 1)
  enddo
enddo

print *, a(2, 567)

stop
end
```

MOD

Elemental Intrinsic Function (Generic): *Returns the remainder when the first argument is divided by the second argument.*

Syntax

```
result = MOD (a, p)
```

a	(Input) Must be of type integer or real.
p	(Input)Must have the same type and kind parameters as *a*. It must not have a value of zero.

Results

The result type and kind are the same as *a*. If *p* is not equal to zero, the value of the result is *a* - INT(*a*/ *p*) * *p*. If *p* is equal to zero, the result is undefined.

Specific Name	Argument Type	Result Type
BMOD	INTEGER(1)	INTEGER(1)
IMOD[1]	INTEGER(2)	INTEGER(2)
MOD [2]	INTEGER(4)	INTEGER(4)
KMOD	INTEGER(8)	INTEGER(8)
AMOD [3]	REAL(4)	REAL(4)
DMOD [3,4]	REAL(8)	REAL(8)
QMOD	REAL(16)	REAL(16)

[1] Or HMOD.

[2] Or JMOD.

[3] The setting of compiler options specifying real size can affect AMOD and DMOD.

[4] The setting of compiler options specifying double size can affect DMOD.

Example

MOD (7, 3) has the value 1.

MOD (9, -6) has the value 3.

MOD (-9, 6) has the value -3.

The following shows more examples:

```
INTEGER I
REAL R
R = MOD(9.0, 2.0)  ! returns 1.0
I = MOD(18, 5)     ! returns 3
I = MOD(-18, 5)    ! returns -3
I = MOD( 8, 5)     ! returns 3
I = MOD(-8, 5)     ! returns -3
I = MOD( 8,-5)     ! returns 3
I = MOD(-8,-5)     ! returns -3
```

MODULO

MODULE

Statement: *Marks the beginning of a module program unit, which contains specifications and definitions that can be used by one or more program units.*

Syntax

```
MODULE name
   [specification-part]
[CONTAINS
   [module-subprogram
   [module-subprogram]...] ]
END[ MODULE [name]]
```

name	Is the name of the module.
specification-part	Is one or more specification statements, except for the following: • ENTRY • FORMAT • AUTOMATIC (or its equivalent attribute) • INTENT (or its equivalent attribute) • OPTIONAL (or its equivalent attribute) • Statement functions An automatic object must not appear in a specification statement.
module-subprogram	Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE. A module subprogram can contain internal procedures.

Description

If a name follows the END statement, it must be the same as the name specified in the MODULE statement.

The module name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A module is host to any module procedures it contains, and entities in the module are accessible to the module procedures through host association.

A module must not reference itself (either directly or indirectly).

You can use the PRIVATE attribute to restrict access to procedures or variables within a module.

Although ENTRY statements, FORMAT statements, and statement functions are not allowed in the specification part of a module, they are allowed in the specification part of a module subprogram.

The following rules also apply to modules:

- The specification part of a module must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.

- A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the *specification-part* of a module includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Any executable statements in a module can only be specified in a module subprogram.

A module can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.

Example

The following example shows a simple module that can be used to provide global data:

```
MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5)
END MODULE MOD_A
...
SUBROUTINE SUB_Z
  USE MOD_A               ! Makes scalar variables B and C, and array
  ...                     !   E available to this subroutine
END SUBROUTINE SUB_Z
```

The following example shows a module procedure:

```
MODULE RESULTS
...
CONTAINS
  FUNCTION MOD_RESULTS(X,Y)  ! A module procedure
  ...
  END FUNCTION MOD_RESULTS
END MODULE RESULTS
```

The following example shows a module containing a derived type:

```
MODULE EMPLOYEE_DATA
  TYPE EMPLOYEE
    INTEGER ID
    CHARACTER(LEN=40) NAME
  END TYPE EMPLOYEE
END MODULE
```

The following example shows a module containing an interface block:

```
MODULE ARRAY_CALCULATOR
  INTERFACE
    FUNCTION CALC_AVERAGE(D)
      REAL :: CALC_AVERAGE
      REAL, INTENT(IN) :: D(:)
    END FUNCTION
  END INTERFACE
END MODULE ARRAY_CALCULATOR
```

The following example shows a derived-type definition that is public with components that are private:

```
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
```

```
    INTEGER C, D
  END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

This design allows you to change components of a type without affecting other program units that use the module.

If a derived type is needed in more than one program unit, the definition should be placed in a module and accessed by a USE statement whenever it is needed, as follows:

```
MODULE STUDENTS
  TYPE STUDENT_RECORD
  ...
  END TYPE
CONTAINS
  SUBROUTINE COURSE_GRADE(...)
  TYPE(STUDENT_RECORD) NAME
  ...
  END SUBROUTINE
END MODULE STUDENTS
...

PROGRAM SENIOR_CLASS
  USE STUDENTS
  TYPE(STUDENT_RECORD) ID
  ...
END PROGRAM
```

Program SENIOR_CLASS has access to type STUDENT_RECORD, because it uses module STUDENTS. Module procedure COURSE_GRADE also has access to type STUDENT_RECORD, because the derived-type definition appears in its host.

MODULE PROCEDURE

Statement: *Identifies module procedures in an interface block that specifies a generic name.*

Example

```
!A program that changes non-default integers and reals
! into default integers and reals
   PROGRAM CHANGE_KIND
   USE Module1
   integer(2) in
   integer indef
   indef = DEFAULT(in)
   END PROGRAM

! procedures sub1 and sub2 defined as follows:
   MODULE Module1
    INTERFACE DEFAULT
      MODULE PROCEDURE Sub1, Sub2
    END INTERFACE
    CONTAINS
      FUNCTION Sub1(y)
        REAL(8) y
        sub1 = REAL(y)
      END FUNCTION
      FUNCTION Sub2(z)
        INTEGER Sub2
        INTEGER(2) z
        sub2 = INT(z)
      END FUNCTION
    END MODULE
```

Separate Module Procedures

MODULO

Elemental Intrinsic Function (Generic): *Returns the modulo of the arguments.*

Syntax

```
result = MODULO (a,p)
```

a	(Input) Must be of type integer or real.
p	(Input) Must have the same type and kind parameters as *a*. It must not have a value of zero.

Results

The result type is the same *a*. The result value depends on the type of *a*, as follows:

- If *a* is of type integer and *p* is not equal to zero, the value of the result is *a* - FLOOR(REAL(*a*) / REAL(*p*)) * *p*, that is, the *result* has a value such that *a* = *q* * *p* + *result* where *q* is an integer. The following also applies:
  - If *p* > 0, then 0 <= *result* < *p*
  - If *p* < 0, then *p* < *result* <= 0
- If *a* is of type real and *p* is not equal to zero, the value of the result is *a* - FLOOR(*a*/ *p*) * *p*.

If *p* is equal to zero (regardless of the type of *a*), the result is undefined.

Example

MODULO (7, 3) has the value 1.

MODULO (9, -6) has the value -3.

MODULO (-9, 6) has the value 3.

The following shows more examples:

```
INTEGER I
REAL R
I= MODULO(8, 5)         ! returns 3          Note: q=1
I= MODULO(-8, 5)        ! returns 2          Note: q=-2
I= MODULO(8, -5)        ! returns -2         Note: q=-2
I= MODULO(-8,-5)        ! returns -3         Note: q=1
R= MODULO(7.285, 2.35)  ! returns 0.2350001  Note: q=3
R= MODULO(7.285, -2.35) ! returns -2.115     Note: q=-4
```

MOD

MOVE_ALLOC

Intrinsic Subroutine (Generic): *Moves an allocation from one allocatable object to another. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

```
CALL MOVE_ALLOC (from,to [, stat, errmsg])
```

from	(Input; output) Can be of any type, type parameters, corank, and rank; it must be allocatable.

to	(Output) Must be type compatible with `from` and have the same rank and corank; it must be allocatable. It must be polymorphic if `from` is polymorphic. Each nondeferred type parameter of the declared type of `to` must have the same value as the corresponding type parameter of the declared type of `from`. For more information about type compatibility, see the description in CLASS.
stat	(Output, optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least 4 (KIND=2) or greater.
errmsg	(Input; output; optional) Must be a non-coindexed default character variable.

When the execution of MOVE_ALLOC is successful, or if STAT is assigned the value STAT_FAILED_IMAGE, the following occurs:

- If `to` is currently allocated, it is deallocated.
- If `from` is allocated, `to` becomes allocated with the same type, type parameters, array bounds, and values as from.
- `from` is deallocated.

If `to` has the TARGET attribute, any pointer associated with `from` at the time of the call to MOVE_ALLOC becomes correspondingly associated with `to`. If `to` does not have the TARGET attribute, the pointer association status of any pointer associated with `from` on entry becomes undefined.

During execution of MOVE_ALLOC, the internal descriptor contents are copied from `from` to `to`, so that the storage pointed to by `to` is the storage that `from` used to point to.

Typically, MOVE_ALLOC is used to provide an efficient way to reallocate a variable to a larger size without copying the data twice.

A reference to MOVE_ALLOC that has a coarray from argument has an implicit synchronization of all active images of the current team. No image proceeds until all active images of the current team have completed execution of the reference. If the current team contains any images that have stopped or failed, an error condition occurs.

If the procedure reference is successful, *stat* becomes defined with the value zero.

If an error condition occurs and *stat* is not specified, error termination is initiated. If *stat* is present and the current team contains an image that has stopped, *stat* becomes defined with the value STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. Otherwise, if *stat* is present, the current team contains a failed image, and no other error condition occurs, *stat* becomes defined with the value STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. Otherwise, *stat* becomes defined with a positive integer value different from STAT_STOPPED_IMAGE and STAT_FAILED_IMAGE.

The definition status of *errmsg*, if present, remains unchanged if the execution of the reference is successful. If *errmsg* is present and an error condition occurs, *errmsg* becomes defined with an explanatory message describing the error.

Example

The following shows an example of how to increase the allocated size of X and keep the old values with only one copy of the old values. Using only assignment, a temporary variable named Y will be allocated and X assigned to Y. Then X will be deallocated and reallocated to be twice the size; then Y will be assigned to the first half of X. Finally, the temporary Y is deallocated.

```
! This program uses MOVE_ALLOC to make an allocated array X bigger and
! keep the old values of X in the variable X. Only one copy of the old values
! of X is needed.
```

```
      integer :: I, N = 2
      real, allocatable :: X(:), Y(:)
      allocate (X(N), Y(2*N))         ! Y is twice as big as X
      X = (/(I,I=1,N)/)       ! put "old values" into X
      Y = -1                  ! put different "old values" into Y
      print *, ' allocated of X is ', allocated (X)
      print *, ' allocated of Y is ', allocated (Y)
      print *, ' old X is ', X
      print *, ' old Y is ', Y
      Y (1:N) = X             ! copy all of X into the first half of Y
                              ! this is the only copying of values required
      print *, ' new Y is ', Y
      call move_alloc (Y, X)  ! X is now twice as big as it was, Y is
                              ! deallocated, the values were not copied from Y to X
      print *, ' allocated of X is ', allocated (X)
      print *, ' allocated of Y is ', allocated (Y)
      print *, ' new X is ', X
      end
```

The following shows the output for the above example:

```
 allocated of X is  T
 allocated of Y is  T
 old X is    1.000000       2.000000
 old Y is   -1.000000      -1.000000      -1.000000      -1.000000
 new Y is    1.000000       2.000000      -1.000000      -1.000000
 allocated of X is  T
 allocated of Y is  F
 new X is    1.000000       2.000000      -1.000000      -1.000000
```

ISO_FORTRAN_ENV Module

MVBITS

Elemental Intrinsic Subroutine (Generic): *Copies a sequence of bits (a bit field) from one location to another. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

`CALL MVBITS (from,frompos,len,to,topos)`

from	(Input) Integer. Can be of any integer type. It represents the location from which a bit field is transferred.
frompos	(Input) Can be of any integer type; it must not be negative. It identifies the first bit position in the field transferred from *from*. *frompos* + *len* must be less than or equal to BIT_SIZE(*from*).
len	(Input) Can be of any integer type; it must not be negative. It identifies the length of the field transferred from *from*.
to	(Input; output) Can be of any integer type, but must have the same kind parameter as *from*. It represents the location to which a bit field is transferred. *to* is set by copying the sequence of bits of length *len*, starting at position *frompos* of *from* to position *topos* of *to*. No other bits of *to* are altered.

topos	(Input) Can be of any integer type; it must not be negative. It identifies the starting position (within *to*) for the bits being transferred. *topos* + *len* must be less than or equal to BIT_SIZE(*to*).

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

You can also use the following specific routines:

BMVBITS	Arguments *from* and *to* must be INTEGER(1).
HMVBITS	Arguments *from* and *to* must be INTEGER(2).
IMVBITS	Arguments *from* and *to* must be INTEGER(2).
JMVBITS	Arguments *from* and *to* must be INTEGER(4).
KMVBITS	Arguments *from* and *to* must be INTEGER(8).

Example

If TO has the initial value of 6, its value after a call to MVBITS(7, 2, 2, TO, 0) is 5.

The following shows another example:

```
INTEGER(1) :: from = 13  ! 00001101
INTEGER(1) :: to = 6     ! 00000110
CALL MVBITS(from, 2, 2, to, 0) ! returns to = 00000111
END
```

NAMELIST

Statement: *Associates a name with a list of variables. This group name can be referenced in some input/output operations.*

Syntax

```
NAMELIST /group/ var-list[[,] /group/ var-list]...
```

group	Is the name of the group.
var-list	Is a list of variables (separated by commas) that are to be associated with the preceding group name. The variables can be of any data type.

Description

The namelist group name is used by namelist I/O statements instead of an I/O list. The unique group name identifies a list whose entities can be modified or transferred.

A variable can appear in more than one namelist group.

Each variable in *var-list* must be accessed by use or host association, or it must have its type, type parameters, and shape explicitly or implicitly specified in the same scoping unit. If the variable is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

You cannot specify an assumed-size array in a namelist group.

Only the variables specified in the namelist can be read or written in namelist I/O. It is not necessary for the input records in a namelist input statement to define every variable in the associated namelist.

The order of variables in the namelist controls the order in which the values appear on namelist output. Input of namelist values can be in any order.

If the group name has the PUBLIC attribute, no item in the variable list can have the PRIVATE attribute.

The group name can be specified in more than one NAMELIST statement in a scoping unit. The variable list following each successive appearance of the group name is treated as a continuation of the list for that group name.

Example

In the following example, D and E are added to the variables A, B, and C for group name LIST:

```
NAMELIST /LIST/ A, B, C

NAMELIST /LIST/ D, E
```

In the following example, two group names are defined:

```
CHARACTER*30 NAME(25)
NAMELIST /INPUT/ NAME, GRADE, DATE /OUTPUT/ TOTAL, NAME
```

Group name INPUT contains variables NAME, GRADE, and DATE. Group name OUTPUT contains variables TOTAL and NAME.

The following shows another example:

```
NAMELIST /example/ i1, l1, r4, r8, z8, z16, c1, c10, iarray
! The corresponding input statements could be:
&example
i1  = 11
l1  = .TRUE.
r4  = 24.0
r8  = 28.0d0
z8  = (38.0, 0.0)
z16 = (316.0d0, 0.0d0)
c1  = 'A'
c10 = 'abcdefghij'
iarray(8) = 41, 42, 43
/
```

A sample program, NAMELIST.F90, is included in the `<install-dir>/samples` subdirectory.

NARGS

Inquiry Intrinsic Function (Specific): *Returns the total number of command-line arguments, including the command. This function cannot be passed as an actual argument.*

Syntax

```
result = NARGS( )
```

Results

The result type is INTEGER(4). The result is the number of command-line arguments, including the command. For example, NARGS returns 4 for the command-line invocation of `PROG1 -g -c -a`.

Example

```
   INTEGER(2) result
   result = RUNQQ('myprog', '-c -r')
   END

!  MYPROG.F90 responds to command switches -r, -c,
!  and/or -d
INTEGER(4) count, num, i, status
CHARACTER(80) buf
REAL r1 / 0.0 /
COMPLEX c1 / (0.0,0.0) /
REAL(8) d1 / 0.0 /

num = 5
count = NARGS()
DO i = 1, count-1
   CALL GETARG(i, buf, status)
   IF (status .lt. 0) THEN
     WRITE (*,*) 'GETARG error - exiting'
     EXIT
   END IF
   IF (buf(2:status) .EQ.'r') THEN
     r1 = REAL(num)
     WRITE (*,*) 'r1 = ',r1
   ELSE IF (buf(2:status) .EQ.'c') THEN
     c1 = CMPLX(num)
     WRITE (*,*) 'c1 = ', c1
   ELSE IF (buf(2:status) .EQ.'d') THEN
     d1 = DBLE(num)
     WRITE (*,*) 'd1 = ', d1
   ELSE
     WRITE(*,*) 'Invalid command switch: ', buf (1:status)
   END IF
END DO
END
```

NEAREST

Elemental Intrinsic Function (Generic): *Returns the nearest different number (representable on the processor) in a given direction.*

Syntax

```
result = NEAREST (x, s)
```

x	(Input) Must be of type real.
s	(Input) Must be of type real and nonzero.

Results

The result type and kind are the same as *x*. The result has a value equal to the machine representable number that is different from and nearest to *x*, in the direction of the infinity with the same sign as *s*.

Example

If 3.0 and 2.0 are REAL(4) values, NEAREST (3.0, 2.0) has the value $3 + 2^{-22}$, which equals approximately 3.0000002. (For more information on the model for REAL(4), see Model for Real Data.

The following shows another example:

```
REAL(4) r1
REAL(8) r2, result
r1 = 3.0
result = NEAREST (r1, -2.0)
WRITE(*,*) result           ! writes 2.999999761581421

! When finding nearest to REAL(8), can't see
! the difference unless output in HEX
r2 = 111502.07D0
result = NEAREST(r2, 2.0)
WRITE(*,'(1x,Z16)') result  ! writes 40FB38E11EB851ED
result = NEAREST(r2, -2.0)
WRITE(*,'(1x,Z16)') result  ! writes 40FB38E11EB851EB
END
```

See Also

EPSILON

NEW_LINE

Inquiry Intrinsic Function (Generic): *Returns a new line character.*

Syntax

```
result = NEW_LINE(a)
```

a	(Input) Must be of type default character. It may be a scalar or an array.

Results

The result is a character scalar of length one with the same kind type parameter as a.

The result value is the ASCII newline character ACHAR(10).

NINT

Elemental Intrinsic Function (Generic): *Returns the nearest integer to the argument.*

Syntax

```
result = NINT (a[,kind])
```

a	(Input) Must be of type real.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *a* is greater than zero, NINT(*a*) has the value INT(*a*+ 0.5); if *a* is less than or equal to zero, NINT(*a*) has the value INT(*a*- 0.5).

Specific Name	Argument Type	Result Type
ININT	REAL(4)	INTEGER(2)
NINT [1, 2]	REAL(4)	INTEGER(4)
KNINT	REAL(4)	INTEGER(8)
IIDNNT	REAL(8)	INTEGER(2)
IDNINT [2, 3]	REAL(8)	INTEGER(4)
KIDNNT	REAL(8)	INTEGER(8)
IIQNNT	REAL(16)	INTEGER(2)
IQNINT[2, 4]	REAL(16)	INTEGER(4)
KIQNNT	REAL(16)	INTEGER(8)

[1]Or JNINT.

[2]The setting of compiler options specifying integer size can affect NINT, IDNINT, and IQNINT.

[3]Or JIDNNT. For compatibility with older versions of Fortran, IDNINT can also be specified as a generic function.

[4]Or JIQNNT. For compatibility with older versions of Fortran, IQNINT can also be specified as a generic function.

Example

NINT (3.879) has the value 4.

NINT (-2.789) has the value -3.

The following shows another example:

```
INTEGER(4) i1, i2
i1 = NINT(2.783) ! returns 3
i2 = IDNINT(-2.783D0) ! returns -3
```

ANINT

INT

NOFREEFORM

Statement: *Specifies that source code is in fixed-form format.*

For more information, see FREEFORM and NOFREEFORM.

NOFUSION

General Compiler Directive: *Prevents a loop from fusing with adjacent loops.*

Syntax

```
!DIR$ NOFUSION
```

The NOFUSION directive lets you fine tune your program on a loop-by-loop basis.

This directive should be placed immediately before the DO statement of the loop that should not be fused.

Example

Consider the following example that demonstrates use of the NOFUSION directive:

```
      subroutine sub (b,a,n)
      real a(n), b(n)
      do i=1,n
        a(i) = a(i) + b(i)
      enddo
!DIR$ NOFUSION
      do i=1,n
        a(i) = a(i) + 1
      enddo
      end
```

The following shows the same example, but it uses Standard Fortran array assignments, which allow implicit arrays:

```
      subroutine sub (b,a,n)
      real a(n), b(n)
      a = a + b
!DIR$ NOFUSION
      a = a + 1
      end
```

NON_RECURSIVE

Keyword: *Specifies that a subroutine or function does not call itself directly or indirectly.*

For more information, see RECURSIVE and NON_RECURSIVE.

NOOPTIMIZE

Statement: *Disables optimizations.*

For more information, see OPTIMIZE and NOOPTIMIZE.

NOPREFETCH

Statement: *Disables data prefetching.*

For more information, see PREFETCH and NOPREFETCH.

NORM2

Transformational Intrinsic Function (Generic):
Returns the L_2 norm of an array.

Syntax

```
result = NORM2 (x)
result = NORM2 (x, dim)
```

x	(Input) Must be a real array.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *x*.

Results

The result is of the same type and kind parameters as *x*.

The result is a scalar if *dim* is not specified; otherwise, the result has rank *n* - 1 and shape [d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n], where *n* is the rank of *x* and [d_1, d_2, ..., d_n] is the shape of *x*.

The result of NORM2 (*x*) has a value equal to a processor-dependent approximation to the generalized L_2 norm of *x*, which is the square root of the sum of the squares of the elements of *x*.

The result of NORM2 (*x*, DIM=*dim*) has a value equal to that of NORM2 (*x*) if *x* has rank one.

Otherwise, the value of element (s_1, s_2, .., s_{dim-1}, s_{dim+1}, ... s_n) of the result is equal to NORM2 (*x* (s_1, s_2, .., s_{dim-1}, :, s_{dim+1}, ... s_n)).

It is recommended that the processor compute the result without undue overflow or underflow.

Example

The value of NORM2 ([3.0, 4.0]) is 5.0 (approximately).

If X has the value:

```
[ 1.0  2.0 ]
[ 3.0  4.0 ]
```

then the value of NORM2 (X, DIM=1) is approximately [3.162, 4.472] and the value of NORM2 (X, DIM=2) is approximately [2.236,5.0].

NOSTRICT

Statement: *Enables language features not found in the language standard specified on the command line.*

For more information, see STRICT and NOSTRICT.

NOT

Elemental Intrinsic Function (Generic): *Returns the logical complement of the argument.*

Syntax

```
result = NOT (i)
```

i (Input) Must be of type integer.

Results

The result type and kind are the same as *i*. The result value is obtained by complementing *i* bit-by-bit according to the following truth table:

```
INOT (I)
  1      0
  0      1
```

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Specific Name	Argument Type	Result Type
BNOT	INTEGER(1)	INTEGER(1)
INOT[1]	INTEGER(2)	INTEGER(2)
JNOT	INTEGER(4)	INTEGER(4)
KNOT	INTEGER(8)	INTEGER(8)

[1]Or HNOT.

Example

If I has a value equal to 10101010 (base 2), NOT (I) has the value 01010101 (base 2).

The following shows another example:

```
INTEGER(2) i(2), j(2)
i = (/4, 132/)          ! i(1) = 0000000000000100
                        ! i(2) = 0000000010000100
j = NOT(i)              ! returns (-5,-133)
                        ! j(1) = 1111111111111011
                        ! j(2) = 1111111101111011
```

NOTHING

OpenMP* Fortran Compiler Directive: *Provides documentary clarity in conditionally compiled code or conditional OpenMP* code. It has no effect on the semantics or execution of the program. This feature is only available for ifx.*

Syntax

```
!$OMP NOTHING
```

The NOTHING directive is a utility directive that provides documentary clarity in conditionally compiled code or conditional OpenMP code. The statement by itself does nothing and has no effect on program results or execution sequence.

The directive is pure, so it can appear in a Fortran PURE procedure.

In a conditional context, the NOTHING directive can be used to verify that no OpenMP actions are taken in that conditional block of code.

Example

The following subroutine tests the loop trip count. If it is sufficiently large, a parallelized, vectorized loop is executed. If the loop trip count is small, no OpenMP transformation is performed, as noted by use of the OpenMP NOTHING directive. Otherwise, an OpenMP SIMD directive is applied to vectorize the loop.

```
SUBROUTINE sub (a, b, c, d, n)
INTEGER           :: i, n
REAL,DIMENSION(n) :: a, b, c, d
IF (n > 4096)
  !$OMP PARALLEL DO SIMD
    DO i = 1, n
      a(i) = a(i) + b(i) * c(i) - d(i)
    END DO
  !$OMP END PARALLEL DO SIMD
ELSE IF (N < 4)
  !$OMP NOTHING     ! Run a scalar loop
    DO i = 1, n
      a(i) = a(i) + b(i) * c(i) - d(i)
    END DO
ELSE
  !$OMP SIMD
    DO i = 1, n
      a(i) = a(i) + b(i) * c(i) - d(i)
    END DO
  !$OMP END SIMD
END SUBROUTINE sub
```

NOUNROLL

Statement: *Disables the unrolling of a DO loop.*

For more information, see UNROLL and NOUNROLL.

NOUNROLL_AND_JAM

Statement: *Hints to the compiler to disable loop unrolling and jamming.*

For more information, see UNROLL_AND_JAM and NOUNROLL_AND_JAM.

NOVECTOR

Statement: *Disables vectorization of a DO loop.*

For more information, see VECTOR and NOVECTOR.

NOWAIT Clause

Parallel Directive Clause: *Specifies that threads may resume execution before the execution of the region completes.*

Syntax

```
NOWAIT
```

When you specify this clause, it removes the synchronization barrier implied at the end of the region.

Note that NOWAIT can also be specified as a keyword in several directives.

At most one NOWAIT clause or keyword can appear in a directive that allows the clause or keyword.

If the NOWAIT clause appears in the beginning directive of a construct, the NOWAIT keyword cannot appear in the end directive of the same construct. If a NOWAIT keyword appears in the END directive of a construct, a NOWAIT clause cannot appear in the matching directive that begins the construct.

NULL

Transformational Intrinsic Function (Generic): *Initializes a pointer as disassociated when it is declared.*

Syntax

```
result = NULL ([ mold])
```

mold (Optional) Must be a pointer; it can be of any type. Its pointer association status can be associated, disassociated, or undefined. If its status is associated, the target does not have to be defined with a value.

Results

The result type and kind are the same as *mold*, if present; otherwise, it is determined as follows:

If NULL ( ) Appears...	Type is Determined From...
On the right side of pointer assignment	The pointer on the left side
As initialization for an object in a declaration	The object
As default initialization for a component	The component
In a structure constructor	The corresponding component
As an actual argument	The corresponding dummy argument

If NULL ( ) Appears...	Type is Determined From...
In a DATA statement	The corresponding pointer object

The result is a pointer with disassociated association status.

Caution
If you use module IFWIN or IFWINTY, you will have a name conflict if you use the NULL intrinsic. To avoid this problem, rename the integer parameter constant NULL to something else; for example:

```
USE IFWIN, NULL0 => NULL
```

This example lets you use both NULL0 and NULL( ) in the same program unit with no conflict.

Example

Consider the following:

```
INTEGER, POINTER :: POINT1 => NULL( )
```

This statement defines the initial association status of POINT1 to be disassociated.

NULLIFY

Statement: *Disassociates a pointer from a target.*

Syntax

NULLIFY (*pointer-object*[,*pointer-object*]...)

pointer-object — Is a structure component or the name of a variable; it must be a pointer (have the POINTER attribute).

Description

The initial association status of a pointer is undefined. You can use NULLIFY to initialize an undefined pointer, giving it disassociated status. Then the pointer can be tested using the intrinsic function ASSOCIATED.

Example

The following is an example of the NULLIFY statement:

```
REAL, TARGET  :: TAR(0:50)
REAL, POINTER :: PTR_A(:), PTR_B(:)
PTR_A => TAR
PTR_B => TAR
...
NULLIFY(PTR_A)
```

After these statements are executed, PTR_A will have disassociated status, while PTR_B will continue to be associated with variable TAR.

The following shows another example:

```
!    POINTER2.F90    Pointing at a Pointer and Target
!DIR$ FIXEDFORMLINESIZE:80

     REAL, POINTER :: arrow1 (:)
     REAL, POINTER :: arrow2 (:)
     REAL, ALLOCATABLE, TARGET :: bullseye (:)
```

```
ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1

arrow2 => arrow1
IF (ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow2

NULLIFY (arrow2)
IF (.NOT.ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is not pointed.'
WRITE (*,'( 1x,a,7f8.0)') 'pointer',arrow1
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

END
```

NUM_IMAGES

Transformational Intrinsic Function (Generic):
Returns the number of images on the current or specified team.

Syntax

`result = NUM_IMAGES()`

`result = NUM_IMAGES (team)result = NUM_IMAGES (team_number)`

team	(Input) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV. Fortran 2018 requires the team specified by *team* to be the current or an ancestor team. `ifx` and `ifort` accept any team variable defined by a FORM TEAM statement, and will diagnose use of a team variable which does not describe the current or an ancestor team with a runtime message when the `check standard-behavior` compiler option is selected.
team_number	(Input) Must be an integer scalar. It must identify the initial team (-1), or a valid team number of a team created by the same execution of the FORM TEAM statement that created the current team executing the function reference (a sibling of the current team).

Results

The result type is default integer. The result is the number of images on the current or specified team.

If neither *team* nor *team_number* are specified, the team is the current team. *team* and *team_number* may not both be specified.

You can specify a compiler option or environment variable to modify the number of images. If both are specified, the environment variable setting overrides the compiler option setting.

A compiler option must be specified to enable coarrays. If it is not specified and you use this intrinsic function, an error occurs.

Example

In the following example, image 1 is used to read data. The other images then copy the data:

```
REAL :: R[*]

IF (THIS_IMAGE()==1) THEN
   READ (7,*) R
   DO I = 2, NUM_IMAGES()
      R[I] = R
   END DO
END IF
SYNC ALL
```

FORM TEAM

O to P

This section describes language features that start with O or P.

O to P

OBJCOMMENT

General Compiler Directive: *Specifies a library search path in an object file.*

Syntax

```
!DIR$ OBJCOMMENT LIB: library
```

library	Is a character constant specifying the name and, if necessary, the path of the library that the linker is to search.

The linker searches for the library named in OBJCOMMENT as if you named it on the command line, that is, before default library searches. You can place multiple library search directives in the same source file. Each search directive appears in the object file in the order it is encountered in the source file.

If the OBJCOMMENT directive appears in the scope of a module, any program unit that uses the module also contains the directive, just as if the OBJCOMMENT directive appeared in the source file using the module.

If you want to have the OBJCOMMENT directive in a module, but do not want it in the program units that use the module, place the directive outside the module that is used.

Example

```
!  MOD1.F90
MODULE a
!DIR$ OBJCOMMENT LIB: "opengl32.lib"
END MODULE a

!  MOD2.F90
!DIR$ OBJCOMMENT LIB: "graftools.lib"
MODULE b
```

```
!
END MODULE b

!  USER.F90
PROGRAM go
   USE a    ! library search contained in MODULE a
            !   included here
   USE b    ! library search not included
END
```

Equivalent Compiler Options

OPEN

Statement: *Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.*

Syntax

`OPEN ([UNIT=] io-unit[, FILE= name] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var],slist)`

io-unit — Is an external unit specifier.

name — Is a character or numeric expression specifying the name of the file to be connected. For more information, see FILE Specifier.

label — Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

msg-var — Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

i-var — Is a scalar integer variable that is defined as a positive integer (the number of the error message) if an error occurs, a negative integer if an end-of-file record is encountered, and zero if no error occurs. For more information, see I/O Status Specifier.

slist — Is one or more of the following OPEN specifiers in the form *specifier*= *value* or *specifier* (each specifier can appear only once):

ACCESS	DECIMAL	NAME	ROUND
ACTION	DEFAULTFILE	NEWUNIT	SHARE
ASSOCIATEVARIABLE	DELIM	NOSHARED	SHARED
ASYNCHRONOUS	DISPOSE	ORGANIZATION	SIGN
BLANK	ENCODING	PAD	STATUS
BLOCKSIZE	FILE	POSITION	TITLE

BUFFERCOUNT	FORM	READONLY	TYPE
BUFFERED	IOFOCUS	RECL	USEROPEN
CARRIAGECONTROL	MAXREC	RECORDSIZE	
CONVERT	MODE	RECORDTYPE	

The OPEN specifiers and their acceptable values are summarized in the OPEN Statement Overview.

The control specifiers that can be specified in an OPEN statement are discussed in I/O Control List in the *Language Reference*.

Description

The control specifiers ([UNIT=] *io-unit*, ERR= *label*, and IOSTAT= *i-var*) and OPEN specifiers can appear anywhere within the parentheses following OPEN. However, if the UNIT specifier is omitted, the *io-unit* must appear first in the list.

If you specify BLANK=, DECIMAL=, PAD=, ROUND=, or SIGN=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Specifier values that are scalar numeric expressions can be any integer or real expression. The value of the expression is converted to integer data type before it is used in the OPEN statement.

If the NEWUNIT= specifier does not appear, an *io-unit* must be specified. If the keyword UNIT= is omitted, the *io-unit* must be first in the control list.

If the NEWUNIT= specifier appears, an *io-unit* must not be specified.

If the NEWUNIT= specifier appears, either the FILE= specifier or the STATUS=SCRATCH specifier must also appear.

Only one unit at a time can be connected to a file, but multiple OPENs can be performed on the same unit. If an OPEN statement is executed for a unit that already exists, the following occurs:

- If FILE is not specified, or FILE specifies the same file name that appeared in a previous OPEN statement, the current file remains connected.

  If the file names are the same, the values for the BLANK, CARRIAGECONTROL, CONVERT, DELIM, DISPOSE, ERR, IOSTAT, and PAD specifiers can be changed. Other OPEN specifier values cannot be changed, and the file position is unaffected.
- If FILE specifies a different file name, the previous file is closed and the new file is connected to the unit.

The ERR and IOSTAT specifiers from any previously executed OPEN statement have no effect on any currently executing OPEN statement. If an error occurs, no file is opened or created.

Secondary operating system messages do not display when IOSTAT is specified. To display these messages, remove IOSTAT or use a platform-specific method.

Example

You can specify character values at runtime by substituting a character expression for a specifier value in the OPEN statement. The character value can contain trailing blanks but not leading or embedded blanks; for example:

```
CHARACTER*6 FINAL /' '/
...
IF (expr) FINAL = 'DELETE'
OPEN (UNIT=1, STATUS='NEW', DISP=FINAL)
```

The following statement creates a new sequential formatted file on unit 1 with the default file name fort.1:

```
 OPEN (UNIT=1, STATUS='NEW', ERR=100)
```

The following example opens the existing file /usr/users/someone/test.dat:

```
  OPEN (unit=10, DEFAULTFILE='/usr/users/someone/', FILE='test.dat',
 1     FORM='FORMATTED', STATUS='OLD')
```

The following example opens a new file:

```
! Prompt user for a filename and read it:
CHARACTER*64 filename
WRITE (*, '(A\)') ' enter file to create: '
READ (*, '(A)') filename
! Open the file for formatted sequential access as unit 7.
! Note that the specified access need not have been specified,
! since it is the default (as is "formatted").
OPEN (7, FILE = filename, ACCESS = 'SEQUENTIAL', STATUS = 'NEW')
```

The following example opens an existing file called DATA3.TXT:

```
! Open a file created by an editor, "DATA3.TXT", as unit 3:
OPEN (3, FILE = 'DATA3.TXT')
```

OPEN Statement Overview

OPTIONAL

Statement and Attribute: *Permits dummy arguments to be omitted in a procedure reference.*

Syntax

The OPTIONAL attribute can be specified in a type declaration statement or an OPTIONAL statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] OPTIONAL [, *att-ls*] :: *d-arg*[, *d-arg*]...

Statement:

OPTIONAL [::] *d-arg*[, *d-arg*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
d-arg	Is the name of a dummy argument.

Description

The OPTIONAL attribute can only appear in the scoping unit of a subprogram or an interface body, and can only be specified for dummy arguments. If the procedure has the BIND attribute, a dummy argument with the OPTIONAL attribute cannot also have the VALUE attribute.

A dummy argument is "present" if it associated with an actual argument that is itself present. A dummy argument that is not optional must be present. You can use the PRESENT intrinsic function to determine whether an optional dummy argument is associated with an actual argument.

To call a procedure that has an optional argument, you must use an explicit interface.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Example

The following example shows a type declaration statement specifying the OPTIONAL attribute:

```
SUBROUTINE TEST(A)
REAL, OPTIONAL, DIMENSION(-10:2) :: A
END SUBROUTINE
```

The following is an example of the OPTIONAL statement:

```
SUBROUTINE TEST(A, B, L, X)
  OPTIONAL :: B
  INTEGER A, B, L, X
  IF (PRESENT(B)) THEN        ! Printing of B is conditional
    PRINT *, A, B, L, X       !   on its presence
  ELSE
    PRINT *, A, L, X
  ENDIF
END SUBROUTINE

INTERFACE
  SUBROUTINE TEST(ONE, TWO, THREE, FOUR)
    INTEGER ONE, TWO, THREE, FOUR
    OPTIONAL :: TWO
  END SUBROUTINE
END INTERFACE

INTEGER I, J, K, L
I = 1
J = 2
K = 3
L = 4

CALL TEST(I, J, K, L)            ! Prints:  1  2  3  4
CALL TEST(I, THREE=K, FOUR=L)    ! Prints:  1  3  4
END
```

Note that in the second call to subroutine TEST, the second positional (optional) argument is omitted. In this case, all following arguments must be keyword arguments.

The following shows another example:

```
SUBROUTINE ADD (a,b,c,d)
  REAL             a, b, d
  REAL, OPTIONAL :: c
  IF (PRESENT(c)) THEN
    d = a + b + c + d
  ELSE
```

```
    d = a + b + d
  END IF
END SUBROUTINE
```

Consider the following:

```
SUBROUTINE EX (a, b, c)
REAL, OPTIONAL :: b,c
```

This subroutine can be called with any of the following statements:

```
CALL EX (x, y, z)   !All 3 arguments are passed.
CALL EX (x)         !Only the first argument is passed.
CALL EX (x, c=z)    !The first optional argument is omitted.
```

Note that you *cannot* use a series of commas to indicate omitted optional arguments, as in the following example:

```
CALL EX (x,,z)   !Invalid statement.
```

This results in a compile-time error.

OPTIMIZE and NOOPTIMIZE

General Compiler Directive: *Enables or disables optimizations for the program unit.*

Syntax

```
!DIR$ OPTIMIZE[: n]

!DIR$ NOOPTIMIZE
```

n	Is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options `O0`, `O1`, `O2`, and `O3`. If *n* is omitted, the default is 2, which corresponds to option `O2`.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to `-O0` (Linux*) and `/Od` (Windows*).

The procedure is compiled with an optimization level equal to the smaller of *n* and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with compiler option `O3`, this procedure is compiled at `O0` while the rest of the program is compiled at `O3`.

Syntax Rules for Compiler Directives

O compiler option

OPTIONS Directive

General Compiler Directive: *Affects data alignment and warnings about data alignment. Also controls whether a target attribute is assigned to a section of program declarations.*

Syntax

```
!DIR$ OPTIONS option[option]
...
!DIR$ END OPTIONS
```

option Is one (or more) of the following:

`/WARN=[NO]ALIGNMENT` Controls whether warnings are issued by the compiler for data that is not naturally aligned. By default, you receive compiler messages when misaligned data is encountered (/WARN=ALIGNMENT).

`/[NO]ALIGN[= p]` Controls alignment of fields in record structures and data items in common blocks. The fields and data items can be naturally aligned (for performance reasons) or they can be packed together on arbitrary byte boundaries.

p Is a specifier with one of the following forms:

`[class=]rule`

`(class= rule,...)`

`ALL`

`NONE`

class Is one of the following keywords:

- `COMMONS`: For common blocks
- `RECORDS`: For records
- `STRUCTURES`: A synonym for RECORDS

rule Is one of the following keywords:

PACKED
: Packs fields in records or data items in common blocks on arbitrary byte boundaries.

NATURAL
: Naturally aligns fields in records and data items in common blocks on up to 64-bit boundaries (inconsistent with the Standard Fortran).

  This keyword causes the compiler to naturally align all data in a common block, including INTEGER(KIND=8), REAL(KIND=8), and all COMPLEX data.

STANDARD
: Naturally aligns data items in

	common blocks on up to 32-bit boundaries (consistent with the Standard Fortran). This keyword only applies to common blocks; so, you can specify /ALIGN=COMMONS=STANDARD, but you cannot specify /ALIGN=STANDARD.
ALL	Is the same as specifying OPTIONS /ALIGN, OPTIONS /ALIGN=NATURAL, and OPTIONS /ALIGN=(RECORDS=NATURAL,COMMONS=NATURAL).
NONE	Is the same as specifying OPTIONS /NOALIGN, OPTIONS /ALIGN=PACKED, and OPTIONS /

ALIGN=(RECORDS=PACKED,COMMONS=PACKED).

The OPTIONS (and accompanying END OPTIONS) directives must come after OPTIONS, SUBROUTINE, FUNCTION, and BLOCK DATA statements (if any) in the program unit, and before the executable part of the program unit.

The OPTIONS directive supersedes the compiler option `align`.

For performance reasons, Intel® Fortran aligns local data items on natural boundaries. However, EQUIVALENCE, COMMON, RECORD, and STRUCTURE data declaration statements can force misaligned data. If /WARN=NOALIGNMENT is specified, warnings will not be issued if misaligned data is encountered.

NOTE
Misaligned data significantly increases the time it takes to execute a program. As the number of misaligned fields encountered increases, so does the time needed to complete program execution. Specifying /ALIGN (or compiler option `align`) minimizes misaligned data.

If you want aligned data in common blocks, do one of the following:

- Specify OPTIONS /ALIGN=COMMONS=STANDARD for data items up to 32 bits in length.
- Specify OPTIONS /ALIGN=COMMONS=NATURAL for data items up to 64 bits in length.
- Place source data declarations within the common block in descending size order, so that each data item is naturally aligned.

If you want packed, unaligned data in a record structure, do one of the following:

- Specify OPTIONS /ALIGN=RECORDS=PACKED.
- Place source data declarations in the record structure so that the data is naturally aligned.

Example

Consider the following:

```
! directives can be nested up to 100 levels
  !DIR$ OPTIONS /ALIGN=PACKED     ! Start of Group A
    declarations
  !DIR$ OPTIONS /ALIGN=RECO=NATU     ! Start of nested Group B
    more declarations
  !DIR$ END OPTIONS                  ! End of Group B
    still more declarations
  !DIR$ END OPTIONS                ! End of Group A
```

The OPTIONS specification for Group B only applies to RECORDS; common blocks within Group B will be PACKED. This is because COMMONS retains the previous setting (in this case, from the Group A specification).

align compiler option

OPTIONS Statement

Statement: *Overrides or confirms the compiler options in effect for a program unit.*

Syntax

`OPTIONS option[option...]`

option

Is one of the following:

/ASSUME =	[NO]UNDERSCORE
/CHECK =	ALL
	[NO]BOUNDS
	NONE
/NOCHECK	
/CONVERT =	BIG_ENDIAN
	CRAY
	FDX
	FGX
	IBM
	LITTLE_ENDIAN
	NATIVE
	VAXD
	VAXG
/[NO]EXTEND_SOURCE	
/[NO]F77	
/[NO]I4	
/[NO]RECURSIVE	

Note that an option must always be preceded by a slash (/).

Some OPTIONS statement options are equivalent to compiler options.

The OPTIONS statement must be the first statement in a program unit, preceding the PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

OPTIONS statement options override compiler options, but only until the end of the program unit for which they are defined. If you want to override compiler options in another program unit, you must specify the OPTIONS statement before that program unit.

Example

The following are valid OPTIONS statements:

```
OPTIONS /CHECK=ALL/F77
OPTIONS /I4
```

OPEN Statement CONVERT Method

OPTIONS Statement Method

For details on compiler options, see your *Compiler Options* reference

OR

Elemental Intrinsic Function (Generic): *Performs a bitwise inclusive OR on its arguments.*

See IOR.

Example

```
INTEGER i
i = OR(3, 10)   ! returns 11
```

ORDER Clause

Parallel Directive Clause: *Specifies an order of execution for iterations of loops associated with a loop directive. This feature is only available for ifx.*

Syntax

ORDER ([*order-modifier*:] CONCURRENT)

order-modifier	Is either REPRODUCIBLE or UNCONSTRAINED.

The ORDER clause provides an execution order schedule for iterations of loops associated with the loop construct the ORDER clause appears in. CONCURRENT indicates that the iterations of the loop may execute in any order, including concurrently.

The *order-modifier* affects the scheduling of loop iterations. If *order-modifier* is present and is REPRODUCIBLE, or if *order-modifier* is not specified, the construct has a reproducible schedule. If *order-modifier* is UNCONSTRAINED, the scheduling of loop iterations is not reproducible.

Inside a region that corresponds to a construct specifying the ORDER clause, the only constructs that are permitted are LOOP, SIMD, PARALLEL, or a combined construct whose first construct is PARALLEL. The region cannot contain calls to OpenMP* runtime API procedures, and it cannot contain calls to procedures that contain OpenMP directives.

When a program references a THREADPRIVATE variable from within a region associated with a construct specifying ORDER, the behavior is undefined.

See Also

Clauses used in Multiple OpenMP directives

ORDERED

OpenMP* Fortran Compiler Directive: *Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations, or, as a stand-alone directive, it specifies cross-iteration dependences in a doacross loop nest.*

Syntax

It takes one of the following forms:

Form 1:

```
!$OMP ORDERED [clause [[,] clause ]]
   loosely-structured-block
!$OMP END ORDERED
-or-
!$OMP ORDERED [clause [[,] clause ]]
```

strictly-structured-block

[!$OMP END ORDERED]

Form 2:

!$OMP ORDERED *clause* [[,] *clause*]...]

Form 1 *clause*

Is an optional clause. It can be one of the following:

- SIMD [*keyword* [, *keyword*]...]

  Binds the ordered region to the innermost SIMD or worksharing loop region. With ifort, you can specify one or more keywords to apply an ordered region inside a SIMD loop. Possible values are:

  - MONOTONIC (*list* [: *linear-step*])

    The *list* is a comma-separated list of one or more integer scalar variables. The *linear-step* is a positive, integer, scalar constant expression. The *linear-step* expression must be invariant (it must not be changed) during the execution of the associated construct. If *linear-step* is omitted, a default value of 1 is used.

    Multiple MONOTONIC keywords may appear; they are merged into a single MONOTONIC list. You cannot specify multiple MONOTONIC keywords with different *linear-step*s for the same variable.

    Each *list* item may have the POINTER attribute but not the ALLOCATABLE attribute. Each list item must comply with PRIVATE clause semantics.
  - OVERLAP (*expr*)

    The *expr* is an integer expression. It specifies a block of code that has to be executed in scalar mode for overlapping loop index values and in parallel for different loop index values within the SIMD loop.

    The OVERLAP keyword can appear no more than once in an ORDERED directive.
- THREADS

  Applies an ordered region inside a PARALLEL DO loop. If no *clause* is specified, the directive behaves as if THREADS was specified.

At most one THREADS clause can appear in an ORDERED construct. At most one SIMD clause can appear in an ORDERED construct.

Form 2 *clause*

Is one of the following:

- DOACROSS (SOURCE : [OMP_CUR_ITERATION])
- DOACROSS (SINK : *vec*)
- DOACROSS (SINK : OMP_CUR_ITERATION – 1)
- DEPEND (SOURCE) - deprecated
- DEPEND (SINK : *vec*) - deprecated

  The above DEPEND clauses have been deprecated and replaced by DOACROSS clauses. The semantics of DEPEND and DOACROSS are similar.

At most one DOACROSS clause can appear in an ORDERED construct if SOURCE is specified.

	Either DOACROSS (SINK : vec) clauses or DOACROSS (SOURCE :) clauses can appear in an ORDERED construct, but not both. *vec* is an iteration vector that specifies the iteration of the loop or loop nest that satisfies the dependency. If *vec* has *n* elements, the innermost loop-associated construct that encloses the ORDERED directive must specify an ORDERED clause whose parameter value is also *n*. The predefined dependence vector OMP_CUR_ITERATION specifies the current iteration. If DOACROSS (SINK : OMP_CUR_ITERATION – 1) appears in a triply nested loop with loop indices i, j, and k, the effect is the same as if DOACROSS (SINK : i-1, j-1, k-1) was specified.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for an ORDERED construct is the current team. An ordered region binds to the innermost enclosing loop region or the innermost enclosing SIMD region if the SIMD clause is present.

A doacross loop nest is a loop nest that has cross-iteration dependences. An iteration is dependent on one or more lexicographically earlier iterations. The ORDERED clause parameter on a loop directive identifies the loops associated with the doacross loop nest.

An ORDERED directive with no *clause* or with the THREADS clause specified can appear only in the dynamic extent of a DO or PARALLEL DO directive. The DO directive to which the ordered section binds *must* have the ORDERED clause specified.

An iteration of a loop using a DO directive must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.

One thread is allowed in an ordered section at a time. Threads are allowed to enter in the order of the loop iterations. No thread can enter an ordered section until it can be guaranteed that all previous iterations have completed or will never execute an ordered section. This sequentializes and orders code within ordered sections while allowing code outside the section to run in parallel.

Ordered sections that bind to different DO directives are independent of each other.

If the SIMD clause is specified, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

You can only specify the SIMD clause (!$OMP ORDERED SIMD) within an !$OMP SIMD loop or an !$OMP DECLARE SIMD procedure.

When a thread executing any subsequent iteration encounters an ORDERED construct with one or more DOACROSS clauses specifying SINK, it waits until its dependences on all valid iterations specified by the DOACCROSS clauses are satisfied before it completes execution of the ORDERED region. A specific dependence is satisfied when a thread executing the corresponding iteration encounters an ORDERED construct with a DOACCROSS clause specifying SOURCE.

For MONOTONIC (*list*: *linear-step*), the following rules apply:

- The value of the new *list* item on each iteration of the associated SIMD loop corresponds to the value of the original *list* item before entering the associated loop, plus the number of the iterations for which the conditional update happens prior to the current iteration, times *linear-step*.
- The value corresponding to the sequentially last iteration of the associated loop is assigned to the original *list* item.

- A *list* item must not be used in statements that lexically precede the ORDERED SIMD to which it is bound, that is, in the region from the OMP SIMD to the OMP ORDERED SIMD. A *list* item must not be modified outside the ORDERED SIMD to which it is bound, that is, in the region from the OMP END ORDERED to the OMP END SIMD.

NOTE
This construct is not supported within a TARGET or a DECLARE TARGET region if the target hardware is spir64.

Examples

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
      DO I=LB,UB,ST
        CALL WORK(I)
      END DO
      ...
      SUBROUTINE WORK(K)
!$OMP ORDERED
      WRITE(*,*) K
!$OMP END ORDERED
```

Ordered SIMD sections are useful for resolving cross-iteration data dependencies in otherwise data-parallel computations. For example, it may handle histogram updates such the following:

```
!$OMP SIMD
      DO I=0,N
        AMOUNT = COMPUTE_AMOUNT(I)
        CLUSTER = COMPUTE_CLUSTER(I)  ! Multiple I's may belong to the
                  !  same cluster within SIMD chunk
!$OMP ORDERED SIMD
        TOTALS(CLUSTER) = TOTALS(CLUSTER) + AMOUNT  ! Requires ordering to
                          !  process multiple updates
                          !  to the same cluster
!$OMP END ORDERED
      END DO
!$OMP END SIMD
```

The MONOTONIC keyword in the OMP ORDERED SIMD directive specifies that the body of a loop must be executed in the natural order of the loop iterations. In the following example, the block of code in the OMP ORDERED SIMD is executed in the ascending, monotonic order of the loop index I:

```
COUNT = 0
!$OMP SIMD
DO I = 1, N
  IF (COND(I)) THEN
!$OMP ORDERED SIMD MONOTONIC (COUNT:1)
    A(COUNT) = A(COUNT) + B(I)
    COUNT = COUNT + 1
    B(I) = C(COUNT)
!$OMP END ORDERED
  END IF
END DO
!$OMP END SIMD
```

In the following example, the OVERLAP keyword specifies that the block of code after the OMP ORDERED SIMD directive may contain overlap between the loop iterations:

```
!$OMP SIMD
DO I = 1, N
  INX = INDEX(I)
!$OMP ORDERED SIMD OVERLAP (INX)
  A(INX) = A(INX) + B(I)
!$OMP END ORDERED
END DO
!$OMP END SIMD
```

Parallel Processing Model for information about Binding Sets

OUT_OF_RANGE

Elemental Intrinsic Function (Generic): *Indicates if a value can be safely converted to a specified type.*

Syntax

`result = OUT_OF_RANGE (value, mold [, round])`

value	(Input) Must be of type integer or real.
mold	(Input) Must be a scalar of type real or integer. It need not be defined if it is a variable.
round	(Input; optional) Must be a scalar logical. *round* can only be present if *value* is type real and *mold* is type integer.

Results

The result type is default logical.

If *round* is not present or has the value .false., and *mold* is an integer type, the result is .true. if *value* is a NaN or an IEEE infinity, or if the integer with the largest magnitude between zero and *value* (inclusively) is not representable by an object with the type and kind of *mold*.

If *round* has the value .true. and *mold* is an integer type, the result is .true. if *value* is a NaN or an IEEE infinity, or if the integer value nearest *value*, or the integer of greater magnitude if the two integers are equally near *value*, is not representable by an object with the type and kind of *mold*.

Otherwise, the result is .true. if *value* is a NaN or IEEE infinity that is not supported by an object of type and kind of *mold*, or X is a finite number and the result of rounding value to the extended model for the kind of *mold* has a magnitude larger than that of the largest finite number with the same size as *value* that can be represented by objects with the type and kind of *mold*.

Example

If J8 is a variable with type INTEGER (KIND=1), OUT_OF_RANGE (-128.5, J8) will have the result .false. and OUT_OF_RANGE (-128.5, J8, .TRUE.) will have the value .true..

PACK Directive

General Compiler Directive: *Specifies the memory alignment of derived-type items (and record structure items).*

Syntax

```
!DIR$ PACK[: {1 | 2 | 4 | 8} ]
```

Items of derived types, unions, and structures are aligned in memory on the smaller of two sizes: the size of the type of the item, or the current alignment setting. The current alignment setting can be 1, 2, 4, or 8 bytes. The default initial setting is 8 bytes (unless compiler option vms or align rec *n* bytes is specified). By reducing the alignment setting, you can pack variables closer together in memory.

The PACK directive lets you control the packing of derived-type or record structure items inside your program by overriding the current memory alignment setting.

For example, if PACK:1 is specified, all variables begin at the next available byte, whether odd or even. Although this slightly increases access time, no memory space is wasted. If PACK:4 is specified, INTEGER(1), LOGICAL(1), and all character variables begin at the next available byte, whether odd or even. INTEGER(2) and LOGICAL(2) begin on the next even byte; all other variables begin on 4-byte boundaries.

If the PACK directive is specified without a number, packing reverts to the compiler option setting (if any), or the default setting of 8.

The directive can appear anywhere in a program before the derived-type definition or record structure definition. It cannot appear *inside* a derived-type or record structure definition.

Example

```
! Use 4-byte packing for this derived type
! Note PACK is used outside of the derived type definition
!DIR$ PACK:4
TYPE pair
   INTEGER a, b
END TYPE
! revert to default or compiler option
!DIR$ PACK
```

See Also

vms compiler option
Equivalent Compiler Options

PACK Function

Transformational Intrinsic Function (Generic):
Takes elements from an array and packs them into a rank-one array under the control of a mask.

Syntax

```
result = PACK (array,mask[,vector])
```

array	(Input) Must be an array. It may be of any data type.
mask	(Input) Must be of type logical and conformable with *array*. It determines which elements are taken from *array*.

vector	(Input; optional) Must be a rank-one array with the same type and type parameters as *array*. Its size must be at least *t*, where *t* is the number of true elements in *mask*. If *mask* is a scalar with value true, *vector* must have at least as many elements as there are in array. Elements in *vector* are used to fill out the result array if there are not enough elements selected by *mask*.

Results

The result is a rank-one array with the same type and kind parameters as *array*. If *vector* is present, the size of the result is that of *vector*. Otherwise, the size of the result is the number of true elements in *mask*, or the number of elements in *array* (if *mask* is a scalar with value true).

Elements in *array* are processed in array element order to form the result array. Element i of the result is the element of *array* that corresponds to the ith true element of *mask*. If *vector* is present and has more elements than there are true values in *mask*, any result elements that are empty (because they were not true according to *mask*) are set to the corresponding values in *vector*.

Example

N is the array

```
 [ 0  8  0 ]
 [ 0  0  0 ]
 [ 7  0  0 ].
```

PACK (N, MASK=N .NE. 0, VECTOR=(/1, 3, 5, 9, 11, 13/)) produces the result (7, 8, 5, 9, 11, 13).

PACK (N, MASK=N .NE. 0) produces the result (7, 8).

The following shows another example:

```
INTEGER array(2, 3), vec1(2), vec2(5)
LOGICAL mask (2, 3)
array = RESHAPE((/7, 0, 0, -5, 0, 0/), (/2, 3/))
mask = array .NE. 0
!  array is  7  0 0  and mask is  T F F
!            0 -5 0               F T F
VEC1 = PACK(array, mask)      ! returns ( 7, -5 )
VEC2 = PACK(array, array .GT. 0, VECTOR= (/1,2,3,4,5/))
!  returns ( 7, 2, 3, 4, 5 )
```

UNPACK

PACKTIMEQQ

Portability Subroutine: *Packs time and date values.*

Module

USE IFPORT

Syntax

CALL PACKTIMEQQ (*timedate*,*iyr*,*imon*,*iday*,*ihr*,*imin*,*isec*)

timedate	(Output) INTEGER(4). Packed time and date information.
iyr	(Input) INTEGER(2). Year (*xxxx*AD).

imon	(Input) INTEGER(2). Month (1 - 12).
iday	(Input) INTEGER(2). Day (1 - 31)
ihr	(Input) INTEGER(2). Hour (0 - 23)
imin	(Input) INTEGER(2). Minute (0 - 59)
isec	(Input) INTEGER(2). Second (0 - 59)

The input values are interpreted as being in the time zone set on the local computer and following the daylight savings rules for that time zone.

The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

Example

```
USE IFPORT
INTEGER(2) year, month, day, hour, minute, second,   &
           hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour,   &
                 minute, second)
END
```

PARALLEL Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Defines a parallel region.*

Syntax

```
!$OMP PARALLEL [clause[[,] clause] ... ]
   loosely-structured-block
!$OMP END PARALLEL
-or-
!$OMP PARALLEL [clause[[,] clause] ... ]
   strictly-structured-block
[!$OMP END PARALLEL]
```

clause — Is one or more of the following:

- ALLOCATE ([allocator :] list)
- COPYIN (list)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)

- FIRSTPRIVATE (list)
- IF ([PARALLEL:] scalar-logical-expression)
- NUM_THREADS (*scalar_integer_expression*)

  Specifies the number of threads to be used in a parallel region. The *scalar_integer_expression* must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive.
- PRIVATE (list)
- PROC_BIND (PRIMARY | MASTER | CLOSE | SPREAD)

  Specifies a method for mapping the threads in the team to the "places" in the current partition.

  Once a thread is assigned to a place, the OpenMP* implementation should not move it to another place.

  PRIMARY instructs the execution environment to assign every thread in the team to the same place as the primary thread. MASTER has been deprecated and replaced by PRIMARY. CLOSE instructs the execution environment to assign the threads to places close to the place of the parent thread. SPREAD creates a sparse distribution for a team of T threads among the P places of the parent's place partition.

  For CLOSE and SPREAD, the threads with the smallest numbers are assigned starting with the place of the primary thread. For CLOSE, threads are packed into consecutive places within the parent's partition. For SPREAD, the partition of the primary thread is sub-divided and threads in the team are assigned round-robin to those subpartitions.

  Only a single PROC_BIND clause can appear in the directive.
- REDUCTION ([reduction-modifier,]reduction-identifier : list)
- SHARED (list)

loosely-structured-block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The PARALLEL and END PARALLEL directive pair must appear in the same routine in the executable section of the code.

The END PARALLEL directive denotes the end of the parallel region. There is an implied barrier at this point. Only the primary thread of the team continues execution at the end of a parallel region.

The number of threads in the team can be controlled by the NUM_THREADS clause, the environment variable OMP_NUM_THREADS, or by calling the runtime library routine OMP_SET_NUM_THREADS from a serial portion of the program.

NUM_THREADS supersedes the OMP_SET_NUM_THREADS routine, which supersedes the OMP_NUM_THREADS environment variable. Subsequent parallel regions, however, are not affected unless they have their own NUM_THREADS clauses.

Once specified, the number of threads in the team remains constant for the duration of that parallel region.

If the dynamic threads mechanism is enabled by an environment variable or a library routine, then the number of threads requested by the NUM_THREADS clause is the maximum number to use in the parallel region.

The code contained within the dynamic extent of the parallel region is executed on each thread, and the code path can be different for different threads.

If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes the primary thread of that new team. By default, nested parallel regions are always serialized and executed by a team of one thread.

A variable with LOCAL_INIT or SHARED locality in a DO CONCURRENT statement associated with a LOOP directive that binds to the parallel region of this construct cannot appear in a PRIVATE or FIRST_PRIVATE clause in the PARALLEL directive.

Example

You can use the PARALLEL directive in coarse-grain parallel programs. In the following example, each thread in the parallel region decides what part of the global array X upon which to work based on the thread number:

```
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,NPOINTS)
      IAM = OMP_GET_THREAD_NUM( )
      NP = OMP_GET_NUM_THREADS( )
      IPOINTS = NPOINTS/NP
      CALL SUBDOMAIN(X,IAM,IPOINTS)
!$OMP END PARALLEL
```

Assuming you previously used the environment variable OMP_NUM_THREADS to set the number of threads to six, you can change the number of threads between parallel regions as follows:

```
      CALL OMP_SET_NUM_THREADS(3)
!$OMP PARALLEL
...
!$OMP END PARALLEL
      CALL OMP_SET_NUM_THREADS(4)
!$OMP PARALLEL DO
...
!$OMP END PARALLEL DO
```

PARALLEL and NOPARALLEL General Directives

General Compiler Directives: *PARALLEL facilitates auto-parallelization by assisting the compiler's dependence analysis of the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.*
This feature is only available for ifort.

Syntax

```
!DIR$ PARALLEL [clause[[,] clause] ... ]
!DIR$ NOPARALLEL
```

clause — Is one or more of the following:

- ALWAYS [ASSERT]

- FIRSTPRIVATE (*list*)

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different iterations are initialized to the value the variable had upon entering the parallel loop.
- LASTPRIVATE (*list*)

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel loop is exited, each variable has the value that resulted from the sequentially last iteration of the parallel loop.
- NUM_THREADS (*scalar_integer_expression*)

  Specifies the number of threads to be used to parallelize the immediately following DO loop. The *scalar_integer_expression* must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive. Once specified, the number of threads used remains constant for the duration of that parallelized DO loop.
- PRIVATE (*list*)

  Declares specified variables to be private to each thread in a team. The declared variables become private to a task.

list — Is one or more items in the form: var [:expr]…. Each list item must be separated by a comma.

var — Is a scalar or array variable. The following rules apply:

- Assumed-size arrays cannot appear in a PRIVATE clause.
- A variable that is part of another variable (for example, as an array or structure element) cannot appear in a PRIVATE clause.
- A variable that appears in a PRIVATE clause must either be definable, or an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
- Variables that appear in namelist statements, in variable format expressions, and in expressions for statement function definitions, cannot appear in a PRIVATE clause.

expr — Is an integer expression denoting the number of array elements to privatize. When *expr* is specified, *var* must be an array or a pointer variable. The following rules also apply:

- If *var* is an array, then only its first *expr* elements are privatized. If *expr* is omitted, the entire array is privatized.
- If *var* is a pointer, then the first *expr* elements are privatized (element size is provided by the pointer's target type). If *expr* is omitted, only the pointer variable itself is privatized.
- Program behavior is undefined if *expr* evaluates to a non-positive value, or if it exceeds the array size.

PARALLEL helps the compiler to resolve dependencies, facilitating auto-parallelization of the immediately following DO loop. It instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the loop. However, if dependencies are proven, they are not ignored.

In addition, PARALLEL ALWAYS overrides the compiler heuristics that estimate the likelihood that parallelization of a loop will increase performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

NOPARALLEL prevents auto-parallelization of the immediately following DO loop.

These directives take effect only if you specify the compiler option that enables auto-parallelization.

Caution
The directive PARALLEL ALWAYS should be used with care. Overriding the heuristics of the compiler should only be done if you are absolutely sure the parallelization will improve performance.

Example

```
program main
parameter (n=100)
integer x(n), a(n), k
!DIR$ NOPARALLEL
   do i=1,n
     x(i) = i
   enddo
!DIR$ PARALLEL LASTPRIVATE (k)
   do i=1,n
     a( x(i) ) = i
     k = x(i)
   enddo
   print *, k     ! print 100, the value of x(n)
end
```

PARALLEL DO

OpenMP* Fortran Compiler Directive: *Provides an abbreviated way to specify a parallel region containing a single DO directive.*

Syntax

```
!$OMP PARALLEL DO [clause[[,] clause] ... ]
      do-loop
[!$OMP END PARALLEL DO]
```

clause	Can be any of the clauses accepted by the DO or PARALLEL directives.
do-loop	Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. You cannot branch out of a DO loop associated with a DO directive.

If the END PARALLEL DO directive is not specified, the PARALLEL DO is assumed to end with the DO loop that immediately follows the PARALLEL DO directive. If used, the END PARALLEL DO directive must appear immediately after the end of the DO loop.

The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a DO directive.

Example

In the following example, the loop iteration variable is private by default and it is not necessary to explicitly declare it. The END PARALLEL DO directive is optional:

```
!$OMP PARALLEL DO
      DO I=1,N
          B(I) = (A(I) + A(I-1)) / 2.0
      END DO
!$OMP END PARALLEL DO
```

The following example shows how to use the REDUCTION clause in a PARALLEL DO directive:

```
!$OMP PARALLEL DO DEFAULT(PRIVATE) REDUCTION(+: A,B)
      DO I=1,N
        CALL WORK(ALOCAL,BLOCAL)
        A = A + ALOCAL
        B = B + BLOCAL
      END DO
!$OMP END PARALLEL DO
```

Syntax Rules for Compiler Directives

PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: *Specifies a PARALLEL construct that contains one DO SIMD construct and no other statement.*

Syntax

```
!$OMP PARALLEL DO SIMD [clause[[,] clause] ... ]
      do-loop
[!$OMP END PARALLEL DO SIMD]
```

clause

Can be any of the clauses accepted by the PARALLEL, DO, or SIMD directives.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END PARALLEL DO SIMD directive is not specified, an END PARALLEL DO SIMD directive is assumed at the end of *do-loop*.

You cannot specify NOWAIT in a PARALLEL DO SIMD directive.

Syntax Rules for Compiler Directives

PARALLEL LOOP

OpenMP* Fortran Compiler Directive: *Specifies a shortcut for indicating that a loop or loop nest can execute concurrently across multiple threads. This feature is only available for ifx.*

Syntax

```
!$OMP PARALLEL LOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END PARALLEL LOOP]
```

clause — Can be any of the clauses accepted by the PARALLEL or LOOP directives with identical meanings and restrictions.

do-loop — Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer.

The loop can be a DO CONCURRENT loop, subject to the rules specified for variables referenced in a DO CONCURRENT loop associated with LOOP and PARALLEL constructs.

This combined directive is semantically equivalent to a LOOP construct that immediately follows a PARALLEL directive. All restrictions for PARALLEL and LOOP constructs apply to this combined construct.

If used, the END PARALLEL LOOP directive must appear immediately after the end of the loop. If you do not specify an END PARALLEL LOOP directive, an END PARALLEL LOOP directive is assumed at the end of the *do-loop*.

PARALLEL construct
LOOP construct

PARALLEL MASKED

OpenMP* Fortran Compiler Directive: *Creates a PARALLEL construct containing a MASKED construct, with no Fortran statements in the PARALLEL construct which are not also in the MASKED construct. This feature is only available for ifx.*

Syntax

```
!$OMP PARALLEL MASKED [clause[[,] clause]... ]
```

```
   loosely-structured-block
!$OMP END PARALLEL MASKED
-or-
!$OMP PARALLEL MASKED [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END PARALLEL MASKED]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASKED directives with identical meanings and restrictions.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASKED construct nested inside of it. The semantics are identical to a MASKED construct specified immediately after a PARALLEL construct; the only Fortran statements in the construct are inside the *block*.

All restrictions for PARALLEL and MASKED constructs apply to this combined construct.

PARALLEL MASKED TASKLOOP

OpenMP* Fortran Compiler Directive: *Creates a PARALLEL construct containing a MASKED TASKLOOP construct, with no Fortran statements in the PARALLEL construct that are not also in the MASKED TASKLOOP construct. This feature is only available for ifx.*

Syntax

```
!$OMP PARALLEL MASKED TASKLOOP [clause[[,] clause]... ]
   loop-nest
[!$OMP END PARALLEL MASKED TASKLOOP]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASKED TASKLOOP directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASKED TASKLOOP construct nested inside of it. The semantics are identical to a MASKED TASKLOOP construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASKED TASKLOOP constructs apply to this combined construct.

PARALLEL MASKED TASKLOOP SIMD

OpenMP* Fortran Compiler Directive: *Creates a PARALLEL construct containing a MASKED TASKLOOP SIMD construct, with no Fortran statements in the PARALLEL construct that are not also in the MASKED TASKLOOP SIMD construct. This feature is only available for ifx.*

Syntax

```
!$OMP PARALLEL MASKED TASKLOOP SIMD [clause[[,] clause]... ]
   loop-nest
[!$OMP END PARALLEL MASKED TASKLOOP SIMD]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASKED TASKLOOP SIMD directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASKED TASKLOOP SIMD construct nested inside of it. The semantics are identical to a MASKED TASKLOOP SIMD construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASKED TASKLOOP SIMD constructs apply to this combined construct.

PARALLEL MASTER

OpenMP* Fortran Compiler Directive:
(Deprecated; see PARALLEL MASKED) Creates a PARALLEL construct containing a MASTER construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER construct. This feature is only available for ifx.

Syntax

```
!$OMP PARALLEL MASTER [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END PARALLEL MASTER
-or-
!$OMP PARALLEL MASTER [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END PARALLEL MASTER]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASTER directives with identical meanings and restrictions.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER construct nested inside of it. The semantics are identical to a MASTER construct specified immediately after a PARALLEL construct; the only Fortran statements in the construct are inside block.

All restrictions for PARALLEL and MASTER constructs apply to this combined construct.

The PARALLEL MASTER directive is deprecated; you should use the PARALLEL MASKED directive.

PARALLEL MASTER TASKLOOP

OpenMP* Fortran Compiler Directive:
(Deprecated, replaced by PARALLEL MASKED TASKLOOP) Creates a PARALLEL construct containing a MASTER TASKLOOP construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER TASKLOOP construct. This feature is only available for ifx.

Syntax

```
!$OMP PARALLEL MASTER TASKLOOP [clause[[,] clause]... ]
   loop-nest
[!$OMP END PARALLEL MASTER TASKLOOP]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASTER TASKLOOP directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER TASKLOOP construct nested inside of it. The semantics are identical to a MASTER TASKLOOP construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASTER TASKLOOP constructs apply to this combined construct.

The PARALLEL MASTER TASKLOOP directive is deprecated; you should use the PARALLEL MASKED TASKLOOP directive.

See Also

OpenMP Fortran Compiler Directives

PARALLEL directive
MASTER TASKLOOP directive

To learn more about canonical form loops, see the OpenMP* specification.

PARALLEL MASTER TASKLOOP SIMD

OpenMP* Fortran Compiler Directive: *(Deprecated, replaced by PARALLEL MASKED TASKLOOP SIMD) Creates a PARALLEL construct containing a MASTER TASKLOOP SIMD construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER TASKLOOP SIMD construct. This feature is only available for ifx.*

Syntax

```
!$OMP PARALLEL MASTER TASKLOOP SIMD [clause[[,] clause]... ]
   loop-nest
[!$OMP END PARALLEL MASTER TASKLOOP SIMD]
```

clause	Can be any of the clauses accepted by the PARALLEL or MASTER TASKLOOP SIMD directives with identical meanings and restrictions.
loop-nest	Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER TASKLOOP SIMD construct nested inside of it. The semantics are identical to a MASTER TASKLOOP SIMD construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASTER TASKLOOP SIMD constructs apply to this combined construct.

The PARALLEL MASTER TASKLOOP SIMD directive is deprecated; you should use the PARALLEL MASKED TASKLOOP SIMD directive.

To learn more about canonical form loops, see the OpenMP* specification.

PARALLEL SECTIONS

OpenMP* Fortran Compiler Directive: *Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.*

Syntax

```
!$OMP PARALLEL SECTIONS [clause[[,] clause] ...]
[!$OMP SECTION]
   block
[!$OMP SECTION
   block]...
!$OMP END PARALLEL SECTIONS
```

clause	Can be any of the clauses accepted by the PARALLEL or SECTIONS directives.

block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The last section ends at the END PARALLEL SECTIONS directive.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```
!$OMP PARALLEL SECTIONS
!$OMP SECTION
      CALL XAXIS
!$OMP SECTION
      CALL YAXIS
!$OMP SECTION
      CALL ZAXIS
!$OMP END PARALLEL SECTIONS
```

See Also

OpenMP Fortran Compiler Directives

PARALLEL WORKSHARE

OpenMP* Fortran Compiler Directive: *Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.*

Syntax

```
!$OMP PARALLEL WORKSHARE [clause[[,] clause] ... ]
   loosely-structured-block
!$OMP END PARALLEL WORKSHARE
-or-
!$OMP PARALLEL WORKSHARE [clause[[,] clause] ... ]
   strictly-structured-block
[!$OMP END PARALLEL WORKSHARE]
```

clause	Can be any of the clauses accepted by the PARALLEL directive.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARAMETER

Statement and Attribute: *Defines a named constant.*

Syntax

The PARAMETER attribute can be specified in a type declaration statement or a PARAMETER statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] PARAMETER [, *att-ls*] :: *c* =*expr*[, *c* = *expr*] ...

Statement:

PARAMETER [( ]*c*= *expr*[, *c*= *expr*] ... [)]

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
c	Is the name of the constant.
expr	Is a constant expression. It can be of any data type.

Description

The type, type parameters, and shape of the named constant are determined in one of the following ways:

- By an explicit type declaration statement in the same scoping unit.
- By the implicit typing rules in effect for the scoping unit. If the named constant is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

For example, consider the following statement:

```
PARAMETER (MU=1.23)
```

According to implicit typing, MU is of integer type, so MU=1. For MU to equal 1.23, it should previously be declared REAL in a type declaration or be declared in an IMPLICIT statement.

A named array constant defined by a PARAMETER statement must have its rank specified in a previous specification statement.

A named constant must not appear in a format specification or as the character count for Hollerith constants. For compilation purposes, writing the name is the same as writing the value.

If the named constant is used as the length specifier in a CHARACTER declaration, it must be enclosed in parentheses.

The name of a constant cannot appear as part of another constant, although it can appear as either the real or imaginary part of a complex constant.

You can only use the named constant within the scoping unit containing the defining PARAMETER statement.

Any named constant that appears in the constant expression must have been defined previously in the same type declaration statement (or in a previous type declaration statement or PARAMETER statement), or made accessible by use or host association.

An entity with the PARAMETER attribute must not be a variable, a coarray, or a procedure.

Omission of the parentheses in a PARAMETER statement is an extension controlled by compiler option `altparam`. In this form, the type of the name is taken from the form of the constant rather than from implicit or explicit typing of the name.

Example

The following example shows a type declaration statement specifying the PARAMETER attribute:

```
REAL, PARAMETER :: C = 2.9979251, Y = (4.1 / 3.0)
```

The following is an example of the PARAMETER statement:

```
 REAL(4) PI, PIOV2
 REAL(8) DPI, DPIOV2
 LOGICAL FLAG
 CHARACTER*(*) LONGNAME
 PARAMETER (PI=3.1415927, DPI=3.141592653589793238D0)
 PARAMETER (PIOV2=PI/2, DPIOV2=DPI/2)
 PARAMETER (FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS')
```

The following shows implicit-shape arrays declared using a PARAMETER attribute and PARAMETER statements:

```
 INTEGER, PARAMETER :: R(*) = [1,2,3]
 REAL :: M (2:*, -1:*)
 PARAMETER (M = RESHAPE ([R,R], [3,2]))
```

The following shows other examples:

```
! implicit integer type
PARAMETER (nblocks = 10)
!
! implicit real type
IMPLICIT REAL (L-M)
PARAMETER (loads = 10.0, mass = 32.2)
!
! typed by PARAMETER statement
! Requires compiler option
PARAMETER mass = 47.3, pi = 3.14159
PARAMETER bigone = 'This constant is larger than forty characters'
!
! PARAMETER in attribute syntax
REAL, PARAMETER :: mass=47.3, pi=3.14159, loads=10.0, mass=32.2
```

PARITY

Transformational Intrinsic Function (Generic):
Reduces an array by using an exclusive OR (.NEQV.) operation.

Syntax

`result = PARITY (mask)`

`result = PARITY (mask, dim)`

mask	(Input) Must be an array of type logical.
dim	(Input) Must be a scalar integer with a value in the range 1 <= *dim* <= *n*, where *n* is the rank of *mask*.

Results

The result has the same type and kind parameters as *mask*. It is scalar if *dim* is not specified; otherwise, the result has rank *n* - 1 and shape [d_1, d_2, ..., d_{dim-1}, d_{dim+1} , ..., d_n] where [d_1, d_2,..., d_n] is the shape of *mask*.

The result of PARITY(*mask*) has the value .TRUE. if an odd number of the elements of mask are true; otherwise, .FALSE..

If *mask* has rank one, PARITY(*mask*, *dim*) is equal to PARITY(*mask*). Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1} , ..., s_n) of PARITY(*mask*, *dim*) is equal to PARITY (*mask* (s_1, s_2, ..., s_{dim-1} , :, s_{dim+1} , ..., s_n)).

Example

If A is the array

```
  [ T  F  T ]
  [ T  T  F ]
```

and T has the value .TRUE. and F has the value .FALSE., then

PARITY (A, DIM=1) has the value [F, T, T] and PARITY (A, DIM=2) has the value [F, F].

PAUSE

Statement: *Temporarily suspends program execution and lets you execute operating system commands during the suspension. The PAUSE statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.*

Syntax

```
PAUSE [pause-code]
```

pause-code — (Optional) Is an optional message. It can be either of the following:

- A scalar character constant of type default character.
- A string of up to six digits; leading zeros are ignored. (Standard Fortran limits digits to five.)

If you specify *pause-code*, the PAUSE statement displays the specified message and then displays the default prompt.

If you do not specify *pause-code*, the system displays the following default message:

```
    FORTRAN PAUSE
```

The following prompt is then displayed:

- On Windows* systems:

```
Fortran Pause - Enter command<CR> or <CR> to continue.
```

- On Linux* systems:

```
PAUSE prompt>
```

For alternate methods of pausing while reading from and writing to a device, see READ and WRITE.

Effect on Windows* Systems

The program waits for input on `stdin`. If you enter a blank line, execution resumes at the next executable statement.

Anything else is treated as a DOS command and is executed by a system( ) call. The program loops, letting you execute multiple DOS commands, until a blank line is entered. Execution then resumes at the next executable statement.

Effect on Linux* Systems

The effect of PAUSE differs depending on whether the program is a foreground or background process, as follows:

- If a program is a foreground process, the program is suspended until you enter the CONTINUE command. Execution then resumes at the next executable statement.

  Any other command terminates execution.
- If a program is a background process, the behavior depends on `stdin`, as follows:
  - If `stdin`is redirected from a file, the system displays the following (after the pause code and prompt):

```
To continue from background, execute 'kill -15 n'
```

    In this message, `n`is the process id of the program.
  - If `stdin`is not redirected from a file, the program becomes a suspended background job, and you must specify `fg`to bring the job into the foreground. You can then enter a command to resume or terminate processing.

Example

The following examples show valid PAUSE statements:

```
 PAUSE 701
 PAUSE 'ERRONEOUS RESULT DETECTED'
```

The following shows another example:

```
 CHARACTER*24 filename
 PAUSE 'Enter DIR to see available files or press RETURN'   &
&' if you already know filename.'
 READ(*,'(A\)') filename
 OPEN(1, FILE=filename)
 . . .
```

Deleted and Obsolescent Language Features

PEEKCHARQQ

Runtime Function: *Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.*

Module

USE IFCORE

Syntax

```
result = PEEKCHARQQ( )
```

Results

The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..

To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ to .FALSE..

Example

```
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
  WRITE(*,*) ' Press any key'
  pressed = PEEKCHARQQ ( )
END DO
END
```

GETC

PERROR

Runtime Subroutine: *Sends a message to the standard error stream, preceded by a specified string, for the last detected error.*

Module

USE IFCORE

Syntax

CALL PERROR (*string*)

string	(Input) Character*(*). Message to precede the standard error message.

The string sent is the same as that given by GERROR.

Example

```
USE IFCORE
character*24 errtext
errtext = 'In my opinion, '
. . .
! any error message generated by errtext is
!    preceded by 'In my opinion, '
Call PERROR (errtext)
```

POINTER - Fortran

Statement and Attribute: *Specifies that an object or a procedure is a pointer (a dynamic variable). A pointer does not contain data, but points to a scalar or*

array variable where data is stored. A pointer has no initial storage set aside for it; memory storage is created for the pointer as a program runs.

Syntax

The POINTER attribute can be specified in a type declaration statement or a POINTER statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] POINTER [, *att-ls*] :: *ptr*[(*d-spec*)][, *ptr*[(*d-spec*)]]...

Statement:

POINTER [::]*ptr*[(*d-spec*)][, *ptr*[(*d-spec*)]] ...

type-spec	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
ptr	Is the name of the pointer. The pointer cannot be declared with the INTENT or PARAMETER attributes.
d-spec	(Optional) Is a deferred-shape specification (: [, :] ...). Each colon represents a dimension of the array.

Description

No storage space is created for a data pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target.

Each pointer has an association status, which tells whether the pointer is currently associated with a target object. When a pointer is initially declared, its status is undefined. You can use the ASSOCIATED intrinsic function to find the association status of a pointer if the pointer's association status is defined.

Entities with the POINTER attribute can be associated with different data objects or procedures during execution of a program.

A data pointer must not be referenced or defined unless it is pointer associated with a target object that can be referenced or defined. A procedure pointer must not be referenced unless it is pointer associated with a target procedure.

If the data pointer is an array, and it is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

A pointer cannot be specified in an EQUIVALENCE or NAMELIST statement. A pointer in a DATA statement can only be associated with NULL().

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

An entity with the POINTER attribute must not have the ALLOCATABLE, INTRINSIC, or TARGET attribute, and it must not be a coarray.

Fortran pointers are *not* the same as integer pointers. For more information, see the POINTER - Integer statement.

Example

The following example shows type declaration statements specifying the POINTER attribute:

```
TYPE(SYSTEM), POINTER :: CURRENT, LAST
REAL, DIMENSION(:,:), POINTER :: I, J, REVERSE
```

The following is an example of the POINTER statement:

```
TYPE(SYSTEM) :: TODAYS
POINTER :: TODAYS, A(:,:)
```

The following shows another example:

```
REAL, POINTER :: arrow (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:,:)

! The following statement associates the pointer with an unused
! block of memory.

ALLOCATE (arrow (1:8), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(/1x,a)') 'ARROW allocated'
arrow = 5.
WRITE (*,'(1x,8f8.0/)') arrow
ALLOCATE (bullseye (1:8,3), STAT = ierr)
IF (ierr.eq.0) WRITE (*,*) 'BULLSEYE allocated'
bullseye = 1.
bullseye (1:8:2,2) = 10.
WRITE (*,'(1x,8f8.0)') bullseye

! The following association breaks the association with the first
! target, which being unnamed and unassociated with other pointers,
! becomes lost. ARROW acquires a new shape.

arrow => bullseye (2:7,2)
WRITE (*,'(/1x,a)') 'ARROW is repointed & resized, all the 5s are lost'
WRITE (*,'(1x,8f8.0)') arrow

NULLIFY (arrow)
IF (.NOT.ASSOCIATED(arrow)) WRITE (*,'(/a/)') ' ARROW is not pointed'

DEALLOCATE (bullseye, STAT = ierr)
IF (ierr.eq.0) WRITE (*,*) 'Deallocation successful.'
END
```

POINTER - Integer

Statement: *Establishes pairs of objects and pointers, in which each pointer contains the address of its paired object. This statement is different from the Fortran POINTER statement.*

Syntax

```
POINTER (pointer,pointee) [,(pointer,pointee)] . . .
```

pointer	Is a variable whose value is used as the address of the *pointee*.
pointee	Is a variable; it can be an array name or array specification. It can also be a procedure named in an EXTERNAL statement or in a specific (non-generic) procedure interface block.

The following are *pointer* rules and behavior:

- Two pointers can have the same value, so pointer aliasing is allowed.
- When used directly, a pointer is treated like an integer variable. On IA-32 architecture, a pointer occupies one numeric storage unit, so it is a 32-bit quantity (INTEGER(4)). On Intel® 64 architecture, a pointer occupies two numeric storage units, so it is a 64-bit quantity (INTEGER(8)).
- A pointer cannot be a pointee.
- A pointer cannot appear in an ASSIGN statement and cannot have the following attributes:

ALLOCATABLE	INTRINSIC	POINTER
EXTERNAL	PARAMETER	TARGET

  A pointer can appear in a DATA statement with integer literals only.
- Integers can be converted to pointers, so you can point to absolute memory locations.
- A pointer variable cannot be declared to have any other data type.
- A pointer cannot be a function return value.
- You can give values to pointers by doing the following:
  - Retrieve addresses by using the LOC intrinsic function (or the %LOC built-in function).
  - Allocate storage for an object by using the MALLOC intrinsic function (or by using malloc(3f) on Linux* systems).

  For example:

```
Using %LOC:                 Using MALLOC:

INTEGER I(10)               INTEGER I(10)
INTEGER I1(10) /10*10/      POINTER (P,I)
POINTER (P,I)               P = MALLOC(40)
P = %LOC(I1)                I = 10
I(2) = I(2) + 1             I(2) = I(2) + 1
```

- The value in a pointer is used as the pointee's base address.

The following are *pointee* rules and behavior:

- A pointee is not allocated any storage. References to a pointee look to the current contents of its associated pointer to find the pointee's base address.
- A pointee cannot be data-initialized or have a record structure that contains data-initialized fields.
- A pointee can appear in only one integer POINTER statement.
- A pointee array can have fixed, adjustable, or assumed dimensions.
- A pointee cannot appear in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement, and it cannot have the following attributes:

ALLOCATABLE	OPTIONAL	SAVE

AUTOMATIC	PARAMETER	STATIC
INTENT	POINTER	

- A pointee cannot be:
  - A dummy argument
  - A function return value
  - A record field or an array element
  - Zero-sized
  - An automatic object
  - The name of a generic interface block
- If a pointee is of derived type, it must be of sequence type.

Example

```
POINTER (p, k)
INTEGER j(2)

! This has the same effect as j(1) = 0, j(2) = 5
p = LOC(j)
k = 0
p = p + SIZEOF(k) ! 4 for 4-byte integer
k = 5
```

POPCNT

Elemental Intrinsic Function (Generic): *Returns the number of 1 bits in the integer argument.*

Syntax

`result = POPCNT (i)`

i	(Input) Must be of type integer or logical.

Results

The result type and kind are the same as *i*. The result value is the number of 1 bits in the binary representation of the integer *i*.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

If the value of I is B'0...00011010110', the value of POPCNT(I) is 5.

POPPAR

Elemental Intrinsic Function (Generic): *Returns the parity of the integer argument.*

Syntax

`result = POPPAR (i)`

i	(Input) Must be of type integer or logical.

Results

The result type and kind are the same as *i*. The result value is 1 if there are an odd number of 1 bits in the binary representation of the integer I. The result value is zero if there are an even number.

POPPAR(*i*) is the same as 1 .AND. POPCNT(*i*).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

If the value of I is B'0...00011010110', the value of POPPAR(I) is 1.

PRECISION

Inquiry Intrinsic Function (Generic): *Returns the decimal precision in the model representing real numbers with the same kind parameter as the argument.*

Syntax

```
result = PRECISION (x)
```

x	(Input) Must be of type real or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer. The result has the value INT((DIGITS(*x*) - 1) * LOG10(RADIX(*x*))). If RADIX(*x*) is an integral power of 10, 1 is added to the result.

Example

If X is a REAL(4) value, PRECISION(X) has the value 6. The value 6 is derived from INT ((24-1) * LOG10 (2.)) = INT (6.92...). For more information on the model for REAL(4), see Model for Real Data.

PREFETCH and NOPREFETCH General Directives

General Compiler Directives: *PREFETCH hints to the compiler to prefetch data into closer levels of cache. Prefetching data can minimize the effects of memory latency. NOPREFETCH disables data prefetching. These directives give fine-level control to the programmer to influence the prefetches generated by the compiler.*

Syntax

```
!DIR$ PREFETCH [var1[: hint1[: distance1]] [,var2[: hint2[: distance2]]]...]
!DIR$ PREFETCH *: hint[: distance]
!DIR$ NOPREFETCH [var1[,var2]...]
```

var	Is an optional memory reference.

hint	Is an optional integer constant expression with the integer value 0, 1, 2, or 3. These are the same as the defined values FOR_K_PREFETCH_T0, FOR_K_PREFETCH_T1, FOR_K_PREFETCH_T2, or FOR_K_PREFETCH_NTA for *hint* in the intrinsic subroutine MM_PREFETCH. To use this argument, you must also specify *var*.
distance	Is an optional integer constant expression with a value greater than 0. It indicates the number of (possibly vectorized) loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify *var* and *hint*.

To use these directives, compiler option `[q or Q]opt-prefetch` must be set. Note that this option is turned on by default if the compiler general optimization level is O2 or higher.

This directive affects the DO loop it precedes.

If you specify PREFETCH *, the *hint* and optional *distance* are used to prefetch all array accesses in the DO loop.

If you specify NOPREFETCH with no arguments, the following occurs:

- All arrays accessed in the DO loop will NOT be prefetched.
- It negates all other PREFETCH directives for the following DO loop.

If a loop includes expression A(j), placing !DIR$ PREFETCH A:0:d in front of the loop instructs the compiler to insert a vprefetch0 instruction for A within the loop that is d iterations ahead.

The PREFETCH directive takes precedence over the `[q or Q]opt-prefetch-distance` options.

The variables in a NOPREFETCH or PREFETCH directive take precedence over PREFETCH *.

A NOPREFETCH directive with no arguments negates all other PREFETCH directives for the following DO loop.

Example

```
! Issue no prefetches for A1
! Issue vector prefetch from L2 and higher caches for B with a distance
!   of 16 vectorized iterations ahead
! Issue vector prefetch from L1 and higher caches for B with a distance
!   of 4 vectorized iterations ahead
!DIR$ NOPREFETCH A1
!DIR$ PREFETCH B:1:16
!DIR$ PREFETCH B:0:4
   DO J = 1,N
      A1(J) = B(J-1) + B(J+1)
   END DO
```

In the following example, array A will be prefetched with hint 0 and distance 5, arrays B and C will be prefetched with hint 1 and distance 10, and array D will not be prefetched:

```
!DIR$ PREFETCH *:1:10
!DIR$ PREFETCH A:0:5
!DIR$ NOPREFETCH D
    DO J = 1, N
       A (J) = B (J) + C (J) + D (J)
    END DO
```

PREFETCH DATA Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Suggests to the compiler to preload data into cache. Preloading data in cache minimizes the effects of memory latency. This feature is only available for ifx.*

Syntax

```
!$OMPX PREFETCH DATA([prefetch-hint-modifier:] array-section [, array-section] ...)
[clause]
```

prefetch-hint-modifier — Is an positive integer literal constant whose value is between 0 and 7, inclusive. If not specified, the default value is 0. The values indicate the following:

- 0: no-op
- 1: L1 uncached and L3 uncached
- 2: L1 uncached and L3 chached
- 3: l1 cached and L3 uncached
- 4: L1 cached and L3 cached
- 5: L1 streaming load and L3 uncached
- 6: L1 streaming load and L3 cached
- 7: L1 invalidate-after-read and L3 cached

array-section — Is a contiguous array section (stride value is either 1 or not specified).

clause — Is the following:

IF (scalar-logical-expression)

Description

The PREFETCH DATA directive issues a prefetch to preload the data specified by *array-section*. If the IF clause is present, the prefetch is done only when the *scalar-logical-expression* evaluates to .TRUE..

The PREFETCH DATA directive is a pure directive, so it can appear in a Fortran PURE procedure.

Example

The following code prefetches and caches elements 17 thru 1024 of the arrays y and z to L1 and L3 cache. Each element is prefetched 16 iterations prior to its use in the computation y(i) + z(i).

```
SUBROUTINE sub ()
  IMPLICIT NONE
  REAL,DIMENSION(1024)    :: y, x, z
  INTEGER                 :: i
  . . .
  DO m = 1, 1024
   !$ompx  PREFETCH DATA (4: y(i+16), z(i+16)) &
    !$ompx& IF ((MOD(i, 16) .eq. 1) .and. ((i+15 .le. 1024))
    x(i) = y(i) + z(i)
  END DO
  . . .
END SUBROUTINE
```

Syntax Rules for Compiler Directives

PRESENT

Inquiry Intrinsic Function (Generic): *Returns whether or not an optional dummy argument is present, that is, whether it has an associated actual argument.*

Syntax

```
result = PRESENT (a)
```

a	(Input) Must be an argument of the current procedure and must have the OPTIONAL attribute. An explicit interface for the current procedure must be visible to its caller; for more information, see Procedure Interfaces.

Results

The result is a scalar of type default logical. The result is .TRUE. if *a* is present; otherwise, the result is .FALSE..

Example

Consider the following:

```
MODULE MYMOD
CONTAINS
SUBROUTINE CHECK (X, Y)
  REAL X, Z
  REAL, OPTIONAL :: Y
  ...
  IF (PRESENT (Y)) THEN
    Z = Y
  ELSE
     Z = X * 2
  END IF
END SUBROUTINE CHECK
END MODULE MYMOD
...
USE MYMOD
CALL CHECK (15.0, 12.0) ! Causes Z to be set to 12.0
CALL CHECK (15.0) ! Causes Z to be set to 30.0
```

The following shows another example:

```
 CALL who( 1, 2 ) ! prints "A present" "B present"
 CALL who( 1 ) ! prints "A present"
 CALL who( b = 2 ) ! prints "B present"
 CALL who( ) ! prints nothing
 CONTAINS
   SUBROUTINE who( a, b )
     INTEGER(4), OPTIONAL :: a, b
     IF (PRESENT(a)) PRINT *,'A present'
     IF (PRESENT(b)) PRINT *,'B present'
   END SUBROUTINE who
 END
```

See Also

OPTIONAL
Optional Arguments

PRINT

Statement: *Displays output on the screen. TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.*

Syntax

The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using environment variable FOR_PRINT.

A PRINT statement takes one of the following forms:

Formatted:

```
PRINT form[, io-list]
```

Formatted - List-Directed:

```
PRINT *[, io-list]
```

Formatted - Namelist:

```
PRINT nml
```

form	Is the nonkeyword form of a format specifier (no FMT=).
io-list	Is an I/O list.
*	Is the format specifier indicating list-directed formatting.
nml	Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

Example

In the following example, one record (containing four fields of data) is printed to the implicit output device:

```
      CHARACTER*16 NAME, JOB
      PRINT 400, NAME, JOB
400   FORMAT ('NAME=', A, 'JOB=', A)
```

The following shows another example:

```
!   The following statements are equivalent:
    PRINT     '(A11)', 'Abbottsford'
    WRITE (*, '(A11)') 'Abbottsford'
    TYPE      '(A11)', 'Abbottsford'
```

PRINT as a value in CLOSE

PRIORITY

Parallel Directive Clause: *Specifies that the generated tasks have the indicated priority for execution.*

Syntax

`PRIORITY (priority-value)`

priority-value	Provides a hint for the priority of task execution order. *priority-value* must evaluate to a non-negative scalar integer value.

Among all tasks ready to be executed, higher priority tasks (those with a higher numerical value of *priority-value*) are recommended to execute before lower priority tasks. A program that relies on task execution order being determined by this *priority-value* may have unspecified behavior.

At most one PRIORITY clause can appear in the directive.

If this clause is not specified, tasks generated by the construct have a task priority of zero (the default).

PRIVATE Clause

Parallel Directive Clause: *Declares one or more variables to be private to each thread in a team.*

Syntax

`PRIVATE (list)`

list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

This clause allows each thread to have its own copy of the variable and makes it a local variable to the thread.

The following occurs when variables are declared in a PRIVATE clause:

- A new object of the same type is declared once for each thread in the team (or for each implicit task in a region) and it is used by each thread (or task) inside the scope of the directive construct instead of the original variable. The new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
- Variables defined as PRIVATE are undefined for each thread upon entering the construct and the corresponding shared variable is undefined when the parallel construct is exited. Within a parallel, worksharing, or task region, the initial status of a private pointer is undefined.

The value and allocation status of the original variable will change only in the following cases:

- If it is accessed and modified by means of a pointer
- If it is accessed in the region but outside of the construct
- As a side effect of directives or clauses
- If accessed and modified via construct association.

If a variable has the ALLOCATABLE attribute, the following rules apply:

- If the variable is not currently allocated, the new list item will have an initial state of "unallocated".
- If the variable is allocated, the new list item will have an initial state of allocated with the same array bounds.

A variable that appears in a PRIVATE clause may be storage-associated with other variables when the PRIVATE clause is encountered by constructs such as EQUIVALENCE or COMMON. If A is a variable appearing in a PRIVATE clause and B is a variable that is storage-associated with A, then the following applies:

- The contents, allocation, and association status of B are undefined on entry to the parallel or task region.
- Any definition of A, or any definition of its allocation or association status, causes the contents, allocation, and association status of B to become undefined.
- Any definition of B, or any definition of its allocation or association status, causes the contents, allocation, and association status of A to become undefined.
- A list item that appears in a private clause can be a *selector* in an ASSOCIATE construct. If the ASSOCIATE construct association is established before entry to a parallel region, the association between the associate *name* and the original PRIVATE list item will be retained in the parallel region.

The following are restrictions for the PRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that appears in a PRIVATE clause must either be definable or it must be an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
- Assumed-size arrays must not appear in a PRIVATE clause.
- A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a PRIVATE clause. This restriction does not apply to the FIRSTPRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

Variables in a *list* can appear in other clauses as follows:

- Variables that appear in a PRIVATE, FIRSTPRIVATE, or REDUCTION clause in a parallel construct can also appear in a PRIVATE clause in an enclosed parallel, task, or worksharing construct.
- Variables that appear in a PRIVATE or FIRSTPRIVATE clause in a task construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.
- Variables that appear in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clause in a worksharing construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.

NOTE
Variables that are used as counters for explicit or implicit DO loops or FORALL commands, or common blocks that are specified to be THREADPRIVATE become automatically private to each thread, even though they are not explicitly included inside a PRIVATE clause at the beginning of the scope of the parallel region.

Example

Consider the following:

```
!$OMP PARALLEL PRIVATE(A, B)
```

In this simple case, each thread will have its own copy of variables A and B. The variables can have different values in each thread because the variables are local to the thread.

See Also

FIRSTPRIVATE clause
LASTPRIVATE clause

PRIVATE Statement

Statement and Attribute: *Specifies that entities in a module can be accessed only within the module itself.*

Syntax

The PRIVATE attribute can be specified in a type declaration statement or a PRIVATE statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] PRIVATE [, *att-ls*] :: *entity*[, *entity*]...

Statement:

PRIVATE [[::] *entity*[, *entity*] ...]

type — Is a data type specifier.

att-ls — Is an optional list of attribute specifiers.

entity — Is one of the following:

- A variable name
- A procedure name
- A derived type name
- A named constant
- A namelist group name
- An OpenMP* reduction-identifier

In statement form, an entity can also be one of the following:

- A module name
- A generic name
- A defined operator
- A defined assignment
- A defined I/O generic specification

Description

The PRIVATE attribute can only appear in the scoping unit of a module.

Only one PRIVATE statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by USE association whose names do not appear in a PUBLIC statement.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PRIVATE statement, the module name must have appeared in a USE statement within the same scoping unit.

A PRIVATE attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies the derived-type definition is not accessible outside the module or the module's descendants.

A PRIVATE statement without an entity-list can appear in the component-definition part of a derived-type definition, specifying the default accessibility of all components as PRIVATE. A PRIVATE statement with no entity-list can appear in the type-bound-procedure-part of a derived-type definition specifying the default accessibility of all type-bound procedures of that type as PRIVATE. In such cases, the default accessibility of components and type-bound procedures can be overridden by explicitly declaring a component or type-bound procedure PUBLIC.

A PRIVATE attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is not accessible outside the module or its descendants.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility. Entities with PUBLIC accessibility can be accessed from outside the module by means of a USE statement.

If a derived type is declared PRIVATE in a module, its components are also PRIVATE. The derived type and its components are accessible to any subprograms within the defining module and the module's descendants through host association, but they are not accessible from outside the module.

If the derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the definition.

Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```
REAL,  PRIVATE  :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
  PRIVATE RESTRICTED_DATA
END MODULE
```

The following derived-type declaration statement indicates that the type is restricted to the module:

```
TYPE, PRIVATE  :: DATA
  ...
END TYPE DATA
```

The following example shows a PUBLIC type with PRIVATE components:

```
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```
!LENGTH in module VECTRLEN calculates the length of a 2-D vector.
!The module contains both private and public procedures
   MODULE VECTRLEN
     PRIVATE SQUARE
     PUBLIC LENGTH
    CONTAINS
    SUBROUTINE LENGTH(x,y,z)
       REAL,INTENT(IN) x,y
       REAL,INTENT(OUT) z
       CALL SQUARE(x,y)
       z = SQRT(x + y)
       RETURN
    END SUBROUTINE
    SUBROUTINE SQUARE(x1,y1)
       REAL x1,y1
       x1 = x1**2
       y1 = y1**2
       RETURN
    END SUBROUTINE
   END MODULE
```

PROCEDURE

Statement: *Declares procedure pointers, dummy procedures, and external procedures.*

Syntax

`PROCEDURE ([`*proc-interface*`]) [[, `*proc-attr-spec*`]... :: ] `*proc-decl-list*

proc-interface

(Optional) Is the name of an interface, an intrinsic type specifier, or a derived-type TYPE statement.

If an interface name is specified, it must be the name of an abstract interface, a procedure that has an explicit interface, or a procedure pointer. It must have been previously declared and it cannot be the same as a keyword that specifies an intrinsic type.

If *proc-interface* is a type specifier, the declared procedures or procedure pointers are functions that have implicit interfaces and the specified result type. If a type is specified for an external function, its function definition must specify the same result type and type parameters.

If *proc-interface* is the interface of an elemental procedure, each procedure name must be an external procedure.

proc-attr-spec

(Optional) Is one of the following attributes:

- PUBLIC
- PRIVATE
- BIND (C [, NAME = *init-expr*])
  This is also called a *language-binding-spec*. The *init-expr* is a scalar character constant expression of default character kind. If NAME= is specified, there can only be one *proc-decl* item, which cannot have the POINTER attribute or be a dummy procedure.
- INTENT(INOUT)
- OPTIONAL
- POINTER
- PROTECTED
- SAVE

Each *proc-attr-spec* gives the corresponding attribute to all procedures declared in that statement.

If a procedure entity has the INTENT attribute or SAVE attribute, it must also have the POINTER attribute.

proc-decl-list

Is one or more of the following:

procedure-name [=> *null-init*]
where *null-init* is a reference to intrinsic function NULL with no arguments. If => *null-init* appears, the procedure must have the POINTER attribute. procedure-name is the name of a nonintrinsic procedure

Description

A PROCEDURE statement declares nonintrinsic procedures (procedure pointers, dummy procedures, internal procedures, and external procedures). If the procedure is not a procedure pointer, a module procedure, or an internal procedure, it specifies the EXTERNAL attribute for the procedure.

You cannot use the PROCEDURE statement to identify a BLOCK DATA subprogram.

If => *null-init* appears, it specifies that the initial association status of the corresponding procedure entity is disassociated. It also implies the SAVE attribute.

You can also declare procedures by using an EXTERNAL statement or a procedure component definition statement.

If the BIND attribute is specified for a procedure, each dummy argument must be:

- An interoperable procedure or a variable that is interoperable
- Assumed shape
- Assumed rank
- Assumed type
- Of assumed-character length or has the ALLOCATABLE or POINTER attribute

If the BIND attribute is specified for a function, the function result must be an interoperable scalar variable.

A Fortran procedure is interoperable if it has the BIND attribute; that is, if its interface is specified with a *language-binding-spec*.

The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a procedure that has a BIND attribute.

A dummy argument of a procedure that has a BIND attribute must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that has a BIND attribute must be of interoperable type or assumed type.

When a procedure whose interface has the BIND attribute is called, any actual argument corresponding to a dummy argument with the ALLOCATABLE or POINTER attribute is passed by C descriptor. Similarly, if a Fortran procedure with a BIND attribute has such dummy arguments, they are received by C descriptor.

Example

Consider the following:

```
PROCEDURE (NAME_TEMP) :: NAME37
```

The above declares `NAME37` to be a procedure with an identical interface to that of `NAME_TEMP`.

The following are equivalent:

```
PROCEDURE (INTEGER) X
INTEGER, EXTERNAL :: X
```

Consider the following:

```
ABSTRACT INTERFACE
  FUNCTION SIM_FUNC (X)
    REAL, INTENT (IN) :: X
    REAL :: SIM_FUNC
  END FUNCTION SIM_FUNC
END INTERFACE

INTERFACE
  SUBROUTINE SUB2 (X)
    REAL, INTENT (IN) :: X
  END SUBROUTINE SUB2
END INTERFACE
```

The following shows external and dummy procedures with explicit interfaces:

```
PROCEDURE (SIM_FUNC) :: VMAC, KAPPA
PROCEDURE (SUB2) :: PRINGLES
```

The following shows procedure pointers with an explicit interface, one initialized to NULL():

```
PROCEDURE (SIM_FUNC), POINTER :: P1, R1 => NULL()
PROCEDURE (SIM_FUNC), POINTER :: KAPPA_POINTER
```

The following shows a derived type with a procedure pointer component:

```
TYPE MEMO_TYPE
  PROCEDURE (SIM_FUNC), POINTER :: COMPONENT
END TYPE MEMO_TYPE
```

The following shows a variable of the above type:

```
TYPE (MEMO_TYPE) :: STRUCTA
```

The following shows an external or dummy function with an implicit interface:

```
PROCEDURE (INTEGER) :: PHIL0
```

PROCESSOR Clause

Parallel Directive Clause: *Tells the compiler to create a vector version of the routine for the specified processor. When running on a processor that does not match "cpuid", a scalar version will be invoked multiple times based on vector length.*

Syntax

`PROCESSOR (cpuid)`

cpuid

Is one of the following:

`atom`	Intel Atom® processors with Supplemental Streaming SIMD Extensions 3 (SSSE3)
`atom_sse4_2`	Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)
`atom_sse4_2_movbe`	Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) with MOVBE instructions enabled
`broadwell`	This is a synonym for `core_5th_gen_avx`.
`core_2_duo_sse4_1`	Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture processors with Intel® Streaming SIMD Extensions 4.1 (Intel® SSE4.1)
`core_2_duo_ssse3`	Intel® Core™2 Duo processors with Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)
`core_2nd_gen_avx`	2nd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX)

`core_3rd_gen_avx`	3rd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX) including the RDRND instruction
`core_4th_gen_avx`	4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction
`core_4th_gen_avx_tsx`	4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)
`core_5th_gen_avx`	5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions
`core_5th_gen_avx_tsx`	5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)
`core_aes_pclmulqdq`	Intel® Core™ processors with support for Advanced Encryption Standard (AES) instructions and carry-less multiplication instruction
`core_i7_sse4_2`	Intel® Core™ i7 processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) instructions
`generic`	Other Intel processors for IA-32 or Intel® 64 architecture or compatible processors not provided by Intel Corporation

`haswell`	This is a synonym for `core_4th_gen_avx`.
`pentium`	Intel® Pentium® processor
`pentium_4`	Intel® Pentium® 4 processor
`pentium_4_sse3`	Intel® Pentium® 4 processor with Intel® Streaming SIMD Extensions 3 (Intel® SSE3) instructions, Intel® Core™ Duo processors, Intel® Core™ Solo processors
`pentium_ii`	Intel® Pentium® II processors
`pentium_iii`	Intel® Pentium® III processors
`pentium_iii_no_xmm_regs`	Intel® Pentium® III processors with no XMM registers
`pentium_m`	Intel® Pentium® M processors
`pentium_mmx`	Intel® Pentium® processors with MMX™ technology
`pentium_pro`	Intel® Pentium® Pro processors
`skylake`	Intel® microarchitecture code name Skylake. This keyword targets the Client CPU *without* support for Intel® AVX-512 instructions.

`skylake_avx512`	Intel® microarchitecture code name Skylake. This keyword targets the Server CPU *with* support for Intel® AVX-512 instructions.

The vector version of the routine that is created by the compiler is not affected by processor options specified on the command line.

Multiple PROCESSOR clauses cause a syntax error.

NOTE
ifx does not support compilation for 32-bit architectures; only *cpuid* values for 64-bit instruction sets may be specified for ifx.

DECLARE SIMD
ATTRIBUTES VECTOR

PRODUCT
Transformational Intrinsic Function (Generic):
Returns the product of all the elements in an entire array or in a specified dimension of an array.

Syntax
`result = PRODUCT (array [, mask])`

`result = PRODUCT (array, dim [, mask])`

array	(Input) Must be an array of type integer, real, or complex.
dim	(Input) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.

Results
The result is an array or a scalar of the same data type as *array*.

The result is a scalar if *dim* is not specified or *array* has rank one.

The following rules apply if *dim* is not specified:

- If PRODUCT(*array*) is specified, the result is the product of all elements of *array*. If *array* has size zero, the result is 1.
- If PRODUCT(*array*, MASK= *mask*) is specified, the result is the product of all elements of *array* corresponding to true elements of *mask*. If *array* has size zero, or every element of *mask* has the value .FALSE., the result is 1.

The following rules apply if *dim* is specified:

- If *array* has rank one, the value is the same as PRODUCT(*array*[,MASK= *mask*]).
- An array result has a rank that is one less than *array*, and shape $(d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)$, where $(d_1, d_2, ..., d_n)$ is the shape of *array*.
- The value of element $(s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)$ of PRODUCT(*array*, *dim*[, *mask*]) is equal to PRODUCT(*array*$(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)$ [,MASK= *mask*$(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)$]).

Example

PRODUCT ((/2, 3, 4/)) returns the value 24 (the product of 2 * 3 * 4). PRODUCT ((/2, 3, 4/), DIM=1) returns the same result.

PRODUCT (C, MASK=C .LT. 0.0) returns the product of the negative elements of C.

A is the array

```
  [ 1  4  7 ]
  [ 2  3  5 ].
```

PRODUCT (A, DIM=1) returns the value (2, 12, 35), which is the product of all elements in each column. 2 is the product of 1 * 2 in column 1. 12 is the product of 4 * 3 in column 2, and so forth.

PRODUCT (A, DIM=2) returns the value (28, 30), which is the product of all elements in each row. 28 is the product of 1 * 4 * 7 in row 1. 30 is the product of 2 * 3 * 5 in row 2.

If *array* has shape (2, 2, 2), *mask* is omitted, and *dim* is 1, the result is an array result with shape (2, 2) whose elements have the following values.

Resultant array element	Value
result(1, 1)	*array*(1, 1, 1) * *array*(2, 1, 1)
result(2, 1)	*array*(1, 2, 1) * *array*(2, 2, 1)
result(1, 2)	*array*(1, 1, 2) * *array*(2, 1, 2)
result(2, 2)	*array*(1, 2, 2) * *array*(2, 2, 2)

The following shows another example:

```
INTEGER array (2, 3)
INTEGER AR1(3), AR2(2)
array = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2,3/))
! array is  1 2 3
!           4 5 6
AR1 = PRODUCT(array, DIM = 1) ! returns [ 4 10 18 ]
AR2 = PRODUCT(array, MASK = array .LT. 6, DIM = 2)
                                  ! returns [ 6 20 ]
END
```

SUM

PROGRAM

Statement: *Identifies the program unit as a main program and gives it a name.*

Syntax

```
[PROGRAM name]
   [specification-part]
   [execution-part]
[CONTAINS
   internal-subprogram-part]
END[PROGRAM [name]]
```

name	Is the name of the program.
specification-part	Is one or more specification statements, except for the following: • INTENT (or its equivalent attribute) • OPTIONAL (or its equivalent attribute) • PUBLIC and PRIVATE (or their equivalent attributes) An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.
execution-part	Is one or more executable constructs or statements, except for ENTRY or RETURN statements.
internal-subprogram-part	Is one or more internal subprograms (defining internal procedures). The *internal-subprogram-part* is preceded by a CONTAINS statement.

Description

The PROGRAM statement is optional. Within a program unit, a PROGRAM statement can be preceded only by comment lines or an OPTIONS statement.

The END statement is the only required part of a program. If a name follows the END statement, it must be the same as the name specified in the PROGRAM statement.

The program name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A main program must not reference itself (either directly or indirectly).

Example

The following is an example of a main program:

```
PROGRAM TEST
  INTEGER C, D, E(20,20)     ! Specification part
  CALL SUB_1                 ! Executable part
...
CONTAINS
  SUBROUTINE SUB_1           ! Internal subprogram
  ...
  END SUBROUTINE SUB_1
END PROGRAM TEST
```

The following shows another example:

```
PROGRAM MyProg
PRINT *, 'hello world'
END
```

PROTECTED

Statement and Attribute: *Specifies limitations on the use of module entities.*

Syntax

The PROTECTED attribute can be specified in a type declaration statement or a PROTECTED statement, and takes one of the following forms:

Type Declaration Statement:

`type, [att-ls, ] PROTECTED [, att-ls] :: entity[, entity] ...`

Statement:

`PROTECTED [::]entity[, entity] ...`

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
entity	Is the name of an entity in a module.

The PROTECTED attribute can only appear in the specification part of a module.

The PROTECTED attribute can only be specified for a procedure pointer or named variable that is not in a common block.

A non-pointer object that has the PROTECTED attribute and is accessed by use association can not appear in a variable definition or as the target in a pointer assignment statement.

A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as any of the following:

- A *pointer-object* in a NULLIFY statement
- A *pointer-object* in a pointer assignment statement
- An *object* in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following restrictions apply outside of the module in which the entity has been given the PROTECTED attribute:

- A non-pointer entity may not be defined or redefined.
- A pointer entity may not have its association status changed through the pointer.
- A data entity with the TARGET and the PROTECTED attribute that is USE associated may not appear in a pointer initialization expression or a constructor if it corresponds to a pointer component.

Example

The following example shows a type declaration statement specifying the PROTECTED attribute:

```
INTEGER, PROTECTED :: D, E
```

Consider the following example:

```
MODULE counter_mod
  INTEGER, PROTECTED :: current = 0
  CONTAINS

  INTEGER FUNCTION next()
  current = current + 1    ! current can be modified here
  next = current
  RETURN
  END FUNCTION next
END MODULE counter_mod

PROGRAM test_counter
USE counter_mod
PRINT *, next( )             ! Prints 1
current = 42                 ! Error: variable is protected
END PROGRAM test_counter
```

PSECT

General Compiler Directive: *Modifies characteristics of a common block.*

Syntax

```
!DIR$ PSECT /common-name/ a[,a] ...
```

common-name

Is the name of the common block. The slashes (/) are required.

a

Is one of the following:

- ALIGN= *val* or ALIGN= *keyword*

  Specifies minimum alignment for the common block. ALIGN only has an effect when specified on Windows* and Linux* systems.

  The *val* is a constant ranging from 0 through 6 on Windows* systems and 0 through 4 on Linux* systems. The specified number is interpreted as a power of 2. The value of the expression is the alignment in bytes.

  The *keyword* is one of the following:

Keyword	Equivalent to *val*
BYTE	0
WORD	1
LONG	2
QUAD	3
OCTA	4
PAGE	On IA-32 architecture: range is 0 through 13 for Windows*; 0 through 12 for Linux*

- [NO]WRT

  Determines whether the contents of a common block can be modified during program execution.

If one program unit changes one or more characteristics of a common block, all other units that reference that common block must also change those characteristics in the same way.

The defaults are ALIGN=OCTA and WRT.

Syntax Rules for Compiler Directives

PUBLIC

Statement and Attribute: *Specifies that entities in a module can be accessed from outside the module by specifying a USE statement.*

Syntax

The PUBLIC attribute can be specified in a type declaration statement or a PUBLIC statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] PUBLIC [, *att-ls*] :: *entity* [, *entity*]...

Statement:

PUBLIC [[::] *entity* [, *entity*] ...]

type — Is a data type specifier.

att-ls — Is an optional list of attribute specifiers.

entity — Is one of the following:

- A variable name
- A procedure name
- A derived type name
- A named constant
- A namelist group name
- An OpenMP* reduction-identifier

In statement form, an entity can also be one of the following:

- A module name
- A generic name
- A defined operator
- A defined assignment
- A defined I/O generic specification

Description

The PUBLIC attribute can only appear in the scoping unit of a module.

Only one PUBLIC statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by use association.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility for all entities in the module and entities accessible from other modules by use association.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PUBLIC statement, the module name must have appeared in a USE statement within the same scoping unit.

A PUBLIC attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies that the derived-type definition is accessible by USE association where the module is used.

A PUBLIC attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is accessible by USE association where the module is used, even if the default accessibility of the components and type-bound procedures of the derived type has been set to PRIVATE in the definition of the derived type.

If a derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module procedure has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the derived-type definition or in the module's descendants.

Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```
REAL,  PRIVATE  :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
  PRIVATE RESTRICTED_DATA
END MODULE
```

The following example shows a PUBLIC type with PRIVATE components:

```
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```
 ! LENGTH in module VECTRLEN calculates the length of a 2-D vector.
 ! The module contains both private and public procedures
    MODULE VECTRLEN
      PRIVATE SQUARE
      PUBLIC LENGTH
     CONTAINS
     SUBROUTINE LENGTH(x,y,z)
        REAL,INTENT(IN) x,y
        REAL,INTENT(OUT) z
```

```
      CALL SQUARE(x,y)
      z = SQRT(x + y)
      RETURN
   END SUBROUTINE
   SUBROUTINE SQUARE(x1,y1)
      REAL x1,y1
      x1 = x1**2
      y1 = y1**2
      RETURN
   END SUBROUTINE
  END MODULE
```

PURE

Keyword: *Asserts that a user-defined procedure has no side effects.*

Description

This kind of procedure is specified by using the prefix PURE or the prefix ELEMENTAL without the prefix IMPURE in a FUNCTION or SUBROUTINE statement.

A pure procedure has no side effects. It has no effect on the state of the program, except for the following:

- For functions: It returns a value.
- For subroutines: It modifies INTENT(OUT) and INTENT(INOUT) parameters.

The following intrinsic and library procedures are implicitly pure:

- All intrinsic functions
- The elemental intrinsic subroutine MVBITS
- The intrinsic subroutine MOVE_ALLOC
- Intrinsic module procedures that are specified to be pure

A dummy procedure or a procedure pointer can be specified to be pure. A type-bound procedure that is bound to a pure procedure is also pure.

A statement function is pure only if all functions that it references are pure and its definition does not reference any data object with the VOLATILE attribute.

Except for procedure arguments and pointer arguments, the following intent must be specified in the specification part of the procedure for all dummy arguments:

- For functions: INTENT(IN) or the VALUE attribute
- For subroutines: any INTENT (IN, OUT, or INOUT) or the VALUE attribute

A local variable declared in a pure procedure (including variables declared in any internal procedure) must not:

- Specify the SAVE attribute
- Specify the VOLATILE attribute

- Be initialized in a type declaration statement or a DATA statement

The following variables have restricted use in pure procedures (and any internal procedures):

- Global variables
- Dummy arguments with INTENT(IN)
- Dummy arguments with no declared intent that do not have the VALUE attribute
- Objects that are storage associated with any part of a global variable

They must not be used in any context that does either of the following:

- Causes their value to change. For example, they must not be used as any of the following:
  - The left side of an assignment statement or pointer assignment statement
  - An actual argument associated with a dummy argument with INTENT(OUT), INTENT(INOUT), or the POINTER attribute
  - An index variable in a DO or FORALL statement, or an implied-DO clause
  - The variable in an ASSIGN statement
  - An input item in a READ statement
  - An internal file unit in a WRITE statement
  - An object in an ALLOCATE, DEALLOCATE, or NULLIFY statement
  - An IOSTAT or SIZE specifier in an I/O statement, the STAT or ERRMSG specifier in a ALLOCATE, DEALLOCATE, or image control statement, or as the STAT or ERRMSG argument to the intrinsic MOVE_ALLOC, or a collective or atomic intrinsic subroutine.
  - The CMDSTAT or CMDMSG argument to the EXECUTE_COMMAND_LINE intrinsic subroutine
  - The STATUS or ERRMSG argument to the GET_COMMAND or GET_COMMAND_ARGUMENT intrinsic subroutine
- Creates a pointer to that variable. For example, they must not be used as:
  - The target in a pointer assignment statement
  - The right side of an assignment to a derived-type variable (including a pointer to a derived type) if the derived type has a pointer component at any level
  - The actual argument to the C_LOC function defined in the intrinsic module ISO_C_BINDING

A pure procedure must not contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement; ERROR STOP is permitted
- An image control statement
- An OpenMP* directive that is *not* a PURE directive

A pure procedure can be used in contexts where other procedures are restricted; for example:

- It can be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It can be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, defined input/output, or finalization.
- It can be passed as an actual argument to a pure procedure.

If a procedure is used in any of these contexts, its interface must be explicit and it must be declared pure in that interface.

Example

Consider the following:

```
PURE FUNCTION DOUBLE(X)
  REAL, INTENT(IN) :: X
  DOUBLE = 2 * X
END FUNCTION DOUBLE
```

The following shows another example:

```
PURE INTEGER FUNCTION MANDELBROT(X)
  COMPLEX, INTENT(IN) :: X
  COMPLEX :: XTMP
  INTEGER :: K
  ! Assume SHARED_DEFS includes the declaration
  ! INTEGER ITOL
  USE SHARED_DEFS

  K = 0
  XTMP = -X
  DO WHILE (ABS(XTMP) < 2.0 .AND. K < ITOL)
    XTMP = XTMP**2 - X
    K = K + 1
  END DO
  MANDELBROT = K
END FUNCTION
```

The following shows the preceding function used in an interface block:

```
INTERFACE
  PURE INTEGER FUNCTION MANDELBROT(X)
    COMPLEX, INTENT(IN) :: X
  END FUNCTION MANDELBROT
END INTERFACE
```

The following shows a FORALL construct calling the MANDELBROT function to update all the elements of an array:

```
FORALL (I = 1:N, J = 1:M)
  A(I,J) = MANDELBROT(COMPLX((I-1)*1.0/(N-1), (J-1)*1.0/(M-1))
END FORALL
```

SUBROUTINE
FORALL
ELEMENTAL prefix

PUTC

Portability Function: *Writes a character to Fortran external unit number 6.*

Module

USE IFPORT

Syntax

`result = PUTC (char)`

char	(Input) Character. Character to be written to external unit 6.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Example

```
use IFPORT
integer(4) i4
character*1 char1
do i = 1,26
  char1 = char(123-i)
  i4 = putc(char1)
  if (i4.ne.0) iflag = 1
enddo
```

Q to R

This section describes language features that start with Q or R.

Q to R

QCMPLX

Elemental Intrinsic Function (Specific): *Converts an argument to COMPLEX(16) type. This function cannot be passed as an actual argument.*

Syntax

`result = QCMPLX (x[,y])`

x	(Input) Must be of type integer, real, or complex.
y	(Input; optional) Must be of type integer or real. It must not be present if *x* is of type complex.

Results

The result type is COMPLEX(16) (or COMPLEX*32).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If *y* is not specified and *x* is complex, the result value is CMPLX(REAL(*x*), AIMAG(*x*)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

QCMPLX(*x*, *y*) has the complex value whose real part is REAL(*x*, *kind*=16) and whose imaginary part is REAL(*y*, *kind*=16).

Example

QCMPLX (-3) has the value (-3.0Q0, 0.0Q0).

QCMPLX (4.1, 2.3) has the value (4.1Q0, 2.3Q0).

See Also

CMPLX
DCMPLX
FLOAT

INT
IFIX
REAL
SNGL

QEXT

Elemental Intrinsic Function (Generic): *Converts a number to quad precision (REAL(16)) type.*

Syntax

```
result = QEXT (a)
```

a (Input) Must be of type integer, real, or complex.

Results

The result type is REAL(16) (REAL*16). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If *a* is of type REAL(16), the result is the value of the *a* with no conversion (QEXT(a) = a).

If *a* is of type integer or real, the result has as much precision of the significant part of *a* as a REAL(16) value can contain.

If *a* is of type complex, the result has as much precision of the significant part of the real part of *a* as a REAL(16) value can contain.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1)	REAL(16)
	INTEGER(2)	REAL(16)
	INTEGER(4)	REAL(16)
	INTEGER(8)	REAL(16)
QEXT	REAL(4)	REAL(16)
QEXTD	REAL(8)	REAL(16)
	REAL(16)	REAL(16)
	COMPLEX(4)	REAL(16)
	COMPLEX(8)	REAL(16)
	COMPLEX(16)	REAL(16)

[1]These specific functions cannot be passed as actual arguments.

Example

QEXT (4) has the value 4.0 (rounded; there are 32 places to the right of the decimal point).

QEXT ((3.4, 2.0)) has the value 3.4 (rounded; there are 32 places to the right of the decimal point).

QFLOAT

Elemental Intrinsic Function (Generic): *Converts an integer to quad precision (REAL(16)) type.*

Syntax

```
result = QFLOAT (a)
```

a (Input) Must be of type integer.

Results

The result type is REAL(16) (REAL*16).

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

Example

QFLOAT (-4) has the value -4.0 (rounded; there are 32 places to the right of the decimal point).

QNUM

Elemental Intrinsic Function (Specific): *Converts a character string to a REAL(16) value. This function cannot be passed as an actual argument.*

Syntax

```
result = QNUM (i)
```

i (Input) Must be of type character.

Results

The result type is REAL(16). The result value is the real value represented by the character string *i*.

Example

QNUM ("-174.23") has the value -174.23 of type REAL(16).

QRANSET

Portability Subroutine: *Sets the seed for a sequence of pseudo-random numbers.*

Module

USE IFPORT

Syntax

```
CALL QRANSET (rseed)
```

rseed (Input) INTEGER(4). The reset value for the seed.

QREAL

Elemental Intrinsic Function (Specific): *Converts the real part of a COMPLEX(16) argument to REAL(16) type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.*

Syntax

```
result = QREAL (a)
```

a (Input) Must be of type COMPLEX(16) (or COMPLEX*32).

Results

The result type is quad-precision real (REAL(16) or REAL*16).

Example

QREAL ((2.0q0, 3.0q0)) has the value 2.0q0.

REAL
DREAL

QSORT

Portability Subroutine: *Performs a quick sort on an array of rank one.*

Module

USE IFPORT

Syntax

CALL QSORT (*array*,*len*,*isize*,*compar*)

array (Input) Any type except assumed-length character. A one-dimensional array to be sorted.

If the data type does not conform to one of the predefined interfaces for QSORT, you may have to create a new interface (see Note and Example below).

len (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in *array*.

isize (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Size, in bytes, of a single element of *array*:

- 4 if array is of type REAL(4)
- 8 if array is of type REAL(8) or complex
- 16 if array is of type COMPLEX(8)

compar (Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of *compar* takes the form:

INTEGER(2) FUNCTION *compar*(*arg1*, *arg2*)

where *arg1* and *arg2* have the same type as *array* (above) and are not assumed-length character. Assume-length characters should be wrapped in a derived type. After you have created an ordering scheme, implement your sorting function so that it returns the following:

- Negative if arg1 should precede arg2
- Zero if arg1 is equivalent to arg2
- Positive if arg1 should follow arg2

Dummy argument *compar* must be declared as external.

In place of an INTEGER kind, you can specify the constant SIZEOF_SIZE_T, defined in `IFPORT.F90`, for argument *len* or *isize*. Use of this constant ensures correct compilation.

NOTE
If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module's source file, `IFPORT.F90`.

Example

```
! program showing how to call 'QSORT' on
! a user-defined type.
!
! Define the type to be shared.
!
module share_type
    type element_type
        integer       :: data
        character(10) :: key
    end type
end module

! Main program calls QSORT.
!
program main

    use, intrinsic :: iso_c_binding, only: c_size_t
    use IFPORT       ! To get QSORT
    use share_type   ! To get shared type

    ! Define an overload of the default QSORT signature
    ! with a signature using the shared type.
    !
    interface
        subroutine QSORT_element_types(array, len, isize, comp)
           use, intrinsic :: iso_c_binding, only:c_size_t
           use share_type
           type(element_type) array(len)
           integer(C_SIZE_T) len, isize
           integer(2), external :: comp
           !
           ! Hook the overload to the real thing but be careful
           ! to connect to the correct qsort: the Fortran one, not
           ! the C one!
           !
           ! We need to call the _Fortran_ qsort, not the _C_ one, or
           ! there will be errors from the 1-origin vs. 0-origin indexing
           ! and the row-major vs. column-major ordering.
           !
           ! The symptom is that "OrderCharCI" is called with pointer values
           ! which are outside the bounds of the array to be sorted.
           !
           !DIR$ IF DEFINED(_WIN64)
```

```
          !DIR$ ATTRIBUTES ALIAS:'QSORT' :: QSORT_element_types
          !DIR$ ELSE
          !DIR$ ATTRIBUTES ALIAS: '_QSORT' :: QSORT_element_types
          !DIR$ ENDIF
        end subroutine QSORT_element_types
    end interface

    type(element_type) :: c(7)

    integer(2), external :: OrderCharCI

    integer (C_SIZE_T) :: size_of_element, size_of_array
    ! Fill in the array to be sorted.  The data value is chosen so
    ! that the sorted array will have the values in numeric order.
    ! Thus we can check the result of the sort.
    !
    c(1)%key  = 'aisjdop'
    c(1)%data = 3
    c(2)%key  = '35djf2'
    c(2)%data = 1
    c(3)%key  = 'ss:ss'
    c(3)%data = 6
    c(4)%key  = 'MMhQQ'
    c(4)%data = 4
    c(5)%key  = 'mmHqq'
    c(5)%data = 5
    c(6)%key  = 'aaaa'
    c(6)%data = 2
    c(7)%key  = '["\/'
    c(7)%data = 7

    size_of_array   = size(c)         !  7
    size_of_element = sizeof(c(1))    ! 16

    write(*,*) '"C" is:'
    do i = 1, 7
        write(*,*) ' "', c(i)%key, '" value ', c(i)%data
    end do

    write(*,*) ' '
    write(*,*) 'size of C is            ', size_of_array, ' elements'
    write(*,*) 'size of element C(1) is ', size_of_element, ' bytes'
    write(*,*) 'len of key in C(1) is   ',   len(c(1)%key)
    write(*,*) ' '

    ! Call the overloaded QSORT routine.
    !
    Call QSort_element_types(C, size_of_array, size_of_element, OrderCharCI)

    write(*,*) 'Sorted "C" is '
    do i = 1, 7
         write(*,*) ' "', c(i)%key, '" value ', c(i)%data
    end do

end program main

! Computes order of character strings using a case insensitive ordering.
!
```

```
! Return -1 if C1 before C2, 0 if C1 = C2, and 1 if C1 after C2.
!
! Called first with the pair (2,3), then (1,2), then (1,3)...when passing
! character strings of length 10.
!
! Passing "element_type" objects, it's called first with the pair (1, <invalid>),
! and the second item has a address well before the beginning of "C".
!

function OrderCharCI(c1, c2)
    use share_type

    implicit none

    type(element_type), intent(in) :: c1 ! Character strings to be ordered.
    type(element_type), intent(in) :: c2 !

    ! Function result:
    !
    integer(2) :: OrderCharCI

    ! Locals:
    !
    character(10) :: c1L !} Local copies of c1 and c2.
    character(10) :: c2L !}

    integer :: i ! Loop index.

    write(*,*)'OrderCharCI, parameter C1 is "', c1%key, '" ', c1%data, ', len is ', len(c1%key)
    write(*,*)' len_trim is ', len_trim(c1%key)
    write(*,*) ' '

    ! SEGV on access to C2
    !
    write(*,*)'OrderCharCI, parameter C2 is "', c2%key, '" ', c2%data, ', len is ', len(c2%key)
    write(*,*)' len_trim is ', len_trim(c2%key)
    write(*,*) ' '
    c1L = c1%key
    c2L = c2%key

    write(*,*) 'about to start do loop'

    do i = 1, len_trim(C1L)
        if ('a' <= C1L(i:i) .and. c1L(i:i) <= 'z') c1L(i:i) = char(ichar(c1L(i:i)) - ichar('a')
+ ichar('A'))
    end do
    do i = 1, len_trim(C2L)
        if ('a' <= c2L(i:i) .and. c2L(i:i) <= 'z') c2L(i:i) = char(ichar(c2L(i:i)) - ichar('a')
+ ichar('A'))
    end do
    if (c1L == c2L) Then
        OrderCharCI = 0
        write(*,*) ' - equal'
    else if (c1L < c2L) Then
        OrderCharCI = -1
        write(*,*) ' - c1 is less'
    else
        OrderCharCI = 1
```

```
        write(*,*) ' - c1 is more'
    end if
end function OrderCharCI
```

The following shows another example:

```
PROGRAM SORTQ
   use, intrinsic :: iso_c_binding, only: c_size_t
   use IFPORT
   integer(2), external :: cmp_function
   integer(2) insort(26), i
   integer (C_SIZE_T) array_len, array_size
   array_len = 26
   array_size = 2
   do i=90,65,-1
     insort(i-64)=91 - i
   end do
   print *, "Before: "
   print *,insort
   CALL qsort(insort,array_len,array_size,cmp_function)
   print *, 'After: '
   print *, insort
END
!
   integer(2) function cmp_function(a1, a2)
   integer(2) a1, a2
   cmp_function=a1-a2
   end function
```

RADIX

Inquiry Intrinsic Function (Generic): *Returns the base of the model representing numbers of the same type and kind as the argument.*

Syntax

`result = RADIX (x)`

x	(Input) Must be of type integer or real; it can be scalar or array valued.

Results

The result is a scalar of type default integer. For an integer argument, the result has the value r (as defined in Model for Integer Data). For a real argument, the result has the value b (as defined in Model for Real Data).

Example

If X is a REAL(4) value, RADIX (X) has the value 2.

RAISEQQ

Portability Function: *Sends a signal to the executing program.*

Module

USE IFPORT

Syntax

`result = RAISEQQ (sig)`

sig (Input) INTEGER(4). Signal to raise. One of the following constants (defined in `IFPORT.F90`):

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+Csignal
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

If a signal-handling routine for *sig* has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).

SIGNAL
KILL

RAN

Nonelemental Intrinsic Function (Specific): *Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.*

Syntax

`result = RAN (i)`

i (Input; output) Must be an INTEGER(4) variable or array element.

It should initially be set to a large, odd integer value. The RAN function stores a value in the argument that is later used to calculate the next random number.

There are no restrictions on the seed, although it should be initialized with different values on separate runs to obtain different random numbers.

Results

The result type is REAL(4). The result is a floating-point number that is uniformly distributed in the range between 0.0 inclusive and 1.0 exclusive. The result is set equal to the value associated with the argument *i*.

RAN is not a pure function.

Example

In RAN (*I*), if variable *I* has the value 3, RAN has the value 4.8220158E-05.

See Also

RANDOM
RANDOM_NUMBER

RAND, RANDOM

Portability Functions: *Return real random numbers in the range 0.0 to 1.0, not including the end points.*

Module

USE IFPORT

Syntax

```
result = RAND ([ iflag ])
result = RANDOM (iflag)
```

iflag (Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

Results

The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 to 1.0, not including the end points.

Value of *iflag*	Selection process
1	The generator is restarted and the first random value is selected.
0	The next random number in the sequence is selected.
Otherwise	The generator is reseeded using *iflag*, restarted, and the first random value is selected.

When RAND is called without an argument, the following applies:

- The value of *iflag* is assumed to be 0.
- You must specify USE IFPORT.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them.

The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

You can use SRAND to restart the pseudorandom number generator used by RAND.

NOTE
RANDOM is available as a function or subroutine.

Example

The following example shows how to use both the RANDOM function and the RANDOM subroutine:

```
use ifport
real(4) ranval
call seed(1995) ! initialize
call random(ranval) ! get next random number
print *,ranval

ranval = random(1) ! initialize
ranval = random(0) ! get next random number

print *,ranval
end
```

See Also

RANDOM_INIT

RANDOM_NUMBER
RANDOM_SEED
SRAND

RANDOM Subroutine

Portability Subroutine: *Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.*

Module

USE IFPORT

Syntax

`CALL RANDOM (ranval)`

ranval	(Output) REAL(4). Pseudorandom number, 0 *ranval*< 1, from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in `IFCORE.F90`) to SEED before the first call to RANDOM.

The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.

Example

```
USE IFPORT
REAL(4) ran

CALL SEED(1995)
CALL RANDOM(ran)
```

The following example shows how to use both the RANDOM subroutine and the RANDOM function:

```
use ifport
real(4) ranval
! from libifcore.lib
call seed(1995)     ! initialize
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number

print *,ranval
! from libifport.lib
ranval = random(1)  ! initialize
! same
ranval = random(0)  ! get next random number

print *,ranval
end
```

RANDOM_INIT

Intrinsic Subroutine: *Initializes the pseudorandom number generator used by RANDOM_NUMBER.*

Syntax

CALL RANDOM_INIT (*repeatable*, *image_distinct*)

repeatable	(Input) Must be scalar of type logical.
image_distinct	(Input) Must be scalar of type logical.

If *repeatable* has the value .true. and *image_distinct* has the value .true., the effect of a call to RANDOM_INIT is equivalent to calling RANDOM_SEED with a different processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is the same each time the program is executed.

If *repeatable* has the value .true. and *image_distinct* has the value .false., the effect of a call to RANDOM_INIT is equivalent to calling RANDOM_SEED with the same processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is the same each time the program is executed.

If *repeatable* has the value .false. and *image_distinct* has the value .true., the effect of a call to RANDOM_INIT is equivalent to calling RANDOM_SEED with a different processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is different each time the program is executed.

If *repeatable* has the value .false. and *image_distinct* has the value .false., the effect of a call to RANDOM_INIT is equivalent to calling RANDOM_SEED with the same processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is the different each time the program is executed.

NOTE
This routine is thread safe.

Example

Consider the following:

```
PROGRAM main
REAL,DIMENSION(1000) :: y
CALL RANDOM_INIT (REPEATABLE=.TRUE., IMAGE_DISTINCT=.TRUE.)
CALL RANDOM_NUMBER (y)
. . .
END
```

After executing the above code, the array y contains a different sequence of pseudorandom numbers on each image that executes the code. If the program is executed multiple times, for an image that has the same image index in the initial team, the value of y is the same each time the program is run.

Consider another example:

```
PROGRAM main
REAL,DIMENSION(1000) :: y
CALL RANDOM_INIT (REPEATABLE=.FALSE., IMAGE_DISTINCT=.FALSE.)
CALL RANDOM_NUMBER (y)
. . .
END
```

After executing the above code, the array y contains the same sequence of pseudorandom numbers on each image that executes the code. If the program is executed multiple times, the value of y is different each time the program is run.

RAN
RAND and RANDOM

RANDOM_NUMBER

Intrinsic Subroutine: *Returns one pseudorandom number or an array of such numbers.*

Syntax

```
CALL RANDOM_NUMBER (harvest)
```

harvest	(Output) Must be of type real. It can be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution within the range 0 <= *x* < 1.

The seed for the pseudorandom number generator used by RANDOM_NUMBER can be set or queried with RANDOM_SEED. If RANDOM_SEED is not used, the processor sets the seed for RANDOM_NUMBER to a processor-dependent value.

The RANDOM_NUMBER generator uses two separate congruential generators together to produce a period of approximately 10**18, and produces real pseudorandom results with a uniform distribution in [0, 1). It accepts two integer seeds, the first of which is reduced to the range [1, 2147483562]. The second seed is reduced to the range [1, 2147483398]. This means that the generator effectively uses two 31-bit seeds.

The RANDOM_NUMBER generator does not produce subnormal numbers.

For more information on the algorithm, see the following:

- Communications of the ACM vol 31 num 6 June 1988, titled: Efficient and Portable Combined Random Number Generators by Pierre L'ecuyer.
- Springer-Verlag New York, N. Y. 2nd ed. 1987, titled: A Guide to Simulation by Bratley, P., Fox, B. L., and Schrage, L. E.

NOTE
This routine is thread safe.

Example

Consider the following:

```
REAL Y, Z (5, 5)
! Initialize Y with a pseudorandom number
CALL RANDOM_NUMBER (HARVEST = Y)
CALL RANDOM_NUMBER (Z)
```

Y and Z contain uniformly distributed random numbers.

The following shows another example:

```
REAL x, array1 (5, 5)
CALL RANDOM_SEED()
CALL RANDOM_NUMBER(x)
CALL RANDOM_NUMBER(array1)
```

The following shows another example:

```
 program testrand
   intrinsic random_seed, random_number
   integer size
   integer, allocatable :: seed(:), gseed(:), hiseed(:), zseed(:)
   real harvest(10)
   call random_seed(SIZE=size)
   print *,"size ",size
   allocate(seed(size),gseed(size),hiseed(size),zseed(size))
   hiseed = -1
   zseed = 0
   seed = 123456789
   seed(size) = 987654321
```

```
   call random_seed(PUT=hiseed(1:size))
   call random_seed(GET=gseed(1:size))
   print *,"hiseed gseed", hiseed, gseed
   call random_seed(PUT=zseed(1:size))
   call random_seed(GET=gseed(1:size))
   print *,"zseed gseed ", zseed, gseed
   call random_seed(PUT=seed(1:size))
   call random_seed(GET=gseed(1:size))
   call random_number(HARVEST=harvest)
   print *, "seed gseed ", seed, gseed
   print *, "harvest"
   print *, harvest
   call random_seed(GET=gseed(1:size))
   print *,"gseed after harvest ", gseed
end program testrand
```

SEED
DRAND and DRANDM
IRAND and IRANDM
RAN
RAND and RANDOM

RANDOM_SEED

Intrinsic Subroutine (Generic): *Changes or queries the seed (starting point) for the pseudorandom number generator used by intrinsic subroutine RANDOM_NUMBER. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

`CALL RANDOM_SEED ([size] [,put] [,get])`

size	(Output; optional) Must be scalar and of type integer. Set to the number of integers (N) that the processor uses to hold the value of the seed.
put	(Input; optional) Must be an integer array of rank one and size greater than or equal to N. It is used to reset the value of the seed.
get	(Output; optional) Must be an integer array of rank one and size greater than or equal to N. It is set to the current value of the seed.

No more than one argument can be specified. If no argument is specified, a random number based on the date and time is assigned to the seed.

You can determine the size of the array the processor uses to store the seed by calling RANDOM_SEED with the *size* argument (see the second example below).

If RANDOM_SEED is called with no arguments, the seed is set to a different, unpredictable value on each call.

NOTE
This routine is thread safe.

Example

Consider the following:

```
CALL RANDOM_SEED                        ! Processor initializes the
                                        !   seed randomly from the date
                                        !   and time
CALL RANDOM_SEED (SIZE = M)             ! Sets M to N
CALL RANDOM_SEED (PUT = SEED (1 : M))   ! Sets user seed
CALL RANDOM_SEED (GET = OLD  (1 : M))   ! Reads the current seed
```

The following shows another example:

```
INTEGER I
INTEGER, ALLOCATABLE :: new (:), old(:)
CALL RANDOM_SEED ( )  ! Processor reinitializes the seed
                      ! randomly from the date and time
CALL RANDOM_SEED (SIZE = I)  ! I is set to the size of
                             ! the seed array
ALLOCATE (new(I))
ALLOCATE (old(I))
CALL RANDOM_SEED (GET=old(1:I)) ! Gets the current seed
WRITE(*,*) old
new = 5
CALL RANDOM_SEED (PUT=new(1:I)) ! Sets seed from array
                                ! new
END
```

RANDOM_INIT

RANDOM_NUMBER
SEED
SRAND

RANDU

Intrinsic Subroutine (Generic): *Computes a pseudorandom number as a single-precision value. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

`CALL RANDU (i1,i2,x)`

i1, i2	(Input; output) Must be scalars of type INTEGER(2) or INTEGER(4). They contain the *seed* for computing the random number. These values are updated during the computation so that they contain the updated seed.
x	(Output) Must be a scalar of type REAL(4). This is where the computed random number is returned.

The result is returned in *x*, which must be of type REAL(4). The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for *i1* and *i2*.

The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for *i1* and *i2*.

If *i1* = 0 and *i2* = 0, the generator base is set as follows:

```
    x(n + 1) = 2**16 + 3
```

Otherwise, it is set as follows:

```
    x(n + 1) = (2**16 + 3) * x(n) mod 2**32
```

The generator base x(n + 1) is stored in *i1*, *i2*. The result is x(n + 1) scaled to a real value y(n + 1), for 0.0 <= y(n + 1) < 1.

Example

Consider the following:

```
REAL X
INTEGER(2) I, J
...
CALL RANDU (I, J, X)
```

If I and J are values 4 and 6, X has the value 5.4932479E-04.

RANF Intrinsic Procedure

Elemental Intrinsic Function (Generic): *Generates a random number between 0.0 and RAND_MAX. This function must not be passed as an actual argument. RANF can be used as an intrinsic procedure or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.*

Syntax

```
result = RANF ()
```

Results

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and (2**31) - 1.

The initial seed is set by the following:

```
  CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

The intrinsic function RANF generates a different sequence of random numbers than the RANF portability function generates for the same seed. The intrinsic function RANF used inside a loop can be vectorized into one call that returns four results, but the portability function RANF cannot be so optimized.

SRAND

RANF Portability Routine

Portability Function: *Generates a random number between 0.0 and RAND_MAX. RANF can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.*

Module

USE IFPORT

Syntax

```
result = RANF ( )
```

Results

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and (2**31) - 1.

The initial seed is set by the following:

```
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

RANDOM_NUMBER

RANF intrinsic procedure

SRAND

RANGE

Inquiry Intrinsic Function (Generic): *Returns the decimal exponent range in the model representing numbers with the same kind parameter as the argument.*

Syntax

```
result = RANGE (x)
```

x	(Input) Must be of type integer, real, or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

For an integer argument, the result has the value INT(LOG10(HUGE(*x*))). For information on the integer model, see Model for Integer Data.

For a real or complex argument, the result has the value INT(MIN (LOG10(HUGE(*x*)), -LOG10(TINY(*x*)))). For information on the real model, see Model for Real Data.

Example

If X is a REAL(4) value, RANGE (X) has the value 37. (HUGE(X) = $(1 - 2^{-24}) \times 2^{128}$ and TINY(X) = 2^{-126})

HUGE

TINY

RANGET

Portability Subroutine: *Returns the current seed.*

Module

USE IFPORT

Syntax

```
CALL RANGET (seed)
```

seed	(Output) INTEGER(4). The current seed value.

RANK

Inquiry Intrinsic Function (Generic): *Returns the rank of a data object.*

Syntax

```
result = RANK (a)
```

a	(Input) Is a data object. It can be of any type.

Results

The result type is default integer scalar. The result value is the rank of *a*.

Example

If object C is an assumed-rank dummy argument and its associated argument is an array of rank 5, RANK(C) returns the value 5.

If D is an array declared DIMENSION (2, 3, 4), RANK(D) returned the value 3.

Assumed-Rank Specifications

RANSET

Portability Subroutine: *Sets the seed for the random number generator.*

Module

USE IFPORT

Syntax

```
CALL RANSET (seed)
```

seed	(Input) REAL(4). The reset value for the seed.

READ Statement

Statement: *Transfers input data from external sequential, direct-access, or internal records.*

Syntax

Sequential

Formatted:

```
READ (eunit, format [, advance] [, asynchronous] [, blank] [, decimal] [, id] [, pad] [, pos] [, round] [, size] [, iostat] [, err] [, end] [, eor] [, iomsg]) [io-list]
```

```
READ form[, io-list]
```

Formatted - List-Directed:

```
READ (eunit, *[, asynchronous] [, blank] [, decimal] [, id] [, pad] [, pos] [, round] [, size] [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

```
READ *[, io-list]
```

Formatted - Namelist:

```
READ (eunit, nml-group[, asynchronous] [, blank] [, decimal] [, id] [, pad] [, pos] [, round] [, size] [, iostat] [, err] [, end] [, iomsg])
```

```
READ nml
```

Unformatted:

```
READ (eunit [, asynchronous] [, id] [, pos] [, iostat] [, err][, end] [, iomsg]) [io-list]
```

Direct-Access
Formatted:

```
READ (eunit, format, rec [, asynchronous] [, blank] [, decimal] [, id] [, pad] [, pos] [, round] [, size] [, iostat] [, err] [, iomsg]) [io-list]
```

Unformatted:

```
READ (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err] [, iomsg]) [io-list]
```

Internal

```
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

Internal Namelist

```
READ (iunit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

eunit
Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if *eunit* is not the first specifier in the list.

format
Is a format specifier. It is optionally prefaced by FMT= if *format* is the second specifier in the list and the first specifier indicates a logical or internal unit specifier *without* the optional keyword UNIT=.

For internal READs, an asterisk (*) indicates list-directed formatting. For direct-access READs, an asterisk is not permitted.

advance
Is an advance specifier (ADVANCE=*c-expr*). If the value of *c-expr* is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous
Is an asynchronous specifier (ASYNCHRONOUS=*i-expr*). If the value of *i-expr* is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

blank
Is a blank control specifier (BLANK = blnk). If the value of blnk is 'NULL', all blanks are ignored. If the value is 'ZERO', all blanks are treated as zeros. The default value is 'NULL'.

decimal	Is a decimal mode specifier (DECIMAL=*dmode*) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.
id	Is an id specifier (ID=*id-var*). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.
pad	Is a blank pading specifier (PAD = pd). If the value of pad is 'YES', the record will be padded with blanks when necessary. If the value is 'NO', the record will not be padded with blanks. The default value is 'YES'.
pos	Is a pos specifier (POS=*p*) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified for a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.
round	Is a rounding specifier (ROUND=*rmode*) that determines the I/O rounding mode for this READ statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.
size	Is a character count specifier (SIZE=*i-var*).
iostat	Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.
err, end, eor	Are branch specifiers if an error (ERR=*label*), end-of-file (END=*label*), or end-of-record (EOR=*label*) condition occurs. EOR can only be specified for nonadvancing READ statements.
iomsg	Is an I/O message specifier (IOMSG=*msg-var*).
io-list	Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list. If an item in *io-list* is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as *eunit*. If I/O is to or from a formatted device, *io-list* cannot contain derived-type variables, but it can contain components of derived types. If I/O is to a binary or unformatted device, *io-list* can contain either derived type components or a derived type variable.
form	Is the nonkeyword form of a format specifier (no FMT=).
*	Is the format specifier indicating list-directed formatting. (It can also be specified as FMT=*.)
nml-group	Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if *nml-group* is not the second I/O specifier. For more information, see Namelist Specifier.

nml	Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist I/O.
rec	Is the cell number of a record to be accessed directly. It must be prefaced by REC=.
iunit	Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if *iunit* is not the first specifier in the list. It must be a character variable. It must not be an array section with a vector subscript.

If you specify EOR= or SIZE=, you must also specify ASYNCHRONOUS='NO'.

If you specify BLANK=, DECIMAL=, PAD=, or ROUND=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Caution
The READ statement can disrupt the results of certain graphics text functions (such as SETTEXTWINDOW) that alter the location of the cursor. You can avoid the problem by getting keyboard input with the GETCHARQQ function and echoing the keystrokes to the screen using OUTTEXT. Alternatively, you can use SETTEXTPOSITION to control cursor location.

Example

```
DIMENSION ia(10,20)
! Read in the bounds for the array.
! Then read in the array in nested implied-DO lists
! with input format of 8 columns of width 5 each.
READ (6, 990) il, jl, ((ia(i,j), j = 1, jl), i =1, il)
990 FORMAT (2I5, /, (8I5))

! Internal read gives a variable string-represented numbers
CHARACTER*12 str
str = '123456'
READ (str,'(i6)') i

! List-directed read uses no specified format
REAL x, y
INTEGER i, j
READ (*,*) x, y, i, j
```

REAL Directive

General Compiler Directive: *Specifies the default real kind.*

Syntax

```
!DIR$ REAL:{ 4 | 8 | 16 }
```

The REAL directive selects a size of 4 (KIND=4), 8 (KIND=8), or 16 (KIND=16) bytes for default real numbers. When the directive is in effect, all default real and complex variables are of the kind specified in the directive. Only numbers specified or implied as REAL without KIND are affected.

The REAL directive can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. REAL cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

Example

```
REAL r              ! a 4-byte REAL
WRITE(*,*) KIND(r)
CALL REAL8( )
WRITE(*,*) KIND(r)  ! still a 4-byte REAL
                    !   not affected by setting in subroutine
END
SUBROUTINE REAL8( )
  !DIR$ REAL:8
  REAL s ! an 8-byte REAL
  WRITE(*,*) KIND(s)
END SUBROUTINE
```

Syntax Rules for Compiler Directives

REAL Function

Elemental Intrinsic Function (Generic): *Converts a value to real type.*

Syntax

```
result = REAL (a[,kind])
```

a	(Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is real. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of *a* as follows:

- If *a* is integer or real, the result is equal to an approximation of *a*. If *a* is complex, the result is equal to an approximation of the real part of *a*.

- If *a* is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of *a* as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by *a* is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by *a* is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.
  - If a binary, octal, or hexadecimal literal constant is truncated as an argument to intrinsic function REAL, the discarded bits must all be zero.

Specific Name [1]	Argument Type	Result Type
	INTEGER(1)	REAL(4)
FLOATI	INTEGER(2)	REAL(4)
FLOAT [2, 3]	INTEGER(4)	REAL(4)
REAL [2]	INTEGER(4)	REAL(4)
FLOATK	INTEGER(8)	REAL(4)
	REAL(4)	REAL(4)
SNGL [2, 4]	REAL(8)	REAL(4)
SNGLQ	REAL(16)	REAL(4)
	COMPLEX(4)	REAL(4)
	COMPLEX(8)	REAL(8)

[1] These specific functions cannot be passed as actual arguments.

[2]The setting of compiler options specifying real size can affect FLOAT, REAL, and SNGL.

[3] Or FLOATJ. For compatibility with older versions of Fortran, FLOAT is generic, allowing any kind of INTEGER argument, and returning a default real result.

[4] For compatibility with older versions of Fortran, SNGL is generic, allowing any kind of REAL argument, and returning a default real result.

If the argument is a a binary, octal, or hexadecimal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

Example

REAL (-4) has the value -4.0.

REAL (Y) has the same kind parameter and value as the real part of complex variable Y.

If C is complex, C%RE is the same as REAL (C).

REAL Statement

Statement: *Specifies the REAL data type.*

Syntax

```
REAL
REAL([KIND=] n)
REAL* n
DOUBLE PRECISION
```

n Is a constant expression that evaluates to kind 4, 8 or 16.

Description

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

REAL(4) and REAL*4 (single precision) are the same data type. REAL(8), REAL*8, and DOUBLE PRECISION are the same data type.

Example

```
! type declarations with attribute specifiers
REAL (8), PARAMETER :: testval=50.d0
REAL, SAVE :: a(10), b(20,30)
REAL, PARAMETER :: x = 100.

! attribute statements to declare the same entities
REAL x, a, b, testval*8
DIMENSION a(10), b(20,30)
SAVE a, b
PARAMETER (x = 100., testval=50.d0)
```

Model for Real Data

RECORD

Statement: *Declares a record structure as an entity with a name.*

Syntax

```
RECORD /structure-name/record-namelist [, /structure-name/record-namelist]...
```

structure-name	Is the name of a previously declared structure.
record-namelist	Is a list of one or more variable names, array names, or array specifications, separated by commas. All of the records named in this list have the same structure and are allocated separately in memory.

You can use record names in COMMON and DIMENSION statements, but not in DATA or NAMELIST statements.

Records initially have undefined values unless you have defined their values in structure declarations.

STRUCTURE and RECORD constructs have been replaced by derived types, which should be used in writing new code. See Derived Data Types.

Example

```
STRUCTURE /address/
  LOGICAL*2    house_or_apt
  INTEGER*2    apt
  INTEGER*2    housenumber
  CHARACTER*30 street
  CHARACTER*20 city
  CHARACTER*2  state
  INTEGER*4    zip
END STRUCTURE

RECORD /address/ mailing_addr(20), shipping_addr(20)
```

The following shows another example:

```
RECORD /T1/ a, b, /T2/ c, /T3/ d, e, f
```

RECURSIVE and NON_RECURSIVE

Keywords: *RECURSIVE specifies that a subroutine or function can call itself directly or indirectly. NON_RECURSIVE specifies that a subroutine or function does not call itself directly or indirectly.*

Description

RECURSIVE or NON_RECURSIVE can be specified once in a FUNCTION or SUBROUTINE statement. They cannot both appear in the same statement.

Procedures not specified as RECURSIVE or NON_RECURSIVE are currently compiled as NON_RECURSIVE.

The default behavior can be changed by using the `-assume [no]recursion` option, the `standard-semantics` option, or in an OPTIONS statement.

NOTE
The Fortran 2018 Standard specifies that the default mode is recursion; previous standards specified the default was no recursion. The default compilation mode will change to recursion in a future release.

If a function is directly recursive and array valued, and if the keyword RESULT is not specified in the FUNCTION statement, the result variable is the function name, and all occurrences of the function name in the executable part of the function are references to the function result variable.

A directly recursive function cannot have a declared type of CHARACTER if the character length is declared as *.

A procedure interface is always explicit within the subprogram that defines the procedure.

The keyword RECURSIVE *must* be specified if the compilation mode is not set to recursive by a compiler option and if any of the following applies (directly or indirectly):

- The subprogram invokes itself.
- The subprogram invokes a subprogram defined by an ENTRY statement in the same subprogram.
- An ENTRY procedure in the same subprogram invokes one of the following:
  - Itself
  - Another ENTRY procedure in the same subprogram
  - The subprogram defined by the FUNCTION or SUBROUTINE statement

The keyword NON_RECURSIVE must be specified if the compilation mode is set to recursion by a compiler option and the procedure is not to be compiled for recursion.

Example

```
! RECURS.F90
!
  i = 0
  CALL Inc (i)
  END
  RECURSIVE SUBROUTINE Inc (i)
  i = i + 1
  CALL Out (i)
  IF (i.LT.20) CALL Inc (i)    ! This also works in OUT
  END SUBROUTINE Inc

  SUBROUTINE Out (i)
  WRITE (*,*) i
  END SUBROUTINE Out
```

REDUCE

Transformational Intrinsic Function (Generic):
Performs general array reduction.

Syntax

```
result = REDUCE (array, operation [, mask] [, identity] [, ordered])
result = REDUCE (array, operation, dim [, mask] [, identity] [, ordered])
```

array	(Input) Must be an array of any data type.
operation	(Input) Must be a pure function with two non-optional, scalar, nonallocatable, nonpointer, nonpolymorphic dummy arguments with the same declared type and type-parameters as *array*. If one argument has the ASYNCHRONOUS, TARGET, or VALUE attribute, the other argument must have the same attribute. The function result must be non-polymorphic and scalar, with the same declared type and type parameters as *array*. The function should implement a mathematically associated operation; it need not be commutative.
dim	(Input) Must be a scalar integer whose value is greater than or equal to 1 and less than or equal to the rank of *array*.
mask	(Input; optional) Must be of type logical and conformable with *array*.
identity	(Input; optional) Must be scalar with the same declared type and type parameters as *array*.
ordered	(Input; optional) Must be a scalar of type logical.

Results

The result has the same declared type and type parameters as *array*. If *dim* does not appear the result is scalar; otherwise if n=RANK (array) the result has shape [d_1, d_2,...d_{dim-1}, d_{dim+1},...d_n] and rank n−1.

The result value is calculated differently depending on the form of the call:

1. The result of REDUCE (array, operation [, identity, ordered]) is calculated iteratively over the values of *array*. The initial order of the sequence is array element order. While there is more than one element in the sequence, each iteration calculates r = operation (a, b) replacing a and b with r.

   If ordered is present with the value .true., a and b must be the first two elements of the sequence. The process continues until the sequence has one value, and that is the value of the reduction. If *array* is a zero-sized array and identity is present, the result is the value of identity; otherwise error termination is initiated.
2. The result of REDUCE(array, operation, mask [, identity, ordered] is calculated as for case 1, but the sequence of values consists only of those values of array for which the corresponding element of mask has the value .true..
3. If *array* is a rank 1 array, REDUCE (array, operation, dim [, mask, identity, ordered) is equivalent to REDUCE (array, operation [, mask, identity, ordered]); otherwise, the value of element (s_1, s_2,..., s_{dim-1},s_{dim+1},..., s_n) of REDUCE (array, operation, dim [, mask, identity, ordered] is equal to REDUCE (array (s_1, s_2,..., s_{dim-1}, :, s_{dim+1},..., s_n), operation, dim = 1 [, mask(s_1, s_2,..., s_{dim-1}, :, s_{dim+1},..., s_n), identity, ordered]).

Example

The following examples all use the function my_add, which returns the sum of its two real arguments.

1. The result of REDUCE ([2.0, 4.0, 6.0], my_add) is 12.0.
2. REDUCE (array, my_add, mask = array < 0.0, identity = 0.0) returns the sum of the negative elements of array, or 0.0 if array is zero sized or all of arrays elements are non-negative.
3. If array is declared as

```
REAL,DIMENSION(2, 3)  :: array = [1.0, 2.0, 3.0, 4.0, 5.0, 6.0]
```

then REDUCE (array, my_add, DIM = 2) has the result [5.0, 7.0, 9.0] and REDUCE (array, my_add, DIM = 1) has the result [6.0, 15.0].

REDUCTION

Parallel Directive Clause: *Performs a reduction operation on the specified variables.*

Syntax

`REDUCTION ([`*`reduction-modifier`*`, ]`*`reduction-identifier`*` : `*`list`*`)`

reduction-modifier	Is INSCAN, TASK, or DEFAULT.
reduction-identifier	Is an identifier, user defined operator, or generic name which has appeared in an accessible DECLARE REDUCTION directive, or one of the predefined reduction operators or intrinsic names in the table of predefined *reduction-identifier*s below.
list	Is the name of one or more variables that are accessible to the scoping unit. Each *list* item must be definable. Each name must be separated by a comma. The type of each variable must be compatible with a type for which the *reduction-identifier* has an accessible definition. Assumed-size arrays, procedure pointers, and dummy arguments that are pointers with the INTENT (IN) attribute are not allowed. Array sections are allowed. For each list item, the number of copies is unspecified. The same list item cannot appear in both a REDUCTION and an IN_REDUCTION clause in the same directive.

If a *reduction-modifier* is not present or if DEFAULT is specified for PARALLEL, LOOP, and worksharing constructs, one or more copies of each reduction *list* item is created for each implicit task in the region as if the *list* item had been specified in a PRIVATE clause.

If the REDUCTION clause appears in a SIMD statement, one or more private copies of each reduction *list* item is created for each SIMD lane. If the REDUCTION clause is in a TASKLOOP directive, private copies of reduction *list* items are created as if a PRIVATE clause had been specified containing the *list* item. For a REDUCTION clause in a TEAMS construct, one or more private copies of each reduction *list* item are created for the initial task of each team in the league.

The TASK *reduction-modifier* can only appear in a REDUCTION clause of a PARALLEL or worksharing construct or in a combined construct for which one of these constructs is a constituent member and the SIMD and LOOP construct are *not* constituent members. If the TASK *reduction-modifier* is specified for a PARALLEL or worksharing construct, it is as if each reduction *list* item appeared in a PRIVATE clause in the directive, and any number of additional private copies can be created to support task reductions. If the TASK *reduction-modifier* appears in a REDUCTION clause, a NOWAIT clause cannot appear for the same construct.

List items in a REDUCTION clause of the inner most enclosing worksharing or PARALLEL construct must not be accessed in an explicit task generated by a construct unless that construct contains an IN_REDUCTION clause that contains the same list items.

The INSCAN *reduction-modifier* is allowed only in a worksharing construct, a SIMD construct, or a composite construct for which these constructs are a constituent construct, and the DISTRIBUTE is not a constituent construct. It indicates that in each iteration of the loop, a scan computation is performed over the updates to each list item. Each list item is made PRIVATE in the construct. Upon completion of the region, the value of the private copy of a list item from the last logical iteration of the loops of the construct is assigned to the original list item.

Each *list* item of a REDUCTION clause with the INSCAN *reduction-modifier* must appear as a list item in an INCLUSIVE or EXCLUSIVE clause in a SCAN directive contained in the loop (nest) enclosed in the construct. If INSCAN appears in one REDUCTION clause of a construct, all REDUCTION clauses of that construct must contain an INSCAN *reduction-modifier*. If an INSCAN *reduction-modifier* is applied to a construct that is combined with a TARGET construct, it is as if each list item also appears in a MAP clause with a *map-type* of TOFROM.

Variables that appear in a REDUCTION clause must be SHARED in the enclosing context. A private copy of each variable in *list* is created for each thread as if the PRIVATE clause had been used. The private copy is initialized according to the *initializer-clause* of the *reduction-identifier*. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a REDUCTION clause.

At the end of the REDUCTION, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the *combiner* specified for the *reduction-identifier*. Reduction operations should all be associative (except for subtraction), and the compiler can freely reassociate the computation of the final value; the partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the construct containing the REDUCTION clause.

However, if the REDUCTION clause is used in a construct to which NOWAIT is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all the threads complete the REDUCTION clause.

Any *list* item copies associated with the reduction must be initialized before they are accessed by the tasks participating in the reduction. After the end of the region, the original *list* item contains the result of the reduction.

An original *list* item with the POINTER attribute, or any pointer component of an original *list* item that is referenced, must be associated at entry to the construct that contains the REDUCTION clause. Also, the *list* item, or the pointer component of the *list* item, must not be deallocated, allocated, or pointer assigned within the region.

An original *list* item with the ALLOCATABLE attribute, or any allocatable component of an original *list* item that is referenced, must be in the allocated state at entry to the construct that contains the REDUCTION clause. Also, the *list* item, or the allocatable component of the *list* item, must be neither deallocated nor allocated within the region.

Any number of REDUCTION clauses can be specified on the directive, but a *list* item can appear only once in REDUCTION clauses for that directive.

If a *list* item is an array section, the following applies:

- The array section must specify contiguous storage and it cannot be a zero-length array section.
- Accesses to the elements of the array outside the specified array section result in unspecified behavior.
- The reduction clause will be applied to each separate element of the array section.
- Access to the elements of the array outside the specified array section result in unspecified behavior.

The following table lists predefined *reduction-identifier*s. These *reduction-identifier*s are implicitly defined and cannot be redefined in a DECLARE REDUCTION directive for the types shown here. The actual initialization value will be consistent with the data type of the reduction variable.

Predefined *reduction-identifiers*

reduction-identifier	Type	Combiner	Initializer
+	INTEGER, REAL, COMPLEX	omp_out = omp_out + omp_in	omp_priv = 0

reduction-identifier	Type	Combiner	Initializer
*	INTEGER, REAL, COMPLEX	omp_out = omp_out * omp_in	omp_priv = 1
-	INTEGER, REAL, COMPLEX	omp_out = omp_out + omp_in	omp_priv = 0
.AND.	LOGICAL	omp_out = omp_out .AND. omp_in	omp_priv = .TRUE.
.OR.	LOGICAL	omp_out = omp_out .OR. omp_in	omp_priv = .FALSE.
.EQV.	LOGICAL	omp_out = omp_out .EQV. omp_in	omp_priv = .TRUE.
.NEQV.	LOGICAL	omp_out = omp_out .NEQV. omp_in	omp_priv = .FALSE.
MAX	INTEGER, REAL	omp_out = max (omp_out, omp_in)	omp_priv =Smallest representable number
MIN	INTEGER, REAL	omp_out = min (omp_out, omp_in)	omp_priv = Largest representable number
IAND	INTEGER	omp_out = iand (omp_out, omp_in)	omp_priv = All bits set
IOR	INTEGER	omp_out = ior (omp_out, omp_in)	omp_priv = 0
IEOR	INTEGER	omp_out = ieor (omp_out, omp_in)	omp_priv = 0

If a directive allows REDUCTION clauses, the number you can specify is not limited. However, each variable name can appear only once in only one of the clauses.

NOTE
If a variable appears in a REDUCTION clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a *map-type* of TOFROM.

Example

In the following program fragment, time will be the sum of the time spent in the do loop across all threads:

```
  use omp_lib
  integer i
  double precision t1, time
  call omp_set_num_threads(4)
  ...
!$omp do reduction(+:time)
  do i = 1, omp_get_num_threads()
    t1 = omp_get_wtime()
    ...
    time = omp_get_wtime() - t1
```

```
end do
!here time is equal to the total time across all threads
...
```

%REF

Built-in Function: *Changes the form of an actual argument. Passes the argument by reference. In Intel® Fortran, passing by reference is the default.*

Syntax

`%REF (a)`

a (Input) An expression, record name, procedure name, array, character array section, or array element.

You must specify %REF in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following table lists the Intel® Fortran defaults for argument passing, and the allowed uses of %REF:

Actual Argument Data Type	Default	%REF
Expressions:		
Logical	REF	Yes
Integer	REF	Yes
REAL(4)	REF	Yes
REAL(8)	REF	Yes
REAL(16)	REF	Yes
COMPLEX(4)	REF	Yes
COMPLEX(8)	REF	Yes
COMPLEX(16)	REF	Yes
Character	See table note [1]	Yes
Hollerith	REF	No
Aggregate[2]	REF	Yes
Derived	REF	Yes
Array Name:		
Numeric	REF	Yes

Actual Argument Data Type	Default	%REF
Character	See table note [1]	Yes
Aggregate[2]	REF	Yes
Derived	REF	Yes
Procedure Name:		
Numeric	REF	Yes
Character	See table note [1]	Yes

[1]A character argument is passed by address and hidden length.

[2]In Intel® Fortran record structures

The %REF and %VAL functions override related !DIR$ ATTRIBUTE settings.

Example

```
CHARACTER(LEN=10) A, B
CALL SUB(A, %REF(B))
```

Variable A is passed by address and hidden length. Variable B is passed by reference.

Note that on Windows* systems, compiler option `iface` determines how the character argument for variable B is passed.

%VAL
%LOC
/iface compiler option

RENAME

Portability Function: *Renames a file.*

Module

USE IFPORT

Syntax

`result = RENAME (from,to)`

from	(Input) Character*(*). Path of an existing file.
to	(Input) Character*(*). The new path for the file (see Caution note below).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

- EACCES - The file or directory specified by *to* could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
- ENOENT - The file or path specified by *from* could not be found.
- EXDEV - Attempt to move a file to a different device.

Caution
This routine can cause data to be lost. If the file specified in *to* already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.

The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).

Example

```
use IFPORT
integer(4) istatus
character*12 old_name, new_name
print *, "Enter file to rename: "
read *, old_name
print *, "Enter new name: "
read *, new_name
ISTATUS = RENAME (old_name, new_name)
```

See Also
RENAMEFILEQQ

RENAMEFILEQQ
Portability Function: *Renames a file or directory.*

Module
USE IFPORT

Syntax
`result = RENAMEFILEQQ (oldname,newname)`

oldname	(Input) Character*(*). Current name of the file or directory to be renamed.
newname	(Input) Character*(*). New name of the file or directory.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the *newname* parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$ACCES - Permission denied. The file's or directory's permission setting does not allow the specified access.
- ERR$EXIST - The file or directory already exists.
- ERR$NOENT - File or directory or path specified by *oldname* not found.
- ERR$XDEV - Attempt to move a file or directory to a different device.

Example

```
USE IFPORT
USE IFCORE
INTEGER(4) len
CHARACTER(80) oldname, newname
```

```
LOGICAL(4) result

WRITE(*,'(A, \)') ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,'(A, \)') ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END
```

See Also

FINDFILEQQ
RENAME
GETLASTERRORQQ

REPEAT

Transformational Intrinsic Function (Generic): *Concatenates several copies of a string.*

Syntax

`result = REPEAT (string,ncopies)`

string	(Input) Must be scalar and of type character.
ncopies	(Input) Must be scalar and of type integer. It must not be negative.

Results

The result is a scalar of type character and length *ncopies* x LEN(*string*). The kind parameter is the same as *string*. The value of the result is the concatenation of *ncopies* copies of *string*.

Example

REPEAT ('S', 3) has the value SSS.

REPEAT ('ABC', 0) has the value of a zero-length string.

The following shows another example:

```
CHARACTER(6) str
str = REPEAT('HO', 3)  ! returns HOHOHO
```

SPREAD

REQUIRES

OpenMP* Fortran Compiler Directive: *Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.*

Syntax

`!$OMP REQUIRES [clause[[,] clause]... ]`

clause	Is one or more of the following: • ATOMIC_DEFAULT_MEM_ORDER (SEQ_CST | ACQ_REL | RELAXED)

Specifies the default memory ordering behavior that an implementation must support for ATOMIC constructs.

If more than one REQUIRES directive contains an ATOMIC_DEFAULT_MEM_ORDER clause, each REQUIRES directive in the same compilation unit that specifies ATOMIC_DEFAULT_MEM_ORDER must specify the same parameter for that clause.

When this clause is specified, it must appear lexically prior to any ATOMIC construct that does not contain a memory order clause.

For information about settings SEQ_CST, ACQ_REL, and RELAXED, see the ATOMIC construct.

- DYNAMIC_ALLOCATORS

  Tells the compiler that the USES_ALLOCATORS clause is optional in TARGET constructs that use allocators in the corresponding TARGET regions.

  If DYNAMIC_ALLOCATORS are supported:

  - Calls to OMP_INIT_ALLOCATOR and OMP_DESTROY_ALLOCATOR are permitted in TARGET regions.
  - Default allocators can be used by ALLOCATE directives and clauses, and in the OMP_ALLOC routines in TARGET regions.
- UNIFIED_ADDRESS

  Tells the compiler that all devices available through OpenMP* directives and API procedures must have a unified address space.

  A pointer to this address space will refer to the same memory location when referenced from all available devices. OpenMP* mechanisms returning device pointers, return device addresses supporting pointer arithmetic.

  When this clause is specified, the IS_DEVICE_POINTER clause is not needed to obtain device addresses from device pointers for use in TARGET regions.

  Host device pointers can be passed as device pointer arguments to device memory procedures, and device pointers can be passed as host pointer arguments to device procedures. A non-host device may have discreet memory. In this case, referencing a host pointer on such a device or referencing a device pointer on the host will result in unspecified behavior.

  Memory local to a specific execution context may be exempt from the UNIFIED_ADDRESS requirements. It may adhere to the requirements of locality to a given thread, contention group, or execution context.
- UNIFIED_SHARED_MEMORY

  This clause implies the UNIFIED_ADDRESS clause. It also causes memory addresses to be accessible to threads on all available devices, with the exception of memory that is local to a specific execution context as described in UNIFIED_ADDRESS.

  All device addresses referring to memory allocated through OpenMP* device memory routines are valid host pointers that may be dereferenced.

If UNIFIED_SHARED_MEMORY is supported:

- The MAP clause in TARGET constructs is optional.
- The DECLARE TARGET directive is optional for static variables accessed in procedures to which a DECLARE TARGET directive is applied.

By default, scalar variables are FIRSTPRIVATE inside TARGET constructs.

A value stored to memory by one device may not be visible to another device until the two devices have synchronized, or both devices synchronize with the host.

Only one occurrence of each clause is permitted in the REQUIRES directive. At least one clause is required.

The REQUIRES directive identifies the requirements needed for execution of the code in the compilation unit in which the directive appears.

The REQUIRES directive must appear in the specification part of the program unit, lexically following all USE, IMPORT, and IMPLICIT statements.

The clauses specified in the REQUIRES directive are added to the requires trait in the OpenMP* context for all points in the compilation unit.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

RESHAPE

Transformational Intrinsic Function (Generic):
Constructs an array with a different shape from the argument array.

Syntax

```
result = RESHAPE (source,shape[,pad] [,order])
```

source — (Input) Must be an array. It may be of any data type. It supplies the elements for the result array. Its size must be greater than or equal to PRODUCT(*shape*) if *pad* is omitted or has size zero.

shape — (Input) Must be an integer array of up to 31 elements, with rank one and constant size. It defines the shape of the result array. Its size must be positive; its elements must not have negative values.

pad — (Input; optional) Must be an array with the same type and kind parameters as *source*. It is used to fill in extra values if the result array is larger than *source*.

order — (Input; optional) Must be an integer array with the same shape as *shape*. Its elements must be a permutation of (1,2,...,n), where n is the size of *shape*. If *order* is omitted, it is assumed to be (1,2,...,n).

Results

The result is an array of shape *shape* with the same type and kind parameters as *source*. The size of the result is the product of the values of the elements of *shape*.

In the result array, the array elements of *source* are placed in the order of dimensions specified by *order*. If *order* is omitted, the array elements are placed in normal array element order.

The array elements of *source* are followed (if necessary) by the array elements of *pad* in array element order. If necessary, additional copies of *pad* follow until all the elements of the result array have values.

NOTE
In standard Fortran array element order, the first dimension varies fastest. For example, element order in a two-dimensional array would be (1,1), (2,1), (3,1) and so on. In a three-dimensional array, each dimension having two elements, the array element order would be (1,1,1), (2, 1, 1), (1, 2, 1), (2, 2, 1), (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2).

RESHAPE can be used to reorder a Fortran array to match C array ordering before the array is passed from a Fortran to a C procedure.

Example

RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 3/)) has the value

```
 [ 3  5  7 ]
 [ 4  6  8 ].
```

RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 4/), (/1, 1/), (/2, 1/)) has the value

```
 [ 3  4  5  6 ]
 [ 7  8  1  1 ].
```

The following shows another example:

```
INTEGER AR1( 2, 5)
REAL F(5,3,8)
REAL C(8,3,5)
AR1 = RESHAPE((/1,2,3,4,5,6/),(/2,5/),(/0,0/),(/2,1/))
! returns      1 2 3 4 5
!              6 0 0 0 0
!
! Change Fortran array order to C array order
C = RESHAPE(F, (/8,3,5/), ORDER = (/3, 2, 1/))
END
```

RESULT

Keyword: *Specifies a name for a function result.*

Description

Normally, a function result is returned in the function's name, and all references to the function name are references to the function result.

However, if you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. In this case, all references to the function name are recursive calls, and the function name must not appear in specification statements.

The RESULT name must be different from the name of the function.

Example

The following shows an example of a recursive function specifying a RESULT variable:

```
RECURSIVE FUNCTION FACTORIAL(P) RESULT(L)
  INTEGER, INTENT(IN) :: P
  INTEGER L
  IF (P == 1) THEN
    L = 1
  ELSE
    L = P * FACTORIAL(P - 1)
  END IF
END FUNCTION
```

The following shows another example:

```
 recursive function FindSame(Aindex,Last,Used) &
&  result(FindSameResult)
 type(card) Last
 integer Aindex, i
 logical matched, used(5), FindSameResult
 if( Aindex > 5 ) then
   FindSameResult = .true.
   return
 endif
 ...
```

Program Units and Procedures

RETURN

Statement: *Transfers control from a subprogram to the calling program unit.*

Syntax

RETURN [*expr*]

expr	Is a scalar expression that is converted to an integer value if necessary. The *expr* is only allowed in subroutines; it indicates an alternate return. (An alternate return is an obsolescent feature in Standard Fortran.)

Description

When a RETURN statement is executed in a function subprogram, control is transferred to the referencing statement in the calling program unit.

When a RETURN statement is executed in a subroutine subprogram, control is transferred to the first executable statement following the CALL statement that invoked the subroutine, or to the alternate return (if one is specified).

Example

The following shows how alternate returns can be used in a subroutine:

```
   CALL CHECK(A, B, *10, *20, C)
   ...
10 ...
20 ...
   SUBROUTINE CHECK(X, Y, *, *, C)
   ...
50   IF (X) 60, 70, 80
60   RETURN
70   RETURN 1
80   RETURN 2
   END
```

The value of X determines the return, as follows:

- If X < 0, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the calling program.
- If X = = 0, the first alternate return (RETURN 1) occurs and control is transferred to the statement identified with label 10.
- If X > 0, the second alternate return (RETURN 2) occurs and control is transferred to the statement identified with label 20.

Note that an asterisk (*) specifies the alternate return. An ampersand (&) can also specify an alternate return in a CALL statement, but not in a subroutine's dummy argument list.

The following shows another example:

```
    SUBROUTINE Loop
    CHARACTER in
10  READ (*, '(A)') in
    IF (in .EQ. 'Y') RETURN
    GOTO 10
!   RETURN implied by the following statement:
    END

! The following example shows alternate returns:
    CALL AltRet (i, *10, *20, *30)
    WRITE (*, *) 'normal return'
    GOTO 40
10  WRITE (*, *) 'I = 10'
    GOTO 40
20  WRITE (*, *) 'I = 20'
    GOTO 40
30  WRITE (*, *) 'I = 30'
40  CONTINUE
    END
    SUBROUTINE AltRet (i, *, *, *)
    IF (i .EQ. 10) RETURN 1
    IF (i .EQ. 20) RETURN 2
    IF (i .EQ. 30) RETURN 3
    END
```

In the above example, RETURN 1 specifies the list's first alternate-return label, which is a symbol for the actual argument *10 in the CALL statement. RETURN 2 specifies the second alternate-return label, and RETURN 3 specifies the third alternate-return label.

See Also

CALL

CASE

REWIND

Statement: *Positions a sequential or direct access file at the beginning of the file (the initial point). It takes one of the following forms:*

Syntax

```
REWIND ([UNIT=] io-unit[, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])

REWIND io-unit
```

io-unit	(Input) Is an external unit specifier.
label	Is the label of the branch target statement that receives control if an error occurs.
msg-var	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
i-var	(Output)Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The unit number must refer to a file on disk or magnetic tape, and the file must be open for sequential, direct, or append access.

If a REWIND is done on a direct access file, the NEXTREC specifier is assigned a value of 1.

If a file is already positioned at the initial point, a REWIND statement has no effect.

If a REWIND statement is specified for a unit that is not open, it has no effect.

Example

The following statement repositions the file connected to I/O unit 3 to the beginning of the file:

```
REWIND 3
```

Consider the following statement:

```
REWIND (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 at the beginning of the file. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

The following shows another example:

```
WRITE (7, '(I10)') int
REWIND (7)
READ (7, '(I10)') int
```

See Also

OPEN
READ
WRITE
Data Transfer I/O Statements
Branch Specifiers

REWRITE

Statement: *Rewrites the current record.*

Syntax

Formatted:

```
REWRITE (eunit, format[, iostat] [, err]) [io-list]
```

Unformatted:

```
REWRITE (eunit[, iostat][ , err]) [io-list]
```

eunit	Is an external unit specifier ([UNIT=]io-unit).
format	Is a format specifier ([FMT=]format).
iostat	Is a status specifier (IOSTAT=i-var).
err	Is a branch specifier (ERR=label) if an error condition occurs.
io-list	Is an I/O list.

Description

In the REWRITE statement, data (translated if formatted; untranslated if unformatted) is written to the current (existing) record in a file with direct access.

The current record is the last record accessed by a preceding, successful sequential or direct-access READ statement.

Between a READ and REWRITE statement, you should not specify any other I/O statement (except INQUIRE) on that logical unit. Execution of any other I/O statement on the logical unit destroys the current-record context and causes the current record to become undefined.

Only one record can be rewritten in a single REWRITE statement operation.

The output list (and format specification, if any) must not specify more characters for a record than the record size. (Record size is specified by RECLin an OPEN statement.)

If the number of characters specified by the I/O list (and format, if any) do not fill a record, blank characters are added to fill the record.

Example

In the following example, the current record (contained in the relative organization file connected to logical unit 3) is updated with the values represented by NAME, AGE, and BIRTH:

```
      REWRITE (3, 10, ERR=99) NAME, ,AGE, BIRTH
10    FORMAT (A16, I2, A8)
```

RINDEX

Portability Function: *Locates the index of the last occurrence of a substring within a string.*

Module

USE IFPORT

Syntax

```
result = RINDEX (string,substr)
```

string	(Input) Character*(*). Original string to search.
substr	(Input) Character*(*). String to search for.

Results

The result type is INTEGER(4). The result is the starting position of the final occurrence of *substrg* in *string*. The result is zero if *substring* does not occur in *string*.

Example

```
USE IFPORT
character*80 mainstring
character*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring,shortstr)
! where is 19
```

See Also

INDEX

RNUM

Elemental Intrinsic Function (Specific): *Converts a character string to a REAL(4) value. This function cannot be passed as an actual argument.*

Syntax

```
result = RNUM (i)
```

i (Input) Must be of type character.

Results

The result type is REAL(4). The result value is the real value represented by the character string *i*.

Example

RNUM ("821.003") has the value 821.003 of type REAL(4).

RRSPACING

Elemental Intrinsic Function (Generic): *Returns the reciprocal of the relative spacing of model numbers near the argument value.*

Syntax

```
result = RRSPACING (x)
```

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*. The result has the value $|x^* b^{-e}| \times b^{p}$. Parameters *b*, *e*, *p* are defined in Model for Real Data.

Example

If -3.0 is a REAL(4) value, RRSPACING (-3.0) has the value 0.75×2^{24}.

The following shows another example:

```
REAL(4) res4
REAL(8) res8, r2
res4 = RRSPACING(3.0)  ! returns 1.258291E+07
```

```
res4 = RRSPACING(-3.0) ! returns 1.258291E+07
r2 = 487923.3
res8 = RRSPACING(r2)   ! returns 8.382458680573952E+015
END
```

See Also

SPACING

Data Representation Models

RSHIFT

Elemental Intrinsic Function (Generic): *Shifts the bits in an integer right by a specified number of positions. This is the same as specifying ISHFT with a negative shift.*

See Also

See ISHFT.

RTC

Portability Function: *Returns the number of seconds elapsed since a specific Greenwich mean time.*

Module

USE IFPORT

Syntax

```
result = RTC( )
```

Results

The result type is REAL(8). The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

Example

```
USE IFPORT
real(8) s, s1, time_spent
INTEGER(4) i, j
s = RTC( )
call sleep(4)
s1 = RTC( )
time_spent = s1 - s
PRINT *, 'It took ',time_spent, 'seconds to run.'
```

See Also

DATE_AND_TIME

TIME portability routine

RUNQQ

Portability Function: *Executes another program and waits for it to complete.*

Module

USE IFPORT

Syntax

`result = RUNQQ (filename,commandline)`

filename	(Input) Character*(*). File name of a program to be executed.
commandline	(Input) Character*(*). Command-line arguments passed to the program to be executed.

Results

The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the exit code of that program is returned to the program that launched it. If the program fails, -1 is returned.

The RUNQQ function executes a new process for the operating system using the same path, environment, and resources as the process that launched it. The launching process is suspended until execution of the launched process is complete.

Example

```
USE IFPORT
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END
```

See also the example in NARGS.

S

This section describes language features that start with S.

S

SAME_TYPE_AS

Inquiry Intrinsic Function (Generic): *Inquires whether the dynamic type of one object is the same as the dynamic type of another object.*

Syntax

`result = SAME_TYPE_AS (a , b)`

a	(Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.
b	(Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.

Results

The result type is default logical scalar. The result is true only if the dynamic type of *a* is the same as the dynamic type of *b*.

SAVE

Statement and Attribute: *Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.*

Syntax

The SAVE attribute can be specified in a type declaration statement or a SAVE statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] SAVE [, *att-ls*] :: *entity*[, *entity*] ...

Statement:

SAVE [[::]*entity* [, *entity*] ...]

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
entity	Is the name of an object, the name of a procedure pointer, or the name of a common block enclosed in slashes (/*common-block-name*/).

Description

In Intel® Fortran, certain variables are given the SAVE attribute, or not, by default. Variables are implicitly given the SAVE attribute depending on whether a program unit is compiled for recursion.

> **NOTE**
> In the following lists, "initialized" means that the variable has been given an initial value in a DATA statement, it has been initialized in a type declaration statement, it is of a derived type that is default initialized, or it has a component that is default initialized.

The following variables are *not* saved by default:

- Scalar variables that are local to a recursive procedure and are not initialized (see above Note)
- Arrays of any type that are local to a recursive procedure and are not initialized (see above Note)
- Variables that are declared AUTOMATIC
- Local variables with the ALLOCATABLE attribute

The following variables are saved by default:

- Variables in COMMON blocks
- Scalar variables not of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that are local to a non-recursive subprogram
- Non-scalar local variables of non-recursive subprograms
- Module or submodule variables
- Initialized (see above Note) variables
- RECORD variables that are data initialized by default initialization specified in its STRUCTURE declaration

Local variables that are not described in the preceding two lists are saved by default.

> **NOTE**
> Certain compiler options (such as options `[Q]save`, `assume norecursion`, and `auto`) and the use of OpenMP* features can change the defaults.

NOTE
Coarrays that do not have the ALLOCATABLE attribute and are local to the main program unit or to a procedure are not statically allocated, but are allocated at program startup. They are not deallocated until the program terminates.

To enhance portability and avoid possible compiler warning messages, Intel recommends that you use the SAVE statement to name variables whose values you want to preserve between subprogram invocations.

When a SAVE statement does not explicitly contain a list, all allowable items in the scoping unit are saved.

A SAVE statement cannot specify the following (their values cannot be saved):

- A blank common
- An object in a common block
- A procedure
- A dummy argument
- A function result
- An automatic object
- A PARAMETER (named) constant

Even though a common block can be included in a SAVE statement, individual variables within the common block can become undefined (or redefined) in another scoping unit.

If a common block is saved in any scoping unit of a program (other than the main program), it must be saved in every scoping unit in which the common block appears.

A SAVE statement has no effect in a main program.

Example

The following example shows a type declaration statement specifying the SAVE attribute:

```
SUBROUTINE TEST()
  REAL, SAVE :: X, Y
```

The following is an example of the SAVE statement:

```
SAVE A, /BLOCK_B/, C, /BLOCK_D/, E
```

The following shows another example:

```
  SUBROUTINE MySub
    COMMON /z/ da, in, a, idum(10)
    real(8) x,y
    ...

    SAVE x, y, /z/
! alternate declaration
    REAL(8), SAVE :: x, y
    SAVE /z/
```

SCALE

Elemental Intrinsic Function (Generic): *Returns the value of the exponent part (of the model for the argument) changed by a specified value.*

Syntax

```
result = SCALE (x,i)
```

x	(Input) Must be of type real.
i	(Input) Must be of type integer.

Results

The result type and kind are the same as *x*. The result has the value *x* x b ^{i}. Parameter *b* is defined in Model for Real Data.

Example

If 3.0 is a REAL(4) value, SCALE (3.0, 2) has the value 12.0 and SCALE (3.0, 3) has the value 24.0.

The following shows another example:

```
REAL r
r = SCALE(5.2, 2)     ! returns 20.8
```

SCAN Directive

OpenMP* Fortran Compiler Directive: *Specifies a scan computation that updates each list item in each iteration of the loop.*

Syntax

```
loop-associated-directive
do-loop-headers
   block
   !$OMP SCAN clause
   block
do-termination-statements
[end-loop-associated-directive]
```

loop-associated-directive	Is a SIMD or TARGET SIMD directive.
do-loop-headers	Is one or more Fortran DO statements.
block	Is a structured block (section) of statements or constructs.
clause	Is one of the following: • INCLUSIVE (*list*) • EXCLUSIVE (*list*)

	If an INCLUSIVE clause appears, an inclusive scan computation is performed for each *list* item in the clause. If an EXCLUSIVE clause appears, an exclusive scan computation is performed for each *list* item in the clause.
do-termination-statements	Is one or more Fortran DO-loop terminal statements, such as END DO, CONTINUE, or a terminal statement for a nonblock DO construct.
end-loop-associated-directive	Is an optional END SIMD or END TARGET SIMD directive.

The SCAN directive can appear in the body of a loop or loop nest that is in a worksharing construct, a worksharing-loop SIMD, or a SIMD construct.

There are two phases for each iteration of a SCAN loop, as follows:

- The input phase

  For each iteration of an INCLUSIVE scan loop, the statements that appear lexically prior to the SCAN directive constitute the input phase.

  For each iteration, except the last iteration of an EXCLUSIVE scan loop, the statements that lexically precede the directive constitute the input phase.
- The scan phase

  For each iteration of an INCLUSIVE scan loop, the statements that follow the directive constitute the scan phase.

  For each iteration, except the last iteration of an EXCLUSIVE scan loop, the statements that lexically follow the directive constitute the scan phase.

The last loop iteration does not have an input phase. For this iteration, all statements lexically preceding and following the directive constitute the scan phase. All computations that update a list item during an iteration are contained in the input phase. A statement that references a list item in the scan phase uses the result of the scan operation for that iteration.

For a given iteration, the result of a scan operation is calculated according to the last generalized prefixed sum ($PRESUM_{last}$) applied to the sequence of values given by the original value of the list item upon entry of the loop construct, and updated values given the list item in each of the iterations of the loop. The $PRESUM_{last}$ (*op*, a_1, . . . a_n) is defined for a binary operation *op* and a sequence of N values a_1, . . . a_n as follows:

- If N = 1, a_1
- If N > 1, *op* ($PRESUM_{last}$ (*op*, a_1, . . . a_k), $PRESUM_{last}$ (*op*, a_{k+1}, . . . a_n)) where 1 <= K <= N

At the beginning of the input phase for each iteration, the list item is initialized with the initializer value of the *reduction-identifier* specified by the REDUCTION clause on the innermost enclosing OpenMP* construct. For a given iteration, the update value of a list item is the value of the list item upon completion of the iteration's input phase.

If *orig_value* is the initial value of a list item upon entry to a worksharing-loop, worksharing SIMD, or SIMD construct, if *combiner* is the combiner for the *reduction-identifier* specified in the REDUCTION clause on the construct, and *update-value*$_i$ is the value for the list item for iteration i, then at the beginning of the scan phase of the first iteration, a list item of an INCLUSIVE clause on a SCAN directive is assigned the result of the operation $PRESUM_{last}$ (*combiner*, *orig_value*, *update-value*$_1$ . . . *update-value*$_i$). At the beginning of the scan phase of the first iteration, a list item of an EXCLUSIVE clause on a SCAN directive is assigned the value *orig_value*. At the beginning of the scan phase of each subsequent iteration, i > 1, a list item of an EXCLUSIVE clause on a SCAN directive is the result of the operation $PRESUM_{last}$ (*combiner*, *orig_value*, *update-value*$_1$ . . . *update-value*$_{i-1}$).

A worksharing-loop, worksharing-loop SIMD, or a SIMD construct that has a REDUCTION clause with the INSCAN modifier must contain exactly one SCAN directive in the loop body of the construct, and a list item in an INCLUSIVE or EXCLUSIVE clause must be a list item in the REDUCTION clause of the construct.

With the exception of dependencies for list items in the INCLUSIVE or EXCLUSIVE clause, cross-iteration dependencies across loop iterations are not permitted. Except for INCLUSIVE or EXCLUSIVE clause list-item dependencies, intra-iteration dependencies between a statement lexically preceding the SCAN directive and a statement lexically following a SCAN directive are not permitted.

In ifort, SCAN directives are only supported in SIMD construct directives.

In ifx, SCAN directives are supported in SIMD and TARGET SIMD construct directives.

Example

The following contains an inclusive and an exclusive scan SIMD loop:

```
real,dimension(10)   :: a, b
real                 :: s
integer              :: i
...

do i = 1, 10
  a(i) = real (i)
end do
s = 0.0
! Inclusive scan
!$omp simd reduction (inscan, +:s)
do i = 1, 10
  s    = s + a(i)
  !$omp scan inclusive (s)
  b(i) = s
end do
print *, b

s = 0.0
! Exclusive scan
!$omp simd reduction (inscan, +:s)
do i = 1, 10
  b(i) = s
  !$omp scan exclusive (s)
  s    = s + a(i)
end do
print *, b
```

The first print statement prints the sequence 1.0 3.0 6.0 10.0 15.0 21.0 28.0 36.0 45.0 55.0. The second print statement prints the sequence 0.0 1.0 3.0 6.0 10.0 15.0 21.0 28.0 36.0 45.0.

SCAN Function

Elemental Intrinsic Function (Generic): *Scans a string for any character in a set of characters.*

Syntax

`result = SCAN (`*`string`*`, `*`set`*` [, `*`back`*`] [, `*`kind`*`])`

string	(Input) Must be of type character.
set	(Input) Must be of type character with the same kind parameter as *string*.
back	(Input; optional) Must be of type logical.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *back* is omitted (or is present with the value false) and *string* has at least one character that is in *set*, the value of the result is the position of the leftmost character of *string* that is in *set*.

If *back* is present with the value true and *string* has at least one character that is in *set*, the value of the result is the position of the rightmost character of *string* that is in *set*.

If no character of *string* is in *set* or the length of *string* or *set* is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

Example

SCAN ('ASTRING', 'ST') has the value 2.

SCAN ('ASTRING', 'ST', BACK=.TRUE.) has the value 3.

SCAN ('ASTRING', 'CD') has the value zero.

The following shows another example:

```
INTEGER i
INTEGER array(2)
i = SCAN ('FORTRAN', 'TR')                 ! returns 3
i = SCAN ('FORTRAN', 'TR', BACK = .TRUE.)  ! returns 5
i = SCAN ('FORTRAN', 'GHA')                ! returns 6
i = SCAN ('FORTRAN', 'ora')                ! returns 0
array = SCAN ((/'FORTRAN','VISUALC'/),(/'A', 'A'/))
                                     ! returns (6, 5)

! Note that when using SCAN with arrays, the string
! elements must be the same length. When using string
! constants, blank pad to make strings the same length.
! For example:

array = SCAN ((/'FORTRAN','MASM '/),(/'A', 'A'/))
                                     ! returns (6, 2)
END
```

VERIFY

SCANENV

Portability Subroutine: *Scans the environment for the value of an environment variable.*

Module

USE IFPORT

Syntax

```
CALL SCANENV (envname,envtext,envvalue)
```

envname	(Input) Character*(*). Contains the name of an environment variable you need to find the value for.
envtext	(Output) Character*(*). Set to the full text of the environment variable if found, or to ' ' if nothing is found.
envvalue	(Output) Character*(*). Set to the value associated with the environment variable if found or to ' ' if nothing is found.
	SCANENV scans for an environment variable that matches *envname* and returns the value or string it is set to.

SCOPE

OpenMP* Fortran Compiler Directive: *Specifies a block of code to be executed by all threads in a team; it may contain additional OpenMP constructs. This feature is only available for ifx.*

Syntax

```
!$OMP SCOPE [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END SCOPE [NOWAIT]
-or-
!$OMP SCOPE [clause[[,] clause]... ]
   strictly-structured-block
!$OMP END SCOPE [NOWAIT]
```

clause	Is one or more of the following: • ALLOCATE • NOWAIT • PRIVATE (list) • REDUCTION ([reduction-modifier,]reduction-identifier : list)
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

Description

The binding thread set for the SCOPE region is the current team.

The SCOPE region binds to the innermost parallel region in which it is enclosed. All threads of a team that execute the binding parallel region, and only those threads, execute the statements of the block. The block may contain additional OpenMP constructs.

If NOWAIT is not specified, the participating threads execute an implicit barrier at the end of the SCOPE block.

Example

The following code performs a reduction on the array `arr`. Each thread produces a sum of the elements dispatched to it. The SCOPE directive is used to perform a reduction of each partial sum. The sum of the array, and the number of threads that participate, is printed.

```
SUBROUTINE sum_reduce (arr)
  IMPLICIT NONE
  REAL,DIMENSION(:)  :: arr
  REAL               :: sum = 0.0, partial_sum = 0.0
  INTEGER            :: i, num_threads = 0
  !$omp PARALLEL FIRSTPRIVATE (partial_sum), SHARED (num_threads, arr)
    !$omp DO
      DO i = 1, SIZE (arr)
        partial_sum = partial_sum + arr(i)
      END DO
    !$omp END DO
    !$omp SCOPE reduction (+ : sum, num_threads)
      sum = sum + partial sum
      num_threads = num_threads + 1
    !$omp END SCOPE
  !$omp END PARALLEL
  PRINT *, "sum of arr = ", sum, " number of threads participating = ", num_threads
  RETURN
END SUBROUTINE
```

SCWRQQ

Portability Subroutine: *Returns the floating-point processor control word.*

Module

USE IFPORT

Syntax

`CALL SCWRQQ (control)`

control	(Output) INTEGER(2). Floating-point processor control word.

SCRWQQ performs the same function as the runtime subroutine GETCONTROLFPQQ, and is provided for compatibility.

Example

See the example in LCWRQQ.

See Also

GETCONTROLFPQQ
LCWRQQ

SECNDS Intrinsic Procedure

Elemental Intrinsic Function (Generic): *Provides the system time of day, or elapsed time, as a floating-point value in seconds. SECNDS can be used as an intrinsic function or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.*

Syntax

This function must not be passed as an actual argument. It is not a pure function, so it cannot be referenced inside a FORALL construct.

```
result = SECNDS (x)
```

x	(Input) Must be of type real.

Results

The result type and kind are the same as *x*.

If *x* is zero, the result value is the time in seconds since the most recent midnight (in local time).

If *x* is not zero, it is compared to *now*: the value that would be returned if *x* had been zero. If *x* is less than *now*, then the result value is *now* - *x*. If *x* is more than *now*, the function assumes that *x* is the result of a call to SECONDS made the previous day and returns the value between that time and *now*.

This function cannot detect a delay of more than one day between calls. For timing intervals longer than 24 hours, use DCLOCK.

This function does not account for daylight savings changes in either direction.

The value of SECNDS is accurate to 0.01 second, which is the resolution of the system clock.

The 24 bits of precision provide accuracy to the resolution of the system clock for about one day. However, loss of significance can occur if you attempt to compute very small elapsed times late in the day.

Example

The following shows how to use SECNDS to perform elapsed-time computations:

```
C     START OF TIMED SEQUENCE
      T1 = SECNDS(0.0)

C     CODE TO BE TIMED
      ...
      DELTA = SECNDS(T1)      ! DELTA gives the elapsed time
```

DATE_AND_TIME

RTC

SYSTEM_CLOCK

TIME intrinsic procedure

SECNDS portability routine

DCLOCK

SECNDS Portability Routine

Portability Function: *Returns the number of seconds that have elapsed since midnight, less the value of its argument. SECNDS can be used as a portability function or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.*

Module

USE IFPORT

Syntax

```
result = SECNDS (time)
```

time	(Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.

Results

The result type is REAL(4). The result value is the number of seconds that have elapsed since midnight, minus *time*, with a precision of a hundredth of a second (0.01).

To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

Example

```
USE IFPORT
REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
   J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ',s, 'seconds to run.'
```

SECTIONS

OpenMP* Fortran Compiler Directive: *Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.*

Syntax

```
!$OMP SECTIONS [clause[[,] clause] ... ]
[!$OMP SECTION]
```

```
   block
[!$OMP SECTION
   block]...
!$OMP END SECTIONS[NOWAIT]
```

clause	Is one of the following: • ALLOCATE ([allocator :] list) • FIRSTPRIVATE (list) • LASTPRIVATE ([CONDITIONAL:] list) • NOWAIT • PRIVATE (list) • REDUCTION ([reduction-modifier,]reduction-identifier : list)
block	Is a structured block (section) of statements or constructs. Any constituent section must also be a structured block. You cannot branch into or out of the block.

The binding thread set for a SECTIONS construct is the current team. A SECTIONS region binds to the innermost enclosing parallel region.

Each section of code is preceded by a SECTION directive, although the directive is optional for the first section. The SECTION directives must appear within the lexical extent of the SECTIONS and END SECTIONS directive pair.

The last section ends at the END SECTIONS directive. Threads that complete execution of their SECTIONs encounter an implied barrier at the END SECTIONS directive unless a NOWAIT clause appears or the NOWAIT keyword is specified in the END SECTIONS directive.

SECTIONS directives must be encountered by all threads in a team or by none at all.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```
  !$OMP PARALLEL
  !$OMP SECTIONS
  !$OMP SECTION
        CALL XAXIS
  !$OMP SECTION
        CALL YAXIS
  !$OMP SECTION
        CALL ZAXIS
  !$OMP END SECTIONS
  !$OMP END PARALLEL
```

Parallel Processing Model for information about Binding Sets

SEED

Portability Subroutine: *Changes the starting point of the pseudorandom number generator.*

Module

USE IFPORT

Syntax

CALL SEED (*iseed*)

iseed (Input) INTEGER(4). Starting point for RANDOM.

SEED uses *iseed* to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.

This routine is not thread-safe.

Example

```
USE IFPORT
REAL myrand
CALL SEED(7531)
CALL RANDOM(myrand)
```

See Also

RANDOM
RANDOM_INIT

RANDOM_SEED
RANDOM_NUMBER

SELECT CASE and END SELECT

Statement: *Transfers program control to a selected block of statements according to the value of a controlling expression.*

Example

```
CHARACTER*1 cmdchar
. . .
Files: SELECT CASE (cmdchar)
  CASE ('0')
    WRITE (*, *) "Must retrieve one to nine files"
  CASE ('1':'9')
    CALL RetrieveNumFiles (cmdchar)
  CASE ('A', 'a')
    CALL AddEntry
  CASE ('D', 'd')
    CALL DeleteEntry
  CASE ('H', 'h')
    CALL Help
  CASE DEFAULT
    WRITE (*, *) "Command not recognized; please re-enter"
END SELECT Files
```

See Also

See CASE.

SELECT RANK

Statement: *Marks the beginning of a SELECT RANK construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the rank of an assumed-rank variable.*

Syntax

```
[name:] SELECT RANK ([ assoc-name => ] selector)
  [rank-case-stmt
    block]...
END SELECT [name]
```

name	(Optional) Is the name of the SELECT RANK construct.
assoc-name	(Optional) Is an identifier that becomes associated with the *selector*. It becomes the associating entity. The identifier name must be unique within the construct. If unspecified, the associate name for the construct is *selector*.
selector	Is the name of an assumed-rank array.
rank-case-stmt	(Optional) Is one of the following: • RANK (*scalar-int-const-expr*) [*name*] • RANK (*) [*name*] • RANK DEFAULT [*name*] The *scalar-int-const-expr* must be non-negative. The same rank value can only be specified in one *rank-case-stmt*. RANK DEFAULT and RANK (*) can be specified only once in the construct. RANK (*) cannot be specified if *selector* has the ALLOCATABLE or POINTER attribute.
block	(Optional) Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of a SELECT RANK statement, the same name must appear in the corresponding END SELECT statement. If a *rank-case-stmt* specifies a construct name, the corresponding SELECT RANK statement must specify the same name. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT RANK statement, you cannot specify one following the END SELECT statement or any corresponding *rank-case-stmt*.

If no other *rank-case-stmt* of the construct matches the *selector*, a RANK DEFAULT statement, if present, identifies the block of code to be executed.

A SELECT RANK construct selects at most one *block* to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector.

The following steps determine which block is selected for execution:

1. If the *selector* is argument associated with an assumed-size array, a RANK (*) statement identifies the block to be executed.
2. If the *selector* is *not* argument associated with an assumed-size array, a RANK (*scalar-int-const-exp*) statement identifies the block to be executed if the *selector* has that rank.
3. Otherwise, if there is a RANK DEFAULT statement, the block following that statement is executed.

A branch is allowed from within a block of a SELECT RANK construct to the END SELECT statement. Branches to the END SELECT from outside the construct are not allowed.

The associating entity in the block following a RANK DEFAULT statement is assumed rank and has the same attributes as the *selector*; it can used only in contexts that an assumed-rank entity can be used. The associating entity in the block following a RANK (*) statement is an assumed-size one dimensional array and lower bound 1, as if declared DIMENSION(1:*).

The associating entity in the block following a RANK (*scalar-int-const-exp*) statement has the rank specified. The lower bound is the lower bound of the *selector* for each corresponding dimension, and the upper bound is the upper bound of the *selector* for each corresponding dimension of the *selector*. The associating entity in a RANK(*) or a RANK (*scalar-int-const-exp*) block is a variable and may appear in variable definition contexts.

If the *selector* has the POINTER, TARGET or ALLOCATABLE attribute, the associating entity has the same attributes.

Example

The following example shows a SELECT RANK construct that initializes scalars, rank 1, and rank 2 arrays to zero. If the dummy argument rank is greater than 2, an error message is printed.

```
SUBROUTINE INITIALIZE (ARG)
  REAL :: ARG(..)
  SELECT RANK (ARG)
    RANK (0)   ! Scalar
      ARG = 0.0
    RANK (1)
      ARG(:) = 0.0
    RANK (2)
      ARG(:, :) = 0.0
    RANK DEFAULT
      PRINT *, "Subroutine initialize called with unexpected rank argument"
  END SELECT
  RETURN
END SUBROUTINE
```

The following example shows how to use a select rank to initialize assumed-size arrays of any rank to zero:

```
SUBROUTINE INITIALIZE (ARG, SIZE)
  REAL,CONTIGUOUS :: ARG(..)
  INTEGER         :: SIZE, I
  SELECT RANK (ARG)
    RANK (0)   ! Special case the scalar case
      ARG = 0.0
    RANK (*)
      DO I = 1, SIZE
        ARG(I) = 0.0
      END DO
  END SELECT
  RETURN
END SUBROUTINE
```

See Also

Construct Association

SELECT TYPE

Statement: *Marks the beginning of a SELECT TYPE construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the dynamic type of a specified expression.*

Syntax

```
[name:] SELECT TYPE ([ assoc-name => ] selector)
  [type-guard-stmt
    block]...
END SELECT [name]
```

name	(Optional) Is the name of the SELECT TYPE construct.
assoc-name	(Optional) Is an identifier that becomes associated with the *selector*. It becomes the associating entity. The identifier name must be unique within the construct. If selector is not a named variable, *assoc-name* => must appear.
selector	Is an expression or variable. It must be polymorphic. It is evaluated when the SELECT TYPE statement is executed.
type-guard-stmt	(Optional) Is one of the following: • TYPE IS (*type*) [*name*] • CLASS IS (*derived-type*) [*name*] • CLASS DEFAULT [*name*] CLASS DEFAULT can be specified only once in the construct. The same type and kind parameter values can only be specified in one TYPE IS statement and one CLASS IS statement.
type	Is an intrinsic type specifier or a derived-type specifier. It must specify that each length type parameter is assumed. It cannot be a sequence derived type or a type with the BIND attribute.
defived-type	The same as *type*, but it cannot be an intrinsic type specifier.
block	(Optional) Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of a SELECT TYPE statement, the same name must appear in the corresponding END SELECT statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT TYPE statement, you cannot specify one following the END SELECT statement or any *type-guard-stmt*. If a *type-guard-stmt* specifies a construct name, it must match the construct name on the corresponding SELECT TYPE statement.

A branch to the END SELECT statement is allowed from within the SELECT TYPE construct, but it is not allowed from anywhere outside the construct.

Execution of a SELECT TYPE construct whose selector is not a variable causes the selector expression to be evaluated.

A SELECT TYPE construct selects at most one block to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector. The entity associated with the associate name has the declared type and type parameters of the selector. The entity is polymorphic only if the selector is polymorphic.

The following steps determine which block is selected for execution:

1. If a TYPE IS statement matches the selector, the block following that statement is executed. A TYPE IS statement matches the selector if the dynamic type and type parameter values of the selector are the same as those specified by the statement.

2. Otherwise, if exactly one CLASS IS statement matches the selector, the block following that statement is executed. A CLASS IS statement matches the selector if the dynamic type of the selector is an extension of the type specified by the statement and the kind type parameters specified by the statement are the same as the corresponding type parameters of the dynamic type of the selector.
3. Otherwise, if several CLASS IS statements match the selector, one of these statements must specify a type that is an extension of all the types specified in the others. In this case, the block following that statement is executed.
4. Otherwise, if there is a CLASS DEFAULT statement, the block following that statement is executed.

Within the block following a TYPE IS statement, the associating entity is not polymorphic, it has the type named in the TYPE IS statement, and has the type parameters of the selector.

Within the block following a CLASS IS statement, the associating entity is polymorphic and has the declared type named in the CLASS IS statement. The type parameters of the associating entity are the corresponding type parameters of the selector.

Within the block following a CLASS DEFAULT statement, the associating entity is polymorphic and has the same declared type as the selector. The type parameters of the associating entity are those of the declared type of the selector.

If the declared type of the selector is M, specifying CLASS DEFAULT has the same effect as specifying CLASS IS (M).

A *type-guard-stmt* cannot be a branch target statement. You can branch to an END SELECT statement only from within its SELECT TYPE construct.

Example

The following example shows a SELECT TYPE construct:

```
TYPE POINT
   REAL :: X, Y
END TYPE POINT
TYPE, EXTENDS(POINT) :: POINT_3D
   REAL :: Z
END TYPE POINT_3D
TYPE, EXTENDS(POINT) :: COLOR_POINT
   INTEGER :: COLOR
END TYPE COLOR_POINT

TYPE(POINT), TARGET :: P
TYPE(POINT_3D), TARGET :: P3D
TYPE(COLOR_POINT), TARGET :: CP
CLASS(POINT), POINTER :: P_OR_CP
P_OR_CP=> CP
SELECT TYPE ( AN => P_OR_CP )
CLASS IS ( POINT )
                  ! "CLASS ( POINT ) :: AN" is implied here
   PRINT *, AN%X, AN%Y     ! This block gets executed
TYPE IS ( POINT_3D )
                  ! "TYPE ( POINT_3D ) :: AN" is implied here
   PRINT *, AN%X, AN%Y, AN%Z
END SELECT
```

The following example uses declarations from the above example, but it omits the associate name AN:

```
P_OR_CP => P3D
SELECT TYPE ( P_OR_CP )
CLASS IS ( POINT )
                  ! "CLASS ( POINT ) :: P_OR_CP" is implied here
   PRINT *, P_OR_CP%X, P_OR_CP%Y
```

```
TYPE IS ( POINT_3D )
                  ! "TYPE ( POINT_3D ) :: P_OR_CP" is implied here
   PRINT *, P_OR_CP%X, P_OR_CP%Y, P_OR_CP%Z    ! This block gets executed
END SELECT
```

Additional Attributes Of Associate Names

SELECTED_CHAR_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind type parameter of the character set named by the argument.

Syntax

```
result = SELECTED_CHAR_KIND(name)
```

name	(Input) Must be scalar and of type default character. Its value must be 'DEFAULT' or 'ASCII'.

Results

The result is a scalar of type default integer.

The result is a scalar of type default integer. The result value is 1 if NAME has the value 'DEFAULT' or 'ASCII'; otherwise, the result value is -1.

SELECTED_INT_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of an integer data type.

Syntax

```
result = SELECTED_INT_KIND (r)
```

r	(Input) Must be scalar and of type integer.

Results

The result is a scalar of type default integer. The result has a value equal to the value of the kind parameter of the integer data type that represents all values *n* in the range of values *n* with $-10^r < n < 10^r$.

If no such kind type parameter is available on the processor, the result is -1. If more than one kind type parameter meets the criteria, the value returned is the one with the smallest decimal exponent range. For more information, see Model for Integer Data.

Example

SELECTED_INT_KIND (6) = 4

The following shows another example:

```
i = SELECTED_INT_KIND(8)  ! returns 4
i = SELECTED_INT_KIND(3)  ! returns 2
i = SELECTED_INT_KIND(10) ! returns 8
i = SELECTED_INT_KIND(20) ! returns -1 because 10**20
                          !   is bigger than 2**63
```

See Also

SELECTED_REAL_KIND

SELECTED_REAL_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of a real data type.

Syntax

```
result = SELECTED_REAL_KIND ([p] [,r] [,radix])
```

`p`	(Input; optional) Must be scalar and of type integer.
`r`	(Input; optional) Must be scalar and of type integer.
`radix`	(Input; optional) Must be scalar and of type integer.

At least argument `p` or `r` must be present.

Results

If `p` or `r` is absent, the result is as if the argument was present with the value zero. If `radix` is absent, there is no requirement on the radix of the selected kind.

The result is a scalar of type default integer. If both arguments are absent, the result is zero. Otherwise, the result has a value equal to a value of the kind parameter of a real data type with decimal precision, as returned by the function PRECISION, of at least `p` digits, a decimal exponent range, as returned by the function RANGE, of at least `r`, and a radix, as returned by the function RADIX, of `radix`.

If no such kind type parameter is available on the processor, the result is as follows:

```
-1 if the precision is not available but the range is available
-2 if the exponent range is not available but the precision is available
-3 if neither is available
-4 if real types for the precision and the range are available separately but not together
-5 if no real type of the specified radix is available
```

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision. Intel® Fortran currently does not return -4 for any combination of `p` and `r`, and supports only a radix of 2. For more information, see Model for Real Data.

Example

SELECTED_REAL_KIND (6, 70) = 8

The following shows another example:

```
i = SELECTED_REAL_KIND(r=200, radix=2)  ! returns 8
i = SELECTED_REAL_KIND(13)     ! returns 8
i = SELECTED_REAL_KIND (100, 200)  ! returns -1
i = SELECTED_REAL_KIND (13, 5000)  ! returns -2
i = SELECTED_REAL_KIND (100, 5000) ! returns -3
i = SELECTED_REAL_KIND (13, radix=42)  ! returns -5
```

The following example gives a compile-time error:

```
i = SELECTED_REAL_KIND ()
```

SEQUENCE

Statement: *Preserves the storage order of a derived-type definition.*

Syntax

```
SEQUENCE
```

Description

The SEQUENCE statement allows derived types to be used in common blocks and to be equivalenced.

The SEQUENCE statement appears only as part of derived-type definitions. It causes the components of the derived type to be stored in the same sequence they are listed in the type definition. If you do not specify SEQUENCE, the physical storage order is not necessarily the same as the order of components in the type definition.

If a derived type is a sequence derived type, then any other derived type that includes it must also be a sequence type.

Example

```
!DIR$ PACK:1
TYPE NUM1_SEQ
  SEQUENCE
  INTEGER(2)::int_val
  REAL(4)::real_val
  LOGICAL(2)::log_val
END TYPE NUM1_SEQ
TYPE num2_seq
   SEQUENCE
   logical(2)::log_val
   integer(2)::int_val
   real(4)::real_val
end type num2_seq
type (num1_seq) num1
type (num2_seq) num2
character*8 t, t1
equivalence (num1,t)
equivalence (num2,t1)
num1%int_val=2
num1%real_val=3.5
num1%log_val=.TRUE.
t1(1:2)=t(7:8)
t1(3:4)=t(1:2)
t1(5:8)=t(3:6)
print *, num2%int_val, num2%real_val, num2%log_val
end
```

Derived Data Types

Data Types, Constants, and Variables

SETCONTROLFPQQ

Portability Subroutine: *Sets the value of the floating-point processor control word.*

Module

USE IFPORT

Syntax

`CALL SETCONTROLFPQQ (controlword)`

controlword (Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math processor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in `IFPORT.F90`):

Parameter name	Hex value	Description
FPCW$MCW_IC	Z'1000'	**Infinity control mask**
FPCW$AFFINE	Z'1000'	Affine infinity
FPCW$PROJECTIVE	Z'0000'	Projective infinity
FPCW$MCW_PC	Z'0300'	**Precision control mask**
FPCW$64	Z'0300'	64-bit precision
FPCW$53	Z'0200'	53-bit precision
FPCW$24	Z'0000'	24-bit precision
FPCW$MCW_RC	Z'0C00'	**Rounding control mask**
FPCW$CHOP	Z'0C00'	Truncate
FPCW$UP	Z'0800'	Round up
FPCW$DOWN	Z'0400'	Round down
FPCW$NEAR	Z'0000'	Round to nearest
FPCW$MCW_EM	Z'003F'	**Exception mask**
FPCW$INVALID	Z'0001'	Allow invalid numbers
FPCW$DENORMAL	Z'0002'	Allow subnormals (very small numbers)
FPCW$SUBNORMAL	Z'0002'	Allow subnormals (very small numbers)
FPCW$ZERODIVIDE	Z'0004'	Allow divide by zero
FPCW$OVERFLOW	Z'0008'	Allow overflow
FPCW$UNDERFLOW	Z'0010'	Allow underflow
FPCW$INEXACT	Z'0020'	Allow inexact precision

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.

Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.

NOTE
The Intel® Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Intel Fortran with another compiler.

Example

```
USE IFPORT
INTEGER(2) status, control, controlo
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
!     Save old control word
controlo = control
!     Clear all flags
control = control .AND. Z'0000'
!     Set new control to round up
control = control .OR. FPCW$UP
CALL SETCONTROLFPQQ(control)
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END
```

SETDAT
Portability Function: *Sets the system date. This function is only available on Windows* and Linux* systems.*

Module
USE IFPORT

Syntax
`result = SETDAT (iyr, imon, iday)`

iyr	(Input) INTEGER(2) or INTEGER(4). Year (*xxxx*AD).
imon	(Input) INTEGER(2) or INTEGER(4). Month (1-12).
iday	(Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

Results

The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.

Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Refer to your operating system documentation for the range of permitted dates.

NOTE
On Linux systems, you must have root privileges to execute this function.

Example

```
USE IFPORT
LOGICAL(4) success
success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))
END
```

See Also

GETDAT
GETTIM
SETTIM

SETENVQQ

Portability Function: *Sets the value of an existing environment variable, or adds and sets a new environment variable.*

Module

USE IFPORT

Syntax

`result = SETENVQQ (varname=value)`

varname=value	(Input) Character*(*). String containing both the name and the value of the variable to be added or modified. Must be in the form: *varname = value*, where *varname* is the name of an environment variable and *value* is the value being assigned to it.

Results

The result is of type LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate *value* so that trailing blanks are preserved. For example, the string `PATH= `sets *value* to `''`.

You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, LIB= removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the runtime library and not on the environment segment created for the process by the operating system.

SETENVQQ and GETENVQQ will not work properly with the Windows* APIs SetEnvironmentVariable and GetEnvironmentVariable.

Example

```
USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END
```

See Also

GETENVQQ
RUNQQ

SETERRORMODEQQ

Portability Subroutine: *Sets the prompt mode for critical errors that by default generate system prompts.*

Module

USE IFPORT

Syntax

`CALL SETERRORMODEQQ (`*pmode*`)`

pmode	(Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (*pmode*= .TRUE.). You can also enable system error prompts by calling SETERRORMODEQQ with *pmode* set to ERR$HARDPROMPT (defined in `IFPORT.F90`).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting *pmode* to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).

Note that SETERRORMODEQQ affects only errors that generate a system prompt. It does not affect other I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with STATUS='OLD'.

Example

```
!PROGRAM 1
!  DRIVE B door open
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
!  Generates a system prompt error here and waits for the user
!  to respond to the prompt before continuing
100   WRITE(*,*) ' Continuing'
END

! PROGRAM 2
!  DRIVE B door open
 USE IFPORT
 CALL SETERRORMODEQQ(.FALSE.)
 OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
!  Causes the statement at label 100 to execute
!  without system prompt
100   WRITE(*,*) ' Drive B: not available, opening      &
                  &alternative drive.'
 OPEN (10, FILE = 'C:\NOFILE.DAT')
 END
```

SET_EXPONENT

Elemental Intrinsic Function (Generic): *Returns the value of the exponent part (of the model for the argument) set to a specified value.*

Syntax

`result = SET_EXPONENT (x,i)`

x	(Input) Must be of type real.
i	(Input) Must be of type integer.

Results

The result type and kind are the same as *x*. The result has the value *x* x b $^{i-e}$. Parameters *b* and *e* are defined in Model for Real Data. If *x* has the value zero, the result is zero.

Example

If 3.0 is a REAL(4) value, SET_EXPONENT (3.0, 1) has the value 1.5.

See Also

EXPONENT

Data Representation Models

SETFILEACCESSQQ

Portability Function: *Sets the file access mode for a specified file.*

Module

USE IFPORT

Syntax

`result = SETFILEACCESSQQ (filename,access)`

filename (Input) Character*(*). Name of a file to set access for.

access (Input) INTEGER(4). Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such asIOR or OR):

- FILE$ARCHIVE - Marked as having been copied to a backup device.
- FILE$HIDDEN - Hidden. The file does not appear in the directory list that you can request from the command console.
- FILE$NORMAL - No special attributes (default).
- FILE$READONLY - Write-protected. You can read the file, but you cannot make changes to it.
- FILE$SYSTEM - Used by the operating system.

The flags are defined in module `IFPORT.F90`.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

To set the access value for a file, add the constants representing the appropriate access.

Example

```
USE IFPORT
INTEGER(4) permit
LOGICAL(4) result

permit = 0   ! clear permit
permit = IOR(FILE$READONLY, FILE$HIDDEN)
result = SETFILEACCESSQQ ('formula.f90', permit)
END
```

See Also

GETFILEINFOQQ

SETFILETIMEQQ

Portability Function: *Sets the modification time for a specified file.*

Module

USE IFPORT

Syntax

`result = SETFILETIMEQQ (filename,timedate)`

filename (Input) Character*(*). Name of a file.

timedate (Input) INTEGER(4). Time and date information, as packed by PACKTIMEQQ.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of different versions of the file. The process that calls SETFILETIMEQQ must have write access to the file; otherwise, the time cannot be changed. If you set *timedate* to FILE$CURTIME (defined in `IFPORT.F90`), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the following:

- ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- ERR$INVAL - Invalid argument; the *timedate* argument is invalid.
- ERR$MFILE - Too many open files (the file must be opened to change its modification time).
- ERR$NOENT - File or path not found.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

Example

```
USE IFPORT
INTEGER(2) day, month, year
INTEGER(2) hour, minute, second, hund
INTEGER(4) timedate
LOGICAL(4) result

CALL GETDAT(year, month, day)
CALL GETTIM(hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day,    &
                 hour, minute, second)
result = SETFILETIMEQQ('myfile.dat', timedate)
END
```

See Also

PACKTIMEQQ
UNPACKTIMEQQ
GETLASTERRORQQ

SETTIM

Portability Function: *Sets the system time in your programs. This function is only available on Windows* and Linux* systems.*

Module

USE IFPORT

Syntax

`result = SETTIM (ihr, imin, isec, i100th)`

ihr	(Output) INTEGER(4) or INTEGER(2). Hour (0-23).
imin	(Output) INTEGER(4) or INTEGER(2). Minute (0-59).
isec	(Output) INTEGER(4) or INTEGER(2). Second (0-59).
i100th	(Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

Results

The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).

If INTEGER(2) arguments are passed, you must specify USE IFPORT.

> **NOTE**
> On Linux systems, you must have root privileges to execute this function.

Example

```
USE IFPORT
LOGICAL(4) success
success = SETTIM(INT2(21),INT2(53+3),&
                 INT2(14*2),INT2(88))
END
```

GETDAT
GETTIM
SETDAT

SHAPE

Inquiry Intrinsic Function (Generic): *Returns the shape of an array or scalar argument.*

Syntax

`result = SHAPE (source [, kind])`

source	(Input) Is a scalar or array. It may be of any data type. It must not be an assumed-size array, a disassociated pointer, or an allocatable array that is not allocated. It cannot be an assumed-size array.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is a rank-one integer array whose size is equal to the rank of *source*. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is the shape of *source*, unless *source* is assumed-rank and is associated with an assumed-size array. In that case, the last element of the value returned by SHAPE is -1.

The setting of compiler options specifying integer size can affect this function.

Example

SHAPE (2) has the value of a rank-one array of size zero.

If B is declared as B(2:4, -3:1), then SHAPE (B) has the value (3, 5).

The following shows another example:

```
INTEGER VEC(2)
REAL array(3:10, -1:3)
VEC = SHAPE(array)
```

```
WRITE(*,*) VEC ! prints   8       5
END
!
! Check if a mask is conformal with an array
REAL, ALLOCATABLE :: A(:,:,:)
LOGICAL, ALLOCATABLE :: MASK(:,:,:)
INTEGER B(3), C(3)
LOGICAL conform
ALLOCATE (A(5, 4, 3))
ALLOCATE (MASK(3, 4, 5))
! Check if MASK and A allocated. If they are, check
! that they have the same shape (conform).
IF(ALLOCATED(A) .AND. ALLOCATED(MASK)) THEN
  B = SHAPE(A); C = SHAPE(MASK)
  IF ((B(1) .EQ. C(1)) .AND. (B(2) .EQ. C(2))       &
       .AND. (B(3) .EQ. C(3))) THEN
     conform = .TRUE.
  ELSE
     conform = .FALSE.
  END IF
END IF
WRITE(*,*) conform  ! prints F
END
```

See Also

SIZE

SHARED Clause

Parallel Directive Clause: *Specifies variables that will be shared by all the threads in a team.*

Syntax

`SHARED (list)`

list	Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

All threads within a team access the same storage area for SHARED data.

SHIFTA

Elemental Intrinsic Function (Specific): *Performs a right shift with fill. This function cannot be passed as an actual argument.*

Syntax

`result = SHIFTA (i,shift)`

i	(Input) Must be of type integer. This is the value to be shifted.
shift	(Input) Must be of type integer. It must be nonnegative and <= BIT_SIZE(*i*). This value is the number of positions to shift.

Results

The result type and kind are the same as *i*.

The result has the value obtained by shifting the bits of *i* to the right *shift* bits and replicating the leftmost bit of *i* in the left *shift* bits.

If *shift* is zero the result is *i*. Bits shifted off the right end are lost.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

Example

SHIFTA (IBSET (0, BIT_SIZE (0) - 1), 2) is equal to SHIFTL (7, BIT_SIZE (0) - 3).

SHIFTL

Elemental Intrinsic Function (Specific): *Logically shifts an integer left by a specified number of bits.*
This function cannot be passed as an actual argument.

Syntax

`result = SHIFTL (i,shift)`

i	(Input) Must be of type integer. This is the value to be shifted.
shift	(Input) Must be of type integer. The value must be nonnegative and <= BIT_SIZE(*i*). This value is the number of positions to shift.

Results

The result type and kind are the same as *i*. The result is the value of *i* shifted left by *shift* bit positions. Bits shifted off the left end are lost; zeros are shifted in from the opposite end.

SHIFTL (i, j) is the same as ISHFT (i, j).

See Also

ISHFT

SHIFTR

Elemental Intrinsic Function (Specific): *Logically shifts an integer right by a specified number of bits.*
This function cannot be passed as an actual argument.

Syntax

`result = SHIFTR (i,shift)`

i	(Input) Must be of type integer. This is the value to be shifted.
shift	(Input) Must be of type integer. The value must be nonnegative and <= BIT_SIZE(*i*). This value is the number of positions to shift.

Results

The result type and kind are the same as *i*. The result is the value of *i* shifted right by *shift* bit positions. Bits shifted off the right end are lost; zeros are shifted in from the opposite end.

SHIFTR (i, j) is the same as ISHFT (i, -j).

See Also

ISHFT

SHORT

Portability Function: *Converts an INTEGER(4) argument to INTEGER(2) type.*

Module

USE IFPORT

Syntax

`result = SHORT (int4)`

int4	(Input) INTEGER(4). Value to be converted.

Results

The result type is INTEGER(2). The result is equal to the lower 16 bits of *int4*. If the *int4* value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

Example

```
     USE IFPORT
     INTEGER(4) this_one
     INTEGER(2) that_one
     READ(*,*) this_one
     THAT_ONE = SHORT(THIS_ONE)
     WRITE(*,10) THIS_ONE, THAT_ONE
10   FORMAT (X," Long integer: ", I16, " Short integer: ", I16)
     END
```

See Also

INT

Type Declarations

SIGN

Elemental Intrinsic Function (Generic): *Returns the absolute value of the first argument times the sign of the second argument.*

Syntax

`result = SIGN (a, b)`

a	(Input) Must be of type integer or real.
b	(Input) Must have the same type as *a*.

Results

The result type and kind are the same as *a*. The value of the result is as follows:

- | *a* | if *b* > zero and -| *a* | if *b* < zero.
- | *a* | if *b* is of type integer and is zero.
- If *b* is of type real and zero and compiler option `assume minus0` is not specified, the value of the result is | *a* |.
- If *b* is of type real and zero and compiler option `assume minus0` is specified, the processor can distinguish between positive and negative real zero and the following occurs:
  - If *b* is positive real zero, the value of the result is | *a* |.
  - If *b* is negative real zero, the value of the result is -| *a* |.

The specific named versions of the function require that the arguments have the same kind parameters. The generic form of the function permits the kind types of the arguments to differ.

Specific Name	Argument Type	Result Type
BSIGN	INTEGER(1)	INTEGER(1)
IISIGN[1]	INTEGER(2)	INTEGER(2)
ISIGN [2]	INTEGER(4)	INTEGER(4)
KISIGN	INTEGER(8)	INTEGER(8)
SIGN [3]	REAL(4)	REAL(4)
DSIGN [3,4]	REAL(8)	REAL(8)
QSIGN	REAL(16)	REAL(16)

[1] Or HSIGN.

[2] Or JISIGN. For compatibility with older versions of Fortran, ISIGN is treated as a generic function.

[3] The setting of compiler options specifying real size can affect SIGN and DSIGN .

[4] The setting of compiler options specifying double size can affect DSIGN.

Example

SIGN (4.0, -6.0) has the value -4.0.

SIGN (-5.0, 2.0) has the value 5.0.

The following shows another example:

```
c = SIGN (5.2, -3.1)   ! returns -5.2
c = SIGN (-5.2, -3.1)  ! returns -5.2
c = SIGN (-5.2, 3.1)   ! returns  5.2
```

See Also

ABS

assume minus0 compiler option

SIGNAL

Portability Function: *Controls interrupt signal handling and changes the action for a specified signal.*

Module

USE IFPORT

Syntax

`result = SIGNAL (signum, proc, flag)`

signum	(Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names are listed in a table below.
proc	(Input) Name of a signal-handler routine. It must be declared EXTERNAL and INTEGER(4). This routine is called only if *flag* is negative.

flag (Input) INTEGER(4). If negative, the user's *proc* routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the previous value of *proc* associated with the specified signal. For example, if the previous value of *proc* was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is invalid, if the flag value is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINVAL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns -(EINVAL) and a call to IERRNO returns EINVAL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C's signal function, nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

The signal-handler argument *proc* accepts a single INTEGER(4) argument, which is the number of the signal to be handled. The function must use the compiler's default calling conventions. If you have used compiler options, such as option `iface`, to change the default conventions, add the following directive to the signal handler function to reset the calling conventions:

!DIR$ ATTRIBUTES DEFAULT :: *the-routine-specified-in-proc*

The signal-handler function returns an INTEGER(4) value. If the function has handled the signal, the value returned is an integer, but the value is not used.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a runtime operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

- Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
- Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
- Functions that generate a system call (such as TIME).

The following table lists signals, their names and values:

Symbolic name	Number	Description
SIGABRT	6	Abnormal termination
SIGFPE	8	Floating-point error
SIGKILL[1]	9	Kill process
SIGILL	4	Illegal instruction
SIGINT	2	CTRL+C signal
SIGSEGV	11	Illegal storage access
SIGTERM	15	Termination request

[1]SIGKILL can be neither caught nor ignored.

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

Example

```
   USE IFPORT
   EXTERNAL h_abort
   INTEGER(4) :: h_abort
   INTEGER(4) iret1, iret2, procnum
   iret1 = SIGNAL(SIGABRT, h_abort, -1)
   WRITE(*,*) 'Set signal handler #1. Return = ', iret1

   procnum = getpid( )
   iret2 = KILL(procnum, SIGABRT)
   WRITE(*,*) 'Raised signal. Return = ', iret2
   END
!
!  Signal-handler routine
!
   INTEGER(4) FUNCTION h_abort (sig_num)
   INTEGER(4) sig_num
   !DIR$ ATTRIBUTES DEFAULT :: h_abort
   WRITE(*,*) 'In signal handler function h_abort for SIG$ABORT'
   WRITE(*,*) 'signum = ', sig_num
   h_abort = 1
   END
```

See Also

SIGNALQQ

SIGNALQQ

Portability Function: *Registers the function to be called if an interrupt signal occurs.*

Module

USE IFPORT

Syntax

`result = SIGNALQQ (sig,func)`

sig

(Input) INTEGER(4). Interrupt type. One of the following constants, defined in `IFPORT.F90`:

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+CSIGNAL
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

func

(Input) Function to be executed on interrupt. It must be declared EXTERNAL.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a positive integer if successful; otherwise, -1 (SIG$ERR).

SIGNALQQ installs the function *func* as the handler for a signal of the type specified by *sig*. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.

The argument *func* is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

NOTE
All signal-handler functions must be declared with the directive !DIR$ ATTRIBUTES C.

When an interrupt occurs, except a SIG$FPE interrupt, the *sig* argument SIG$INT is passed to *func*, and then *func* is executed.

When a SIG$FPE interrupt occurs, the function *func* is passed two arguments: SIG$FPE and the floating-point error code (for example, FPE$ZERODIVIDE or FPE$OVERFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPE$ and are defined in `IFPORT.F90`.

If *func* returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode.

Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a runtime operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).

To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.

The example below shows a signal handler for SIG$ABORT.

Example

```
!  This program shows a signal handler for
!  SIG$ABORT
USE IFPORT
INTERFACE
  FUNCTION h_abort (signum)
    !DIR$ ATTRIBUTES C :: h_abort
    INTEGER(4) h_abort
    INTEGER(2) signum
  END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret

i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret

i2ret = RAISEQQ(SIG$ABORT)
```

```
WRITE(*,*) 'Raised signal. Return = ', i2ret
END
!
!      Signal handler routine
!
INTEGER(4) FUNCTION h_abort (signum)
  !DIR$ ATTRIBUTES C :: h_abort
  INTEGER(2) signum
  WRITE(*,*) 'In signal handler for SIG$ABORT'
  WRITE(*,*) 'signum = ', signum
  h_abort = 1
END
```

SIMD Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Transforms a loop into a loop that will be executed concurrently using Single Instruction Multiple Data (SIMD) instructions.*

Syntax

```
!$OMP SIMD [clause[[,] clause]... ]
   do-loop
[!$OMP END SIMD]
```

clause

Is one of the following:

- ALIGNED (list [:n])
- `[NO]ASSERT`

  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.
- COLLAPSE (n)
- `EARLY_EXIT`

  Allows vectorization of multiple exit loops. When this clause is specified the following occurs:

  - Each operation before the last lexical early exit of the loop may be executed as if the early exit were not triggered within the SIMD chunk.
  - After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
  - The last value for LINEARs and conditional LASTPRIVATEs are preserved with respect to scalar execution.

  - The last value for REDUCTIONs are computed as if the last iteration in the last SIMD chunk was executed upon exiting the loop.
  - The shared memory state may not be preserved with regard to scalar execution.
  - Exceptions are not allowed.

  When a SIMD loop is specified with the EARLY_EXIT clause, each list item specified in the LINEAR clause is computed based on the last iteration number upon exiting the loop.
- IF ([SIMD:] scalar-logical-expression)
- LASTPRIVATE ([CONDITIONAL:] list)
- LINEAR (linear-list [: linear-modifier [, linear-modifier]])
- `NONTEMPORAL` [(*var1* [, *var2*]...)])

  Directs the compiler to use non-temporal (that is, streaming) stores.

  By default, the compiler automatically determines whether a streaming store should be used for each variable.

  Streaming stores may cause significant performance improvements over non-streaming stores for large trip-count loops on certain processors. However, the misuse of streaming stores can significantly degrade performance.

  A variable cannot appear more than once in a NONTEMPORAL clause, and it cannot appear in more than one NONTEMPORAL clause.
- ORDER ([order-modifier :] CONCURRENT) (ifx only)
- PRIVATE (list)
- REDUCTION ([reduction-modifier,]reduction-identifier : list)
- `SAFELEN`(*m*)

  Limits the number of iterations in a SIMD chunk (set of concurrent iterations).

  The *m* must be a constant positive integer expression; it indicates the number of iterations allowed in a SIMD chunk.

  When this clause is used, no two iterations executed concurrently with SIMD instructions can have a greater distance in the logical iteration space than *m*.

  The number of iterations that are executed concurrently at any given time is defined by the implementation. Each concurrent iteration is executed by a different SIMD vector lane.

  At most one SAFELEN clause can appear in a SIMD directive.
- `SIMDLEN`(*n*)

  Specifies the preferred number of iterations to be executed concurrently. *n* must be a positive scalar integer constant. The number of iterations that are executed concurrently at any given time is implementation defined. Each concurrent iteration will be executed by a different SIMD lane.

  If both SIMDLEN (*n*) and SAFELEN (*m*) are specified, the value of the *n* must be less than or equal to the value of *m*.

At most one SIMDLEN clause can appear in a SIMD directive.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a SIMD directive.

A SIMD construct binds to the current task region. The binding thread set of the SIMD region is the current team.

If used, the END SIMD directive must appear immediately after the end of the loop. If you do not specify an END SIMD directive, an END SIMD directive is assumed at the end of *do-loop*. The SIMD directive is a pure directive, so it can appear in a Fortran PURE procedure.

The SIMD construct enables the execution of multiple iterations of the associated loops concurrently by means of SIMD instructions. No other OpenMP* Fortran construct can appear in a SIMD directive.

A SIMD region binds to the current task region. The binding thread set of the SIMD region is the current team.

When any thread encounters a SIMD construct, the iterations of the loop associated with the construct may be executed concurrently using the SIMD lanes that are available to the thread.

If an ORDERED directive with the SIMD clause is specified inside the SIMD region, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

Example

The following is an example using the SIMD directive:

```
subroutine subr(a, b, c, n)
  implicit none
  real(kind=kind(0.0d0)),dimension(*) :: a, b, c
  integer                             :: n, i

  !$omp simd
    do i = 1, n
      a(i) = a(i) * b(i) + c(i)
    end do

 end subroutine
```

The following example demonstrates the EARLY_EXIT clause:

```
!$omp simd early_exit
  do i = 1, n
     if (a(i) == i) exit
  enddo
```

SIMD Loop Directive

General Compiler Directive: *Requires and controls SIMD vectorization of loops. This directive is deprecated and will be removed in a future release.This feature is only available for ifort.*

Syntax

```
!DIR$ SIMD [clause[[,] clause]...]
```

clause

Is an optional vectorization clause. It can be one or more of the following:

- `[NO]ASSERT`

  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.
- `FIRSTPRIVATE`(*list*)

  list — Is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, each variable has its initial value broadcast to all private instances for each iteration upon entering the SIMD loop.

  A variable in a FIRSTPRIVATE clause can appear in a LASTPRIVATE clause.

  A variable in a FIRSTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.
- `LASTPRIVATE` (*list*)

  list — Is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable).

  A variable in a LASTPRIVATE clause can appear in a FIRSTPRIVATE clause.

A variable in a LASTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- `LINEAR` (*var1*:*step1* [, *var2*:*step2*]...)

var	Is a scalar variable.
step	Is a positive, integer, scalar expression.

  For each iteration of a scalar loop, *var1* is incremented by *step1*, *var2* is incremented by *step2*, and so on. Therefore, every iteration of the vector loop increments the variables by VL (vector length)*step1, VL*step2, …, to VL*stepN, respectively. If more than one step is specified for a *var*, a compile-time error occurs. Multiple LINEAR clauses are merged as a union.

  A variable in a LINEAR clause cannot appear in a REDUCTION, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.
- `PRIVATE` (*list*)

list	Is a list of names of one or more variables or common blocks that are accessible to the scoping unit. A variable that is part of another variable (for example, subobjects such as an array or structure element) cannot appear. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

  Causes each variable to be private to each iteration of a loop. Its initial and last values are undefined upon entering and exiting the SIMD loop. Multiple PRIVATE clauses are merged as a union.

  A variable in a PRIVATE clause cannot appear in a LINEAR, REDUCTION, FIRSTPRIVATE, or LASTPRIVATE clause.
- `REDUCTION` (*reduction-identifier* : *var1* [, *var2*]...)

reduction-identifier	Is a predefined reduction identifier (+, *, -, .AND., .OR., .EQV., or .NEQV.), or an accessible user-defined reduction identifier declared in a DECLARE REDUCTION directive.
var	Is a scalar variable.

  Applies the vector reduction indicated by *reduction-identifier* to *var1*, *var2*, …, *varN*. A SIMD directive can have multiple REDUCTION clauses using the same or different operators. If more than one reduction operator is associated with a *var*, a compile-time error occurs.

  A variable in a REDUCTION clause cannot appear in a LINEAR, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.
- [NO]VECREMAINDER
- `VECTORLENGTH` (*n1* [, *n2*]...)

n — Is a vector length (VL). It must be an integer that is a power of 2; the value must be 2, 4, 8, 16, 32 or 64. If you specify more than one *n*, the vectorizor will choose the VL from the values specified.

Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- VECTORLENGTHFOR (*data-type*)

data-type — Is one of the following intrinsic data types:

Data Type	Fortran Intrinsic Type
INTEGER	Default INTEGER
INTEGER(1)	INTEGER (KIND=1)
INTEGER(2)	INTEGER (KIND=2)
INTEGER(4)	INTEGER (KIND=4)
INTEGER(8)	INTEGER (KIND=8)
REAL	Default REAL
REAL(4)	REAL (KIND=4)
REAL(8)	REAL (KIND=8)
COMPLEX	Default COMPLEX
COMPLEX(4)	COMPLEX (KIND=4)
COMPLEX(8)	COMPLEX (KIND=8)

Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution where *n* is computed from `size_of_vector_register/sizeof(data_type)`.

For example, VECTORLENGTHFOR (REAL (KIND=4)) results in *n*=4 for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and *n*=8 for AVX target (packed float

operations available on 256-bit YMM registers). VECTORLENGTHFOR(INTEGER (KIND=4)) results in *n*=4 for SSE2 to AVX targets.

The VECTORLENGTHFOR and VECTORLENGTH clauses are mutually exclusive. You cannot use the VECTORLENGTHFOR clause with the VECTORLENGTH clause, and vice versa.

Multiple VECTORLENGTHFOR clauses cause a syntax error.

Without explicit VECTORLENGTH and VECTORLENGTHFOR clauses, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

If you specify the SIMD directive with no clause, default rules are in effect for variable attributes, vector length, and so forth.

If you do not explicitly specify a VECTORLENGTH clause, the compiler will choose a VECTORLENGTH using its own cost model. Misclassification of variables into PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

You can only specify a particular variable in at most one instance of a PRIVATE, LINEAR, or REDUCTION clause.

If the compiler is unable to vectorize a loop, a warning occurs by default. However, if ASSERT is specified, an error occurs instead.

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

A SIMD loop may contain one or more nested loops or be contained in a loop nest. Only the loop preceded by the SIMD directive is processed for SIMD vectorization.

The vectorization performed on this loop by the SIMD directive overrides any setting you may specify for options `-fp-model` (Linux*) and `/fp` (Windows*) for this loop.

Note that the SIMD directive may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the SIMD directive:

- The countable loop for the SIMD directive has to conform to the DO-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating-point numbers, or single- or double-precision complex numbers.
- A SIMD directive loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable the SIMD transformations for vectorization, specify option `-no-simd` (Linux*) or `/Qsimd-` (Windows*).

To disable transformations that enable more vectorization, specify options `-no-vec-no-simd` (Linux

) or `/Qvec-/Qsimd-` (Windows).

Example

Consider the following:

```
  ...
subroutine add(A, N, X)
   integer N, X
   real    A(N)
cDIR$ SIMD
   DO I=X+1, N
      A(I) = A(I) + A(I-X)
   ENDDO
end
  ...
```

When the program containing this subroutine is compiled, the DO loop will be vectorized.

Because no optional clause was specified for the directive, default rules will apply for variable attributes, vector length, and so forth.

SIN

Elemental Intrinsic Function (Generic): *Produces the sine of an argument in radians.*

Syntax

```
result = SIN (x)
```

x	(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

Results

The result type and kind are the same as *x*.

If *x* is of type real, the result is a value in radians.

If *x* is of type complex, the real part of the result is a value in radians.

Specific Name	Argument Type	Result Type
SIN	REAL(4)	REAL(4)
DSIN	REAL(8)	REAL(8)
QSIN	REAL(16)	REAL(16)
CSIN [1]	COMPLEX(4)	COMPLEX(4)
CDSIN [2]	COMPLEX(8)	COMPLEX(8)

Specific Name	Argument Type	Result Type
CQSIN	COMPLEX(16)	COMPLEX(16)

[1]The setting of compiler options specifying real size can affect CSIN.

[2]This function can also be specified as ZSIN.

Example

SIN (2.0) has the value 0.9092974.

SIN (0.8) has the value 0.7173561.

SIND

Elemental Intrinsic Function (Generic): *Produces the sine of an argument in degrees.*

Syntax

```
result = SIND (x)
```

x (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

Results

The result type and kind are the same as *x*.

Specific Name	Argument Type	Result Type
SIND	REAL(4)	REAL(4)
DSIND	REAL(8)	REAL(8)
QSIND	REAL(16)	REAL(16)

Example

SIND (2.0) has the value 3.4899496E-02.

SIND (0.8) has the value 1.3962180E-02.

SINGLE

OpenMP* Fortran Compiler Directive: *Specifies that a block of code is to be executed by only one thread in the team at a time.*

Syntax

```
!$OMP SINGLE [clause[[,] clause] ... ]
   loosely-structured-block
!$OMP END SINGLE [modifier]
-or-
!$OMP SINGLE [clause[[,] clause] ... ]
   strictly-structured-block
[!$OMP END SINGLE [modifier]]
```

clause	Is one of the following: • ALLOCATE ([allocator :] list) • COPYPRIVATE (list) • FIRSTPRIVATE (list) • NOWAIT • PRIVATE (list)
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.
modifier	Is one of the following: • COPYPRIVATE (list) • NOWAIT

The binding thread set for a SINGLE construct is the current team. A SINGLE region binds to the innermost enclosing parallel region.

Threads in the team that are not executing this directive wait at the END SINGLE directive unless NOWAIT is specified. NOWAIT can be specified as a clause in the SINGLE directive, or as a modifier in the END SINGLE directive, but not in both for a given SINGLE construct.

COPYPRIVATE can be specified as a clause in the SINGLE directive, or as a modifier in the END SINGLE directive, but not in both for a given single construct.

SINGLE directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example

In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

```
!$OMP PARALLEL DEFAULT(SHARED)
      CALL WORK(X)
!$OMP BARRIER
!$OMP SINGLE
      CALL OUTPUT(X)
      CALL INPUT(Y)
!$OMP END SINGLE
      CALL WORK(Y)
!$OMP END PARALLEL
```

You should not make assumptions as to which thread executes the SINGLE section. All other threads skip the SINGLE section and stop at the barrier at the END SINGLE construct. If other threads can proceed without waiting for the thread executing the SINGLE section, you can specify NOWAIT in the END SINGLE directive.

Parallel Processing Model for information about Binding Sets

SINH

Elemental Intrinsic Function (Generic): *Produces a hyperbolic sine.*

Syntax

```
result = SINH (x)
```

x	(Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*.

If *x* is of type complex, the imaginary part of the result is in radians.

Specific Name	Argument Type	Result Type
SINH	REAL(4)	REAL(4)
DSINH	REAL(8)	REAL(8)
QSINH	REAL(16)	REAL(16)

Example

SINH (2.0) has the value 3.626860.

SINH (0.8) has the value 0.8881060.

SIZE Function

Inquiry Intrinsic Function (Generic): *Returns the total number of elements in an array, or the extent of an array along a specified dimension.*

Syntax

```
result = SIZE (array [, dim] [, kind])
```

array	(Input) Must be an array; it can be assumed-rank. It can be of any data type. It must not be a disassociated pointer or an allocatable array that is not allocated. It can be an assumed-size array if *dim* is present with a value less than the rank of *array*.
dim	(Input; optional) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

In general, if *dim* is present, the result is the extent of dimension *dim* in *array*; otherwise, the result is the total number of elements in *array*. However, the following exceptions apply:

- If array is assumed-rank and associated with an assumed-size array and *dim* is present with a value equal to the rank of ARRAY, the result has a value of -1.
- If *dim* is absent and *array* is assumed-rank, the result has a value equal to PRODUCT(SHAPE(ARRAY, KIND)).

The setting of compiler options specifying integer size can affect this function.

Example

If B is declared as B(2:4, -3:1), then SIZE (B, DIM=2) has the value 5 and SIZE (B) has the value 15.

The following shows another example:

```
REAL(8) array (3:10, -1:3)
INTEGER i
i = SIZE(array, DIM = 2) ! returns 5
i = SIZE(array)          ! returns 40
```

See Also

SHAPE

Character Count Specifier

SIZEOF

Inquiry Intrinsic Function (Generic): *Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.*

Syntax

`result = SIZEOF (x)`

x	(Input) Can be a scalar or array. It may be of any data type. It must not be an assumed-size array. If it is an assumed-rank array, it must not be associated with an assumed-size array. If it is type CHARACTER, it cannot be a dummy argument with LEN=*.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result value is the number of bytes of storage used by *x*.

If *x* is of derived type, the result includes storage used by padding and descriptors for pointer or allocatable components, if any, but not the storage used for the data of pointer or allocatable components. If *x* is an assumed-rank array associated with an assumed-size array, the result is undefined.

Example

```
SIZEOF (3.44)              ! has the value 4

SIZEOF ('SIZE')            ! has the value 4
```

See Also

C_SIZEOF

SLEEP

Portability Subroutine: *Suspends the execution of a process for a specified interval.*

Module

USE IFPORT

Syntax

`CALL SLEEP (time)`

time	(Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.

Example

```
USE IFPORT
integer(4) hold_time
hold_time = 1    ! lets the loop execute
DO WHILE (hold_time .NE. 0)
  write(*,'(A)') "Enter the number of seconds to suspend"
  read(*,*) hold_time
  CALL SLEEP (hold_time)
END DO
END
```

See Also

SLEEPQQ

SLEEPQQ

Portability Subroutine: *Delays execution of the program for a specified duration.*

Module

USE IFPORT

Syntax

`CALL SLEEPQQ (duration)`

duration	(Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).

Example

```
USE IFPORT
INTEGER(4) delay, freq, duration
delay    = 2000
freq     = 4000
duration = 1000
CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)
END
```

SNGL

Converts a REAL value to a default REAL result.

See Also

See REAL function.

SORTQQ

Portability Subroutine: *Sorts a one-dimensional array. The array elements cannot be derived types or record structures.*

Module

USE IFPORT

Syntax

CALL SORTQQ (*adrarray*,*count*,*size*)

adrarray
(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

count
(Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. On input, number of elements in the array to be sorted. On output, number of elements actually sorted.

To be certain that SORTQQ is successful, compare the value returned in *count* to the value you provided. If they are the same, then SORTQQ sorted the correct number of elements.

size
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

Constant	Type of array
SRT$INTEGER1	INTEGER(1)
SRT$INTEGER2	INTEGER(2) or equivalent
SRT$INTEGER4	INTEGER(4) or equivalent
SRT$INTEGER8	INTEGER(8) or equivalent
SRT$REAL4	REAL(4) or equivalent
SRT$REAL8	REAL(8) or equivalent
SRT$REAL16	REAL(16) or equivalent

If the value provided in *size* is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with *size* characters per element.

Caution
The location of the array must be passed by address using the LOC function. This defeats Fortran type-checking, so you must make certain that the *count* and *size* arguments are correct.

If you pass invalid arguments, SORTQQ attempts to sort random parts of memory. If the memory it attempts to sort is allocated to the current process, that memory is sorted; otherwise, the operating system intervenes, the program is halted, and you get a General Protection Violation message.

Example

```
!    Sort a 1-D array
USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i
DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 2223, 67/
!    Sort the array
```

```
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)
!    Display the sorted array
DO i = 1, 10
  WRITE (*, 9000) i, array (i)
9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END
```

LOC

SPACING

Elemental Intrinsic Function (Generic): *Returns the absolute spacing of model numbers near the argument value.*

Syntax

`result = SPACING (x)`

x (Input) Must be of type real.

Results

The result type and kind are the same as *x*. The result has the value b $^{e-p}$. Parameters *b*, *e*, and *p* are defined in Model for Real Data. If the result value is outside of the real model range, the result is TINY(*x*).

Example

If 3.0 is a REAL(4) value, SPACING (3.0) has the value 2 $^{-22}$.

The following shows another example:

```
REAL(4) res4
REAL(8) res8, r2
res4 = SPACING(3.0)   ! returns 2.384186E-07
res4 = SPACING(-3.0)  ! returns 2.384186E-07
r2   = 487923.3
res8 = SPACING(r2)    ! returns 5.820766091346741E-011
```

SPLITPATHQQ

Portability Function: *Breaks a file path or directory path into its components.*

Module

USE IFPORT

Syntax

`result = SPLITPATHQQ (path,drive,dir,name,ext)`

path	(Input) Character*(*). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in *path*.
drive	(Output) Character*(*). Drive letter followed by a colon.
dir	(Output) Character*(*). Path of directories, including the trailing slash.
name	(Output) Character*(*). Name of file or, if no file is specified in *path*, name of the lowest directory. A file name must not include an extension.
ext	(Output) Character*(*). File name extension, if any, including the leading period (.).

Results

The result type is INTEGER(4). The result is the length of *dir*.

The *path* parameter can be a complete or partial file specification.

$MAXPATH is a symbolic constant defined in module IFPORT.F90 as 260.

Example

```
USE IFPORT
CHARACTER($MAXPATH) buf
CHARACTER(3)        drive
CHARACTER(256)      dir
CHARACTER(256)      name
CHARACTER(256)      ext
CHARACTER(256)      file

INTEGER(4)          length

buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext

END
```

FULLPATHQQ

SPREAD

Transformational Intrinsic Function (Generic):
Creates a replicated array with an added dimension by making copies of existing elements along a specified dimension.

Syntax

```
result = SPREAD (source,dim,ncopies)
```

source	(Input) Must be a scalar or array. It may be of any data type. The rank must be less than 31.

dim	(Input) Must be scalar and of type integer. It must have a value in the range 1 to n + 1 (inclusive), where *n* is the rank of *source*.
ncopies	Must be scalar and of type integer. It becomes the extent of the additional dimension in the result.

Results

The result is an array of the same type as *source* and of rank that is one greater than *source*.

If *source* is an array, each array element in dimension *dim* of the result is equal to the corresponding array element in *source*.

If *source* is a scalar, the result is a rank-one array with *ncopies* elements, each with the value *source*.

If *ncopies* less than or equal to zero, the result is an array of size zero.

Example

SPREAD ("B", 1, 4) is the character array (/"B", "B", "B", "B"/).

B is the array [3, 4, 5] and NC has the value 4.

SPREAD (B, DIM=1, NCOPIES=NC) produces the array

```
 [ 3  4  5 ]
 [ 3  4  5 ]
 [ 3  4  5 ]
 [ 3  4  5 ].
```

SPREAD (B, DIM=2, NCOPIES=NC) produces the array

```
 [3  3  3  3 ]
 [4  4  4  4 ]
 [5  5  5  5 ].
```

The following shows another example:

```
INTEGER AR1(2, 3), AR2(3, 2)
AR1 = SPREAD((/1,2,3/),DIM= 1,NCOPIES= 2) ! returns
                                          ! 1 2 3
                                          ! 1 2 3

AR2 = SPREAD((/1,2,3/), 2, 2)   ! returns   1 1
                                !           2 2
                                !           3 3
```

RESHAPE

SQRT

Elemental Intrinsic Function (Generic): *Produces the square root of its argument.*

Syntax

`result = SQRT (x)`

x	(Input) must be of type real or complex. If *x* is type real, its value must be greater than or equal to zero.

Results

The result type and kind are the same as *x*. The result has a value equal to the square root of *x*.

A result of type complex is the principal value, with the real part greater than or equal to zero.

When the real part of the result is zero, the imaginary part of the result has the same sign as the imaginary part of *x* , even if the imaginary part of *x* is a negative real zero.

Specific Name	Argument Type	Result Type
SQRT	REAL(4)	REAL(4)
DSQRT	REAL(8)	REAL(8)
QSQRT	REAL(16)	REAL(16)
CSQRT [1]	COMPLEX(4)	COMPLEX(4)
CDSQRT[2]	COMPLEX(8)	COMPLEX(8)
CQSQRT	COMPLEX(16)	COMPLEX(16)

[1]The setting of compiler options specifying real size can affect CSQRT.

[2]This function can also be specified as ZSQRT.

Example

SQRT (16.0) has the value 4.0.

SQRT (3.0) has the value 1.732051.

The following shows another example:

```
! Calculate the hypotenuse of a right triangle
! from the lengths of the other two sides.
REAL sidea, sideb, hyp
sidea = 3.0
sideb = 4.0
hyp = SQRT (sidea**2 + sideb**2)
WRITE (*, 100) hyp
100 FORMAT (/ ' The hypotenuse is ', F10.3)
END
```

SRAND

Portability Subroutine: *Seeds the random number generator used with IRAND and RAND.*

Module

USE IFPORT

Syntax

`CALL SRAND (iseed)`

iseed (Input) INTEGER(4). Any value. The default value is 1.

SRAND seeds the random number generator used with IRAND and RAND. Calling SRAND is equivalent to calling IRAND or RAND with a new seed.

The same value for *iseed* generates the same sequence of random numbers. To vary the sequence, call SRAND with a different *iseed* value each time the program is executed.

Example

```
!  How many random numbers out of 100 will be between .5 and .6?
   USE IFPORT
   ICOUNT = 0
   CALL SRAND(123)
   DO I = 1, 100
     X = RAND(0)
     IF ((X>.5).AND.(x<.6)) ICOUNT = ICOUNT + 1
   END DO
   WRITE(*,*) ICOUNT, "numbers between .5 and .6!"
   END
```

SSWRQQ

Portability Subroutine: *Returns the floating-point processor status word.*

Module

USE IFPORT

Syntax

`CALL SSWRQQ (status)`

status (Output) INTEGER(2). Floating-point processor status word.

SSWRQQ performs the same function as the runtime subroutine GETSTATUSFPQQ and is provided for compatibility.

Example

```
USE IFPORT
INTEGER(2) status
CALL SSWRQQ (status)
```

See Also

LCWRQQ
GETSTATUSFPQQ

STAT

Portability Function: *Returns detailed information about a file.*

Module

USE IFPORT

Syntax

`result = STAT (name,statb)`

name

(Input) Character*(*). Name of the file to examine.

statb

(Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of *statb* contain the following values:

Element	Description	Values or Notes
statb(1)	Device the file resides on	Windows: Always 0 Linux: System dependent
statb(2)	File inode number	Windows: Always 0 Linux: System dependent
statb(3)	Access mode of the file	See the table in Results
statb(4)	Number of hard links to the file	Windows: Always 1 Linux: System dependent
statb(5)	User ID of owner	Windows: Always 1 Linux: System dependent
statb(6)	Group ID of owner	Windows: Always 1 Linux: System dependent
statb(7)	Raw device the file resides on	Windows: Always 0 Linux: System dependent
statb(8)	Size of the file	
statb(9)	Time when the file was last accessed[1]	Windows: Only available on non-FAT file systems; undefined on FAT systems Linux: System dependent
statb(10)	Time when the file was last modified[1]	
statb(11)	Time of last file status change[1]	Windows: Same as stat(10) Linux: System dependent

Element	Description	Values or Notes
statb(12)	Blocksize for file system I/O operations	Windows: Always 1 Linux: System dependent

[1]Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

Results

The result type is INTEGER(4).

On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code ENOENT (the specified file could not be found). On Linux* systems, the file inquired about must be currently connected to a logical unit and must already exist when STAT is called; if STAT fails, `errno`is set.

For a list of other error codes, see IERRNO.

The access mode (the third element of *statb*) is a bitmap consisting of an IOR of the following constants:

Symbolic name	Constant	Description	Notes
S_IFMT	O'0170000'	Type of file	
S_IFDIR	O'0040000'	Directory	
S_IFCHR	O'0020000'	Character special	Never set on Windows systems
S_IFBLK	O'0060000'	Block special	Never set on Windows systems
S_IFREG	O'0100000'	Regular	
S_IFLNK	O'0120000'	Symbolic link	Never set on Windows systems
S_IFSOCK	O'0140000'	Socket	Never set on Windows systems
S_ISUID	O'0004000'	Set user ID on execution	Never set on Windows systems
S_ISGID	O'0002000'	Set group ID on execution	Never set on Windows systems
S_ISVTX	O'0001000'	Save swapped text	Never set on Windows systems
S_IRWXU	O'0000700'	Owner's file permissions	
S_IRUSR, S_IREAD	O'0000400'	Owner's read permission	Always true on Windows systems
S_IWUSR, S_IWRITE	O'0000200'	Owner's write permission	

Symbolic name	Constant	Description	Notes
S_IXUSR, S_IEXEC	O'0000100'	Owner's execute permission	Based on file extension (.EXE, .COM, .CMD, or .BAT)
S_IRWXG	O'0000070'	Group's file permissions	Same as S_IRWXU on Windows systems
S_IRGRP	O'0000040'	Group's read permission	Same as S_IRUSR on Windows systems
S_IWGRP	O'0000020'	Group's write permission	Same as S_IWUSR on Windows systems
S_IXGRP	O'0000010'	Group's execute permission	Same as S_IXUSR on Windows systems
S_IRWXO	O'0000007'	Other's file permissions	Same as S_IRWXU on Windows systems
S_IROTH	O'0000004'	Other's read permission	Same as S_IRUSR on Windows systems
S_IWOTH	O'0000002'	Other's write permission	Same as S_IWUSR on Windows systems
S_IXOTH	O'0000001'	Other's execute permission	Same as S_IXUSR on Windows systems

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows* systems, LSTAT returns exactly the same information as STAT. On Linux systems, if the file denoted by *name* is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

You can also use the INQUIRE statement to get information about file properties.

Example

```
USE IFPORT
CHARACTER*12 file_name
INTEGER(4) info_array(12)
print *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
  print *, info_array else
  print *, 'Error = ',istatus
end if
end
```

FSTAT

Statement Function

Statement: *Defines a function in a single statement in the same program unit in which the procedure is referenced. Statement functions are an obsolescent feature of the Fortran standard. We recommend that you use internal procedures.*

Syntax

fun([*d-arg* [,*d-arg*]...]) = *expr*

fun	Is the name of the statement function. It must be declared, either implicitly or explicitly, to be scalar. Its type must not be a parameterized derived type.
d-arg	Is a dummy argument. A dummy argument can appear only once in any list of dummy arguments, and its scope is local to the statement function. It must be declared, either implicitly or explicitly, to be scalar.
expr	Is a scalar expression defining the computation to be performed. Named constants and variables used in the expression must have been declared previously in the specification part of the scoping unit or made accessible by use or host association. If the expression contains a function or statement function reference, that function must have been declared previously as a function, or defined previously as a statement function in the same program unit. A statement function reference takes the following form: *fun* ([*a-arg*[, *a-arg*] ...])
a-arg	Is an actual argument.

Description

When a statement function reference appears in an expression, the values of the actual arguments are associated with the dummy arguments in the statement function definition. The expression in the definition is then evaluated. The resulting value is used to complete the evaluation of the expression containing the function reference.

The data type of a statement function can be explicitly defined in a type declaration statement. If no type is specified, the type is determined by implicit typing rules in effect for the program unit.

Actual arguments must agree in number, order, and data type with their corresponding dummy arguments.

Except for the data type, declarative information associated with an entity is not associated with dummy arguments in the statement function; for example, declaring an entity to be an array or to be in a common block does not affect a dummy argument with the same name.

The name of the statement function cannot be the same as the name of any other entity within the same program unit.

Any reference to a statement function must appear in the same program unit as the definition of that function.

A statement function reference must appear as (or be part of) an expression. The reference cannot appear on the left side of an assignment statement.

A statement function must not be provided as a procedure argument.

A statement function is PURE if the only functions it references are PURE and it does not reference a data object with the VOLATILE attribute.

Example

The following are examples of statement functions:

```
REAL VOLUME, RADIUS
VOLUME(RADIUS) = 4.189*RADIUS**3

CHARACTER*10 CSF,A,B
CSF(A,B) = A(6:10)//B(1:5)
```

The following example shows a statement function and some references to it:

```
AVG(A,B,C) = (A+B+C)/3.
...
GRADE = AVG(TEST1,TEST2,XLAB)
IF (AVG(P,D,Q) .LT. AVG(X,Y,Z)) STOP
FINAL = AVG(TEST3,TEST4,LAB2)       ! Invalid reference; implicit
...                                 ! type of third argument does not
...                                 ! match implicit type of dummy argument
```

Implicit typing problems can be avoided if all arguments are explicitly typed.

The following statement function definition is invalid because it contains a constant, which cannot be used as a dummy argument:

```
REAL COMP, C, D, E
COMP(C,D,E,3.) = (C + D - E)/3.
```

The following shows another example:

```
Add (a, b) = a + b
REAL(4) y, x(6)
. . .
DO n = 2, 6
  x(n) = Add (y, x(n-1))
END DO
```

Use and Host Association

STATIC

Statement and Attribute: *Controls the storage allocation of variables in subprograms (as does AUTOMATIC). Variables declared as STATIC and allocated in memory reside in the static storage area, rather than in the stack storage area.*

Syntax

The STATIC attribute can be specified in a type declaration statement or a STATIC statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] STATIC [, *att-ls*] :: *v*[, *v*] ...

Statement:

```
STATIC[::] v[, v] ...
```

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
v	Is the name of a variable or an array specification. It can be of any type.

STATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

By default, the compiler allocates local scalar variables of non-recursive subprograms in the static storage area. Local arrays, except for allocatable arrays, are in the static storage area by default.

The compiler may choose to allocate a variable in temporary (stack or register) storage if it notices that the variable is always defined before use. Appropriate use of the SAVE attribute can prevent compiler warnings if a variable is used before it is defined.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

To override any compiler option that may affect variables, explicitly specify the variables as STATIC.

> **NOTE**
> Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as STATIC more than once in the same scoping unit.

If the variable is a pointer, STATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as STATIC. The following table shows these restrictions:

Variable	STATIC
Dummy argument	No
Automatic object	No
Common block item	Yes
Use-associated item	No
Function result	No
Component of a derived type	No

A variable can be specified with both the STATIC and SAVE attributes.

If a variable is in a module's outer scope, it can be specified as STATIC.

Example

The following example shows a type declaration statement specifying the STATIC attribute:

```
INTEGER, STATIC :: ARRAY_A
```

The following example shows a STATIC statement:

```
...
CONTAINS
 INTEGER FUNCTION REDO_FUNC
   INTEGER I, J(10), K
   REAL C, D, E(30)
   AUTOMATIC I, J, K(20)
   STATIC C, D, E
   ...
 END FUNCTION
...
 INTEGER N1, N2
 N1 = -1
 DO WHILE (N1)
   N2 = N1*2
   call sub1(N1, N2)
   read *, N1
 END DO
 CONTAINS
 SUBROUTINE sub1 (iold, inew)
 INTEGER, intent(INOUT):: iold
 integer, STATIC ::N3
 integer, intent(IN) :: inew
 if (iold .eq. -1) then
   N3 = iold
 end if
 print *, 'New: ', inew, 'N3: ',N3
 END subroutine
 !
 END
```

STOP and ERROR STOP

Statements: *The STOP statement initiates normal termination of an image before the execution of an END statement of the main program. The ERROR STOP statement initiates error termination.*

Syntax

STOP [*stop-code*] [, QUIET = *scalar-logical-expr*]

ERROR STOP [*stop-code*] [, QUIET = *scalar-logical-expr*]

stop-code (Optional) A message. It can be any of the following:

- A scalar character expression of type default character
- A scalar default integer expression

An ERROR STOP statement can appear in a PURE procedure, a STOP statement cannot appear.

If QUIET= is not specified, or if *scalar-logical-expr* is false, the STOP or ERROR STOP statement does the following:

- If *stop-code* is specified, writes the specified message to the standard error device.
- Writes one or more of the following messages to the standard error device indicating which IEEE floating-point exceptions are signaling if `assume fpe-summary` is specified:

```
IEEE_DIVIDE_BY_ZERO is signaling
IEEE_INVALID is signaling
IEEE_OVERFLOW is signaling
IEEE_UNDERFLOW is signaling
```

- STOP initiates normal termination on the image that executes it. ERROR STOP initiates error termination. If *stop-code* is a character expression, STOP returns a status of zero and ERROR STOP returns a status of non-zero. If *stop-code* is an integer, a status equal to *stop-code* is returned for both STOP and ERROR_STOP.

If *stop-code* is not specified, or if QUIET= is specified and *scalar-logical-expr* has the value .TRUE., the executing image initiates normal or error termination, and no message is printed; for STOP, a status of zero is returned; for ERROR STOP, a positive status value of 128 is returned

When a program is running on multiple images, a STOP statement on one image does not affect the other images; they can continue to reference and define the coarrays located on the stopped image. An ERROR STOP initiates execution termination on all images, which may include flushing of I/O buffers, closing of I/O files, and reporting error status on one or more images.

Effect on Windows* Systems

In QuickWin programs, the following is displayed in a message box:

```
Program terminated with Exit Code stop-code
```

If the application has no console window, the stop-code is displayed in a message box.

Effect on Linux* Systems

Operating system shells (such as bash, sh, csh, dash, etc.) work with a one byte exit status. So, when *stop-code* is an integer, only the lowest byte is significant. For example, consider the following statement:

```
STOP 99999
```

In this case, the program returns a status equal to 159 because integer 99999 = Z'1869F', and the lowest byte is equal to Z'9F', which equals 159.

Example

The following examples show valid STOP statements:

```
STOP 98
STOP 'END OF RUN', QUIET=(J.EQ.K)

DO
```

```
  READ *, X, Y
  IF (X > Y) STOP 5555
END DO
```

The following shows another example:

```
      OPEN(1,FILE='file1.dat', status='OLD', ERR=100)
      . . .
 100  STOP 'ERROR DETECTED!'
      END
```

`assume` compiler option
EXIT
Program Termination

STOPPED_IMAGES

Transformational Intrinsic Function (Generic): *Returns an array of index images that have initiated normal termination.*

Syntax

`result = STOPPED_IMAGES ([team, kind])`

team	(Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.
kind	(Input; optional) Must be a scalar integer expression with a value that is a valid INTEGER kind type parameter.

Results

The result is a rank-one integer array with the same type kind parameters as *kind* if present; otherwise, default integer. The size of the array is equal to the number of images in the specified team that have initiated normal termination.

The result array elements are the image index values of images on the specified team that have initiated normal termination. The indices are arranged in increasing numeric order.

Example

If image 5 and 12 of the current team have initiated normal termination, the result of STOPPED_IMAGES ( ) is an array of default integer type with size 2 defined with the value [5, 12]. If no images in the current team are known to have failed, the result of STOPPED_IMAGES ( ) is a zero-sized array.

See Also

FAILED_IMAGES
IMAGE_STATUS

STORAGE_SIZE

Inquiry Intrinsic Function (Generic): *Returns the storage size in bits.*

Syntax

`result = STORAGE_SIZE (a [, kind])`

a	(Input) Must be a scalar or array. It can be of any type. If it has any deferred type parameters it must not be an unallocated allocatable variable, or a disassociated, or undefined pointer.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is the size expressed in bits for an element of an array that has the dynamic type and kind parameters of *a*.

If the type and kind parameters are such that storage association applies, the result is consistent with the named constants defined in the intrinsic module ISO_FORTRAN_ENV.

An array element may take more bits to store than a scalar, since any hardware-imposed alignment requirements for array elements may not apply to a scalar variable.

NOTE
The result is intended to be the size in memory that an object takes when it is stored. This size may differ from the size it takes during expression handling (which may be the native register size) or when stored in a file. If an object is never stored in memory but only in a register, this function returns the size it would take if it were stored in memory.

Example

STORAGE_SIZE (1.0) has the same value as the named constant NUMERIC_STORAGE_SIZE in the intrinsic module ISO_FORTRAN_ENV.

See Also

Storage Association
ISO_FORTRAN_ENV Module

STRICT and NOSTRICT

General Compiler Directive: *STRICT disables language features not found in the language standard specified on the command line (Fortran 2018, Fortran 2008, Fortran 2003, Fortran 95, or Fortran 90). NOSTRICT (the default) enables these features.*

Syntax

```
!DIR$ STRICT
```

```
!DIR$ NOSTRICT
```

If STRICT is specified and no language standard is specified on the command line, the default is to disable features not found in Fortran 2018.

The STRICT and NOSTRICT directives can appear only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. STRICT and NOSTRICT cannot appear between program units, or at the beginning of internal subprograms. They do not affect any modules invoked with the USE statement in the program unit that contains them.

Example

```
! NOSTRICT by default
TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff
TYPE (stuff) examp
DOUBLE COMPLEX cd  ! non-standard data type, no error
cd =(3.0D0, 4.0D0)
examp.k = 4        ! non-standard component designation,
                   ! no error
END
SUBROUTINE STRICTDEMO( )
  !DIR$ STRICT
   TYPE stuff
    INTEGER(4) k
    INTEGER(4) m
    CHARACTER(4) name
   END TYPE stuff
   TYPE (stuff) samp
   DOUBLE COMPLEX cd   ! ERROR
   cd =(3.0D0, 4.0D0)
   samp.k = 4          ! ERROR
END SUBROUTINE
```

STRUCTURE and END STRUCTURE

Statement: *Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.*

Syntax

```
STRUCTURE [/structure-name/] [field-namelist]
   field-declaration
   [field-declaration]
   . . .
   [field-declaration]
END STRUCTURE
```

structure-name

Is the name used to identify a structure, enclosed by slashes.

Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks.

Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

field-namelist

Is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.

field-declaration

Also called the declaration body. A *field-declaration* consists of any combination of the following:

- Type declarations

  These are ordinary Fortran data type declarations.
- Substructure declarations

  A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.
- Union declarations

  A union declaration is composed of one or more mapped field declarations.
- PARAMETER statements

  PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

  Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

```
  INTEGER*4 P
STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
END STRUCTURE
  REAL*4 A(P)
```

The Standard Fortran derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.

In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.

A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).

Example

An item can be a RECORD statement that references a previously defined structure type:

```
STRUCTURE /full_address/
  RECORD  /full_name/ personsname
  RECORD  /address/   ship_to
  INTEGER*1           age
  INTEGER*4           phone
END STRUCTURE
```

You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address`structure defined in the previous example:

```
RECORD /full_address/ shippingaddress
```

In this case, the `age`item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.

In the following example, the declaration defines a structure named `APPOINTMENT`. `APPOINTMENT` contains the structure `DATE`(field `APP_DATE`) as a substructure. It also contains a substructure named `TIME`(field `APP_TIME`, an array), a CHARACTER*20 array named `APP_MEMO`, and a LOGICAL*1 field named `APP_FLAG`.

```
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/
  RECORD /DATE/     APP_DATE
  STRUCTURE /TIME/  APP_TIME (2)
    INTEGER*1       HOUR, MINUTE
  END STRUCTURE
  CHARACTER*20      APP_MEMO (4)
  LOGICAL*1         APP_FLAG
END STRUCTURE
```

The length of any instance of structure `APPOINTMENT` is 89 bytes.

The following figure shows the memory mapping of any record or record array element with the structure APPOINTMENT.

Memory Map of Structure APPOINTMENT

SUBDEVICE

Parallel Directive Clause: *Specifies which tiles or compute slices (c-slices) of the offload device the offloaded code will run on. This feature is only available for ifx.*

Syntax

```
SUBDEVICE ( [level,] start [:length [:stride]] )
```

level	Is a non-negative integer constant. If *level* is not specified, the value 0 is used.
start	Is a non-negative integer expression.
length	Is a positive integer expression. If *length* is not specified, the value 1 is used.
stride	Is a positive integer expression. If *stride* is not specified, the value 1 is used.

The SUBDEVICE clause specifies which sub-devices the offloaded code is to execute on. A GPU device may be made up of multiple tiles, and each tile may be made up of multiple compute slices (also called c-slices).

Specifying level 0 selects tiles, specifying level 1 selects c-slices. The tiles and c-slices are numbered 0 to *n*. start, length, and stride act like an array section subscript to select the indices of the tiles or c-slices the offloaded code will execute on.

At most one SUBDEVICE clause can appear in a directive that allows the clause.

Example

subdevice (0, 2:5) runs on tiles 2, 3, 4, and 5.

subdevice (1, 2:6:2) runs on compute slices 2, 4 and 6.

SUBMODULE

Statement: *Marks the beginning of a submodule program unit, which contains specifications and definitions that can be used by one or more program units.*

Syntax

```
SUBMODULE (ancestor-module-name [:parent-submodule-name]) name
   [specification-part]
   [module-subprogram
   [module-subprogram]...]
END [SUBMODULE [name]]
```

ancestor-module-name	Must be the name of a nonintrinsic module. It is the name of the module at the root of the module or submodule tree.
parent-submodule-name	(Optional) Is the name of the parent submodule, if any. The parent submodule must be a descendant of *ancestor-module-name*.
name	Is the name of the submodule.
specification-part	Is one or more specification statements, except for the following: • ENTRY • FORMAT • AUTOMATIC (or its equivalent attribute) • INTENT (or its equivalent attribute)

	• OPTIONAL (or its equivalent attribute) • Statement functions An automatic object must not appear in a specification statement.
module-subprogram	Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE. A module subprogram can contain internal procedures.

Description

If a name follows the END statement, it must be the same as the name specified in the SUBMODULE statement.

Each submodule has exactly one ancestor module and exactly one parent module or submodule. If the parent is a module then it must be the ancestor module. The relationship is tree-like, with the parent module or submodule at the root of the tree, and its descendant submodules as the branches of the tree.

A module or submodule may have one or more descendent submodules.

A submodule can access the entities from its parent module or submodule by host association. Unlike a module, a submodule cannot be referenced in other program units by use association. Entities declared in a submodule are only accessible from the submodule and its descendent submodules. Furthermore, a module procedure can have its interface declared in a module or submodule and its implementation contained in a descendent submodule in a separate file.

Submodules help the modularization of a large module in several ways:

- Internal data can be shared among submodules without being exposed to users of the module. Without the submodule feature, when a large module is split into smaller modules, internal data may be forced to become public in order to be shared among the modules.
- Even if a module procedure implementation in a submodule is changed, as long as the module procedure interface declared in the ancestor module remains the same, a recompilation would not be needed for the user of the module. This could reduce the rebuilding time for a complex system.
- Separate concepts with circular dependencies can now be implemented in different submodules. It cannot be done with just modules.

A submodule is uniquely identified by a *submodule identifier* which consists of its *ancestor-module-name* and the name of the submodule. The name of a submodule can therefore be the same as the name of another submodule so long as they do not have the same ancestor module.

The following rules also apply to submodules:

- The specification part of a submodule must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
- A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the *specification-part* of a submodule includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Unlike a module, the specification part of a submodule must not contain PUBLIC and PRIVATE specifications.

Any executable statements in a module or submodule can only be specified in a module or submodule subprogram.

A submodule can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

Example

Consider the following example of a multilevel submodule system:

		Module M		
	Submodule A		Submodule B	Submodule C
Submodule X	Submodule Y	Submodule Z		

In the above example, module M is extended by submodules up to two levels. Module M is the ancestor module of all the submodules. Entities declared in module M can be shared among all the submodules. A is the parent submodule of X, Y, and Z. Entities declared in submodule A can be shared among submodules X, Y, and Z, but not by B or C.

Only public entities declared in M can be available to other program units by use association.

The SUBMODULE declarations for A and X are:

```
SUBMODULE (M) A
   …
END SUBMODULE A

SUBMODULE (M : A) X
   …
END SUBMODULE X
```

The following example shows modules and submodules, separate module procedures, and how circular dependency can be avoided with submodules. There are five parts in the example:

1. module color_points
2. level-1 submodule color_points_a
3. level-2 submodule color_points_b
4. module palette_stuff
5. program main

```
! part 1
module color_points  ! This is the ancestor module
   type color_point
      private
      real :: x, y
      integer :: color
   end type color_point

   ! Below is the interface declaration of the separate module procedures.
   ! No IMPORT statement is used in the interface bodies.
   ! The separate module procedures are implemented in the two submodules.
   interface
      module subroutine color_point_del ( p )
      type(color_point), allocatable :: p
      end subroutine color_point_del

      real module function color_point_dist ( a, b )
      type(color_point), intent(in) :: a, b
      end function color_point_dist

      module subroutine color_point_draw ( p )
      type(color_point), intent(in) :: p
      end subroutine color_point_draw
```

```
      module subroutine color_point_new ( p )
      type(color_point), allocatable :: p
      end subroutine color_point_new
   end interface
end module color_points

! part 2
submodule ( color_points ) color_points_a  ! submodule of color_points
   integer :: instance_count = 0

   ! Below is the interface declaration of the separate module procedure
   !   inquire_palette, which is implemented in the submodule color_points_b.
   interface
      module subroutine inquire_palette ( pt, pal )
         use palette_stuff
         ! Later you will see that module palette_stuff uses color_points.
         ! This use of palette_stuff however does not cause a circular
         !   dependence because this use is not in the module.
         type(color_point), intent(in) :: pt
         type(palette), intent(out) :: pal
      end subroutine inquire_palette
   end interface

contains
   ! Here are the implementations of three of the four separate module
   !   procedures declared in module color_point.
   module subroutine color_point_del ( p )
     type(color_point), allocatable :: p
     instance_count = instance_count - 1
     deallocate ( p )
   end subroutine color_point_del

   real module function color_point_dist ( a, b ) result ( dist )
     type(color_point), intent(in) :: a, b
     dist = sqrt( (b%x - a%x)**2 + (b%y - a%y)**2 )
   end function color_point_dist

   module subroutine color_point_new ( p )
     type(color_point), allocatable :: p
     instance_count = instance_count + 1
     allocate ( p )
   end subroutine color_point_new

end submodule color_points_a

! part 3
submodule ( color_points:color_points_a ) color_points_b
! submodule of color_point_a
contains
   ! Implementation of a module procedure declared in the ancestor module
   module subroutine color_point_draw ( p )
     use palette_stuff, only: palette
     type(color_point), intent(in) :: p
     type(palette) :: MyPalette
     ...; call inquire_palette ( p, MyPalette ); ...
```

```
   end subroutine color_point_draw

   ! Implementation of a module procedure declared in the parent submodule
   module procedure inquire_palette
     ...
   end procedure inquire_palette

   ! A procedure only accessible from color_points_b and its submodules
   subroutine private_stuff
     ...
   end subroutine private_stuff

end submodule color_points_b

! part 4
module palette_stuff
   type :: palette ; ... ; end type palette
contains
   subroutine test_palette ( p )
     use color_points
     ! This does not cause a circular dependency because the
     !  "use palette_stuff" that is logically within color_points
     !  is in the color_points_a submodule.
     type(palette), intent(in) :: p
     ...
   end subroutine test_palette
end module palette_stuff

! part 5
program main
   use color_points
   ! Only public entities in color_points can be accessed here, not the
   !   entities from its submodules.

   ! The separate module procedure color_point_draw can be a specific
   !   procedure for a generic here. Recall that color_point_draw is
   !   implemented in a submodule, but its interface is public in a module.
   interface draw
     module procedure color_point_draw
   end interface

   type(color_point), allocatable :: c_1, c_2
   real :: rc
   ...
   call color_point_new (c_1)  ! body in color_points_a, interface in
                               !   color_points
   ...
   call draw (c_1)             ! body in color_points_b, specific interface
                               !   in color_points, generic interface here
   ...
   rc = color_point_dist (c_1, c_2)  ! body in color_points_a, interface in
                                     !   color_points
   ...
   call color_point_del (c_1)  ! body in color_points_a, interface in
```

```
                                !   color_points
   ...
end program main
```

MODULE
FUNCTION
SUBROUTINE
References to Generic Procedures

SUBROUTINE

Statement: *The initial statement of a subroutine subprogram. A subroutine subprogram is invoked in a CALL statement or by a defined assignment or operator, and does not return a particular value.*

Syntax

```
[prefix [prefix]] SUBROUTINE name [([d-arg-list]) [lang-binding]]
   [specification-part]
   [execution-part]
[CONTAINS
   [internal-subprogram-part] ]
END [SUBROUTINE [name]]
```

prefix

(Optional) Is any of the following:

- ELEMENTAL

  Acts on one array element at a time. This is a restricted form of a procedure.
- IMPURE

  Asserts that the procedure has side effects.
- MODULE

  Indicates a separate module procedure. See separate module procedures.
- NON_RECURSIVE

  Indicates a procedure is not recursive.
- PURE

  Asserts that the procedure has no side effects.
- RECURSIVE

  Permits direct or indirect recursion to occur.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if *lang-binding* is specified.

name

Is the name of the subroutine.

d-arg-list

(Optional) Is a list of one or more dummy arguments or alternate return specifiers (*) .

lang-binding	(Optional) Takes the following form: `BIND (C [, NAME=`*ext-name*`])` *ext-name* — Is a character scalar constant expression that can be used to construct the external name.
specification-part	Is one or more specification statements.
execution-part	Is one or more executable constructs or statements.
internal-subprogram-part	Is one or more internal subprograms (defining internal procedures). The *internal-subprogram-part* is preceded by a CONTAINS statement.

Description

A subroutine is invoked by a CALL statement or defined assignment. When a subroutine is invoked, dummy arguments (if present) become associated with the corresponding actual arguments specified in the call.

Execution begins with the first executable construct or statement following the SUBROUTINE statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

A subroutine subprogram *cannot* contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A subroutine can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

You need an interface block for a subroutine when:

- Calling arguments use argument keywords.
- Some arguments are optional.
- A dummy argument is an assumed-shape array, allocatable, a coarray, a pointer, or a target.
- The subroutine extends intrinsic assignment.
- The subroutine can be referenced by a generic name.
- The subroutine is in a dynamic-link library.

If the subroutine is in a DLL and is called from your program, use the option DLLEXPORT or DLLIMPORT, which you can specify with the ATTRIBUTES directive.

Note that if you specify *lang-binding*, you have to use the parentheses even if there are no arguments. For example, without *lang-binding* you can specify `SUBROUTINE F` but with *lang-binding* you have to specify `SUBROUTINE F( ) BIND (C)`.

Example

The following example shows a subroutine:

```
Main ProgramSubroutine
CALL HELLO_WORLD      SUBROUTINE HELLO_WORLD
...                   PRINT *, "Hello World"
END                   END SUBROUTINE
```

The following example uses alternate return specifiers to determine where control transfers on completion of the subroutine:

```
Main ProgramSubroutine
    CALL CHECK(A,B,*10,*20,C)             SUBROUTINE CHECK(X,Y,*,*,Q)
    TYPE *, 'VALUE LESS THAN ZERO'        ...
    GO TO 30                        50    IF (Z)  60,70,80
10  TYPE*, 'VALUE EQUALS ZERO'      60    RETURN
```

```
    GO TO 30                          70  RETURN 1
20  TYPE*, 'VALUE MORE THAN ZERO'     80  RETURN 2
30  CONTINUE                              END
    ...
```

The SUBROUTINE statement argument list contains two dummy alternate return arguments corresponding to the actual arguments *10 and *20 in the CALL statement argument list.

The value of Z determines the return, as follows:

- If Z < zero, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the main program.
- If Z = = zero, the return is to statement label 10 in the main program.
- If Z > zero, the return is to statement label 20 in the main program.

Note that an alternate return is an obsolescent feature in the Fortran Standard.

The following shows another example:

```
    SUBROUTINE GetNum (num, unit)
    INTEGER num, unit
10  READ (unit, '(I10)', ERR = 10) num
    END
   ...
```

SUM

Transformational Intrinsic Function (Generic):
Returns the sum of all the elements in an entire array or in a specified dimension of an array.

Syntax

`result = SUM (array [, mask])`

`result = SUM (array, dim [, mask])`

array	(Input) Must be an array of type integer, real, or complex.
dim	(Input) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*.

mask (Input; optional) Must be of type logical and conformable with *array*.

Results

The result is an array or a scalar of the same data type as *array*.

The result is a scalar if *dim* is not specified or *array* has rank one.

The following rules apply if *dim* is not specified:

- If SUM(*array*) is specified, the result is the sum of all elements of *array*. If *array* has size zero, the result is zero.
- If SUM(*array*, MASK= *mask*) is specified, the result is the sum of all elements of *array* corresponding to true elements of *mask*. If *array* has size zero, or every element of *mask* has the value .FALSE., the result is zero.

The following rules apply if *dim* is specified:

- If *array* has rank one, the value is the same as SUM(*array*[,MASK= *mask*]).
- An array result has a rank that is one less than *array*, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of *array*.
- The value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n) of SUM(*array*, *dim*[, *mask*]) is equal to SUM(*array*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) [,MASK = *mask*(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)].

Example

SUM ((/2, 3, 4/)) returns the value 9 (sum of 2 + 3 + 4). SUM ((/2, 3, 4/), DIM=1) returns the same result.

SUM (B, MASK=B .LT. 0.0) returns the arithmetic sum of the negative elements of B.

C is the array

```
 [ 1  2  3 ]
 [ 4  5  6 ].
```

SUM (C, DIM=1) returns the value (5, 7, 9), which is the sum of all elements in each column. 5 is the sum of 1 + 4 in column 1. 7 is the sum of 2 + 5 in column 2, and so forth.

SUM (C, DIM=2) returns the value (6, 15), which is the sum of all elements in each row. 6 is the sum of 1 + 2 + 3 in row 1. 15 is the sum of 4 + 5 + 6 in row 2.

The following shows another example:

```
INTEGER array (2, 3), i, j(3)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
!  array is  1 3 5
!            2 4 6
i = SUM((/ 1, 2, 3 /))         ! returns 6
j = SUM(array, DIM = 1)        ! returns [3 7 11]
WRITE(*,*) i, j
END
```

PRODUCT

SYNC ALL

Statement: *Performs a synchronization of all images on the current team.*

Syntax

The SYNC ALL statement takes the following form:

```
SYNC ALL[([STAT=stat-var][, ERRMSG=err-var])]
```

stat-var	Is a scalar integer variable in which the status of the synchronization is stored.
err-var	Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC ALL statement.

Description

Execution on an image, for example, C, of the segment following the SYNC ALL statement is delayed until each other image has executed a SYNC ALL statement as many times as has image C.

The segments that executed before the SYNC ALL statement on an image, precede the segments that execute after the SYNC ALL statement on another image.

Example

In the following example, image 5 reads data and transmits the data to other images:

```
REAL :: W[*]
SYNC ALL
IF (THIS_IMAGE()==5) THEN
   READ (*,*) W
   DO I = 6, NUM_IMAGES()
      W[I] = W
   END DO
END IF
...
SYNC ALL
```

See Also

Image Control Statements
Coarrays
Using Coarrays

SYNC IMAGES

Statement: *Performs a synchronization of the image with each of the other images in the image set.*

Syntax

The SYNC IMAGES statement takes the following form:

SYNC IMAGES (*image-set*[, STAT=*stat-var*][, ERRMSG=*err-var*])

image-set	Is an integer expression or *. If it is an integer expression, it must be scalar or of rank one. If it is an array expression, the value of each element must be positive and not greater than the number of images; there must be no repeated values. If it is a scalar expression, the value must be positive and not greater than the number of images. If * is specified, it indicates all images.
stat-var	Is a scalar integer variable in which the status of the synchronization is stored.

err-var	Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC IMAGES statement.

Description

When SYNC IMAGES statements are executed on images C and G, they correspond if the number of times image C has executed a SYNC IMAGES statement in the current team with G in its image set is the same as the number of times image G has executed a SYNC IMAGES statement with C in its image set in this team. The segments that executed before the SYNC IMAGES statement on either image, precede the segments that execute after the corresponding SYNC IMAGES statement on the other image.

In a program that uses SYNC ALL as its only synchronization mechanism, every SYNC ALL statement can be replaced by a SYNC IMAGES (*) statement. However, SYNC ALL may provide better performance. SYNC IMAGES statements are not required to specify the entire image set, or even the same image set, on all images that participate in the synchronization.

Example

In the following example, image 5 waits for each of the other images to complete using the data. The other images wait for image 5 to set up the data, but do not wait for any other image:

```
IF (THIS_IMAGE() == 5) then
   SYNC IMAGES(*)       ! Sets up coarray data for other images
ELSE
   SYNC IMAGES(5)       ! Other images use the data set up by image 5
END IF
```

In the following example, each image synchronizes with its neighbor:

```
INTEGER :: THIS_STEP, TOTAL_STEPS, TOTAL_IMAGES, MY_IMAGE
MY_IMAGE = THIS_IMAGE ()
TOTAL_IMAGES = NUM_IMAGES ()
   ! Set up calculation
SYNC ALL

DO THIS_STEP = 1, TOTAL_STEPS
   IF (MY_IMAGE > 1) SYNC IMAGES (MY_IMAGE - 1)
      ! Do the calculations
   IF (MY_IMAGE < TOTAL_IMAGES) SYNC IMAGES (MY_IMAGE + 1)
END DO
SYNC ALL
```

The calculation starts on image 1 since all the others will be waiting on SYNC IMAGES (TOTAL_IMAGES-1). When this is done, image 2 starts and image 1 performs its second calculation. This continues until they are all executing different steps at the same time. Eventually, image 1 finishes and then the others finish one by one.

Coarrays
Using Coarrays

SYNC MEMORY

Statement: *Ends one image segment and begins another. Each segment can then be ordered in some way with respect to segments on other images.*

Syntax

The SYNC MEMORY statement takes the following form:

```
SYNC MEMORY [([STAT=stat-var][, ERRMSG=err-var])]
```

stat-var	Is a scalar integer variable in which the status of the synchronization is stored.
err-var	Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC IMAGES statement.

Description

Unlike the other image control statements, this statement does not have any built-in synchronization effect.

The action regarding X on image Q precedes the action regarding Y on image Q if, by execution of statements on image P, the following is true:

- A variable X on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement
- That statement precedes a successful execution of a SYNC MEMORY statement
- A variable Y on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement that succeeds execution of that SYNC MEMORY statement,

User-defined ordering of segment Pi on image P to precede segment Qj on image Q occurs when the following happens:

- Image P executes an image control statement that ends segment Pi, and then executes statements that initiate a cooperative synchronization between images P and Q
- Image Q executes statements that complete the cooperative synchronization between images P and Q and then executes an image control statement that begins segment Qj

Execution of the cooperative synchronization between images P and Q must include a dependency that forces execution on image P of the statements that initiate the synchronization to precede the execution on image Q of the statements that complete the synchronization. The mechanisms available for creating such a dependency are processor dependent.

> **NOTE**
> SYNC MEMORY usually suppresses compiler optimizations that may reorder memory operations across the segment boundary defined by the SYNC MEMORY statement. It ensures that all memory operations initiated in the preceding segments in its image complete before any memory operations in the subsequent segment in its image are started.

Example

The following example should be run on two images:

```
use, intrinsic :: iso_fortran_env
logical (atomic_logical_kind), save :: locked[*] = .true.
logical val
integer :: iam

iam = this_image()
```

```
if (iam == 1) then
   sync memory
   call atomic_define(locked[2], .false.)
else if (iam == 2) then
   val = .true.
   do while (val)
      call atomic_ref(val, locked)
   end do
   sync memory
end if

print *, 'success'
end
```

SYNC TEAM

Statement: *Performs a synchronization of all images on the specified team.*

Syntax

The SYNC TEAM statement takes the following form:

```
SYNC TEAM(team-value [, STAT = stat-var] [, ERRMSG = err-var])
```

team-value	Identifies the team to synchronize.
stat-var	(Optional) Is a scalar integer variable in which the status of the synchronization is stored.
err-var	(Optional) Is a scalar default character variable in which an error condition is stored if such a condition exists.

STAT= and ERR= can appear in any order, but each can appear at most once in a SYNC TEAM statement.

Description

A SYNC TEAM statement performs a synchronization of all images on the specified team. The team specified must be the current team or an ancestor team, or a team whose parent is the current team. The executing image must be a member of the specified team.

Execution of the segment following the SYNC TEAM statement is delayed on all images of the specified team until all images of the specified team have executed the same SYNC TEAM statement the same number of times.

A SYNC TEAM statement synchronizes a specific team, while a SYNC ALL statement synchronizes the current team.

Example

In the following example, two teams are created by the FORM TEAM statement. Team number 1 consists of the odd numbered images of the initial team; team number 2 consists of the even numbered images of the initial team.

The SYNC TEAM statement when executed by an odd numbered image on the initial team prevents all other odd numbered images of the initial team from proceeding to segment 2 until all odd images of the initial team have executed the SYNC TEAM statement. Similarly, all even numbered images of the initial team are prevented from executing segment 2 until all the even numbered images on the initial team have executed the SYNC TEAM statement.

Using a SYNC ALL statement would prevent all images of the initial team from executing segment 2 until all images had executed the SYNC ALL statement.

```
PROGRAM MAIN
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE) odd_even
FORM TEAM (2-MOD (THIS_IMAGE(), 2), odd_even)
   ! Segment 1
SYNC TEAM (odd_even)
   ! Segment 2
END PROGRAM
```

Coarrays
Using Coarrays

SYSTEM

Portability Function: *Sends a command to the shell as if it had been typed at the command line.*

Module

USE IFPORT

Syntax

`result = SYSTEM (string)`

string (Input) Character*(*). Operating system command.

Results

The result type is INTEGER(4). The result is the exit status of the shell command. If -1, use IERRNO to retrieve the error. Errors can be one of the following:

- E2BIG: The argument list is too long.
- ENOENT: The command interpreter cannot be found.
- ENOEXEC: The command interpreter file has an invalid format and is not executable.
- ENOMEM: Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Example

```
USE IFPORT
INTEGER(4) I, errnum
I = SYSTEM("dir > file.lst")
If (I .eq. -1) then
  errnum = ierrno( )
  print *, 'Error ', errnum
end if
END
```

SYSTEMQQ

SYSTEM_CLOCK

Intrinsic Subroutine: *Returns data from a real-time clock. SYSTEM_CLOCK returns the number of seconds from 00:00 Coordinated Universal Time (CUT) on 1 JAN 1970. The number is returned with no bias. To get the elapsed time, you must call SYSTEM_CLOCK twice, and subtract the starting time value from the ending time value.*

Syntax

CALL SYSTEM_CLOCK ([*count*] [, *count_rate*] [, *count_max*])

count	(Output; optional) Must be scalar and of type integer with a kind type parameter greater than 1. It is set to a value based on the current value of the processor clock. The value is increased by one for each clock count until the value *count_max* is reached, and is reset to zero at the next count. *count* lies in the range 0 to *count_max*.
count_rate	(Output; optional) Must be scalar and of type integer or real. It is set to the number of processor clock counts per second. If the type is INTEGER(1), *count_rate* is 0. If the type is INTEGER(2), *count_rate* is 1000. If the type is INTEGER(4) or REAL(4), *count_rate* is 10000. If the type is INTEGER(8), REAL(8), or REAL(16), *count_rate* is 1000000. If the *count* argument is also supplied, the value returned for *count_rate* is determined by the integer kind of *count*, not *count_rate*.
count_max	(Output; optional) Must be scalar and of type integer. It is set to the value HUGE(INT(0,KIND(*count*))).

If the type of *count_rate* or *count_max* is INTEGER(1), *count_rate* and *count_max* are zero, indicating that there is no clock available to Intel® Fortran with an 8-bit range. If *count* is INTEGER(1), a compile time message is issued indicating that the kind type is too small.

The values of *count_rate* and *count_max* are valid only for calls to SYSTEM_CLOCK where *count* is the same-sized integer (or INTEGER(8) for the case where *count_rate* is REAL(16)).

Example

Consider the following:

```
integer(2) :: ic2, crate2, cmax2
integer(4) :: ic4, crate4, cmax4
call system_clock(count=ic2, count_rate=crate2, count_max=cmax2)
```

```
call system_clock(count=ic4, count_rate=crate4, count_max=cmax4)
print *, ic2, crate2, cmax2
print *, ic4, crate4, cmax4
end
```

This program was run on Thursday Dec 11, 1997 at 14:23:55 EST and produced the following output:

```
 13880   1000  32767
 1129498807       10000  2147483647
```

DATE_AND_TIME
HUGE
GETTIM

SYSTEMQQ

Portability Function: *Executes a system command by passing a command string to the operating system's command interpreter.*

Module

USE IFPORT

Syntax

`result = SYSTEMQQ (commandline)`

commandline	(Input) Character*(*). Command to be passed to the operating system.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$2BIG - The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
- ERR$NOINT - The command interpreter cannot be found.
- ERR$NOEXEC - The command interpreter file has an invalid format and is not executable.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

The command line character limit for the SYSTEMQQ function is the same limit that your operating system command interpreter accepts.

Example

```
USE IFPORT
LOGICAL(4) result
result = SYSTEMQQ('copy c:\bin\fmath.dat &
                        c:\dat\fmath2.dat')
```

SYSTEM

T to Z

This section describes language features that start with T, U, V, W, X, Y, or Z.

T to Z

TAN

Elemental Intrinsic Function (Generic): *Produces the tangent of an argument in radians.*

Syntax

`result = TAN (x)`

x	(Input) Must be of type real or complex. If *x* is of type real, it must be in radians and is treated as modulo.

Results

The result type and kind are the same as *x*.

If *x* is of type real, the result is a value in radians.

If *x* is of type complex, the real part of the result is a value in radians.

Specific Name	Argument Type	Result Type
TAN	REAL(4)	REAL(4)
DTAN	REAL(8)	REAL(8)
QTAN	REAL(16)	REAL(16)
CTAN [1]	COMPLEX(4)	COMPLEX(4)
CDTAN [2]	COMPLEX(8)	COMPLEX(8)
CQTAN	COMPLEX(16)	COMPLEX(16)

[1]The setting of compiler options specifying real size can affect CTAN.

[2]This function can also be specified as ZTAN.

Example

TAN (2.0) has the value -2.185040.

TAN (0.8) has the value 1.029639.

TAND

Elemental Intrinsic Function (Generic): *Produces the tangent of an argument in degrees.*

Syntax

```
result = TAND (x)
```

x	(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

Results

The result type and kind are the same as *x*.

Specific Name	Argument Type	Result Type
TAND	REAL(4)	REAL(4)
DTAND	REAL(8)	REAL(8)
QTAND	REAL(16)	REAL(16)

Example

TAND (2.0) has the value 3.4920771E-02.

TAND (0.8) has the value 1.3963542E-02.

TANH

Elemental Intrinsic Function (Generic): *Produces a hyperbolic tangent.*

Syntax

```
result = TANH (x)
```

x	(Input) Must be of type real or complex.

Results

The result type and kind are the same as *x*.

If *x* is of type complex, the imaginary part of the result is in radians.

Specific Name	Argument Type	Result Type
TANH	REAL(4)	REAL(4)
DTANH	REAL(8)	REAL(8)
QTANH	REAL(16)	REAL(16)

Example

TANH (2.0) has the value 0.9640276.

TANH (0.8) has the value 0.6640368.

TARGET

OpenMP* Fortran Compiler Directive: *Creates a device data environment and executes the construct on that device. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END TARGET
-or-
!$OMP TARGET [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END TARGET]
```

clause

Is one or more of the following:

- ALLOCATE ([allocator :] list)
- DEFAULTMAP (*implicit-behavior*:SCALAR)

  Causes a scalar variable to be treated as if it appeared in a MAP clause with the *map-type* specified by *implicit-behavior*.

  The *implicit-behavior* can be ALLOC, TO, FROM, TOFROM, FIRSTPRIVATE, NONE, PRESENT, or DEFAULT. See MAP clause for a description of the ALLOC, TO, FROM, and TOFROM map types.

  If the *implicit-behavior* is DEFAULT, the clause has no effect for scalar variables.

  If the *implicit-behavior* is PRESENT, each scalar variable behaves as if it appeared in a MAP clause with a *map-type* of ALLOC and a *map-type-modifier* of PRESENT.

  If the *implicit-behavior* is NONE, a variable referenced in the TARGET construct that does not have a predetermined data scoping attribute must have appeared in a TO clause of a DECLARE TARGET directive, or it must appear in one of the following:

  - A data mapping attribute clause
  - A data scoping attribute clause, including a data scoping attribute clause of a combined construct where TARGET is one of the constructs of the combined construct

  If this clause is not specified, a scalar variable is not mapped; instead it has an implicit attribute of FIRSTPRIVATE. At most one DEFAULTMAP clause can appear in the directive.
- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- FIRSTPRIVATE (list)
- HAS_DEVICE_ADDR (*list*)

  Specifies variables that have device addresses and can be directly accessed by the target device. Each *list* item must have valid device address for the device data environment. You can specify an array section as a *list* item.

  If you access a *list* item whose device address is on a device other than the device that executes the TARGET construct, it causes undefined behavior.

A *list* item that appears in a HAS_DEVICE_ADDR clause cannot also appear in an IS_DEVICE_PTR clause in the same TARGET directive.

- IF ([TARGET:] scalar-logical-expression)
- IN_REDUCTION (reduction-identifier : list)
- IS_DEVICE_PTR (list)
- MAP ([[map-type-modifier[,]] map-type:] list)

  The *map-type* must be one of ALLOC, FROM, TO, or TOFROM.
- NOWAIT
- PRIVATE (list)
- SUBDEVICE ([integer-constant ,] integer-expression [: integer-expression [: integer-expression]])
- THREAD_LIMIT (scalar-integer-expression)

loosely-structured-block — Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block — Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding task for a TARGET construct is the encountering task. The target region binds to the enclosing parallel or task region.

This construct provides a superset of the functionality provided by the TARGET DATA construct, except for the clauses USE_DEVICE_PTR and USE_DEVICE_ADDR.

A *list* item in an IS_DEVICE_PTR clause that has a type other than C_PTR is the same as if it was a list item in a HAS_DEVICE_ADDR clause. List items specified in a IS_DEVICE_PTR or HAS_DEVICE_ADDR clause cannot appear in a data sharing attribute clause in the same TARGET directive. Note that the OpenMP* Specification has deprecated non-C_PTR type *list* items in an IS_DEVICE_PTR clause.

The TARGET construct also specifies that the region is executed by a device. The encountering task waits for the device to complete the target region at the end of the construct.

If a TARGET, TARGET DATA, or TARGET UPDATE construct appears within an OMP TARGET region, the construct is ignored.

Execution of the target task may be deferred if the NOWAIT clause is specified; if it is not specified, the target task is an included task.

IEEE floating-point halting, rounding modes, or exception flags set prior to the target region are undefined in the target region. Any that are set during execution of the target region become undefined upon exiting the target region.

Variables not declared in the target region, or specified in the TARGET directive, that are referenced in the target region must appear in a DECLARE TARGET directive.

The behavior is unspecified if a MAP clause list item is an array section derived from a variable with either the ALLOCATABLE or POINTER attribute and that variable is modified during the target region.

On entry to a target region, the following occurs:

- If a mapped ALLOCATABLE variable has a status of ALLOCATED, it has the status ALLOCATED at the start of the region, and its shape and allocation status cannot be modified in the region.
- If a mapped ALLOCATABLE variable has a status of UNALLOCATED, it has the allocation status UNALLOCATED at the start of the region, and upon exit from the region it must have a status of UNALLOCATED.
- If a mapped POINTER variable has the status ASSOCIATED, it must be associated with the same target upon exit from the region.
- If a mapped POINTER variable is DISASSOCIATED, its association at the start of the region is DISASSOCIATED, and it must have a DISASSOCIATED status at the end of the region.

In a target region, the association status of a procedure pointer is undefined unless it is used as the only argument to the ASSOCIATED function, in a pointer assignment statement, or in an indirect procedure call.

If a variable or part of a variable does not appear in an IN_REDUCTION clause and is mapped by the TARGET construct, the variable's default data-sharing attribute is shared in the data environment of the target task.

A variable that appears as a *list* item in an IN_REDUCTION clause is implicitly mapped as if it appears in a MAP clause with a *map-type* of TOFROM, and a *map-type-modifier* of ALWAYS.

A variable that is fully or partially mapped by the TARGET construct and that is not a *list* item in an IN_REDUCTION clause within the construct has a default data-sharing attribute of SHARED in the target tasks data environment.

If a variable appears in a REDUCTION or LASTPRIVATE clause in a combined TARGET construct, it is treated as if it had appeared in a MAP clause with a *map-type* of TOFROM for REDUCTION and a *map-type* of FROM for LASTPRIVATE:

```
! SUM is treated as MAP (TOFROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO REDUCTION(+:SUM)

! X is treated as MAP (FROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO LASTPRIVATE(X)
```

A non-scalar variable referenced in a target region and not explicitly mapped is implicitly treated as MAP (TOFROM):

```
INTEGER A(10)
!$OMP TARGET
  A(5) = 5          ! A is treated as MAP (TOFROM)
!$OMP  END TARGET
```

If only a subsection of a non-scalar variable has been mapped in an outer target region, and that variable is then mapped implicitly inside a nested target region, that variable should not access memory outside of the mapped subsection of the variable.

TARGET DATA
TARGET UPDATE
DECLARE TARGET
Parallel Processing Model for information about Binding Sets

TARGET DATA

OpenMP* Fortran Compiler Directive: *Maps variables to a device data environment for the extent of the region. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET DATA [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END TARGET DATA
-or-
!$OMP TARGET DATA [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END TARGET DATA]
```

clause	Is one or more of the following: • DEVICE (integer-expression) • IF ([TARGET DATA:] scalar-logical-expression) • MAP ([[map-type-modifier[,]] map-type:] list) • SUBDEVICE ([integer-constant ,] integer-expression [: integer-expression [: integer-expression]]) • USE_DEVICE_ADDR (list) • USE_DEVICE_PTR (ptr-list) At most one DEVICE clause and one IF clause can appear for the construct. At least one USE_DEVICE_PTR, USE_DEVICE_ADDR, or MAP clause must appear for the construct. The map-type in a MAP clause must be TO, FROM, TOFROM, or ALLOC.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding task region for a TARGET DATA construct is the encountering task. The target region binds to the enclosing parallel or task region.

When a TARGET DATA construct is encountered, a new device data environment is created, and the encountering task executes the target data region.

Occurrences of a list item appearing in a USE_DEVICE_ADDR clause in the structured block of the construct are references to the device address of the item if the item has corresponding storage in the device data environment. If the list item is not mapped, it is assumed to be accessible on the target device. The host storage of a list item that has a device address may not be accessible from within the structured block. List items can include array sections.

If a list item in a USE_DEVICE_PTR clause is not of type C_PTR from the intrinsic module ISO_C_BINDING, it is treated as if it appeared in a USE_DEVICE_ADDR clause. The use of non-C_PTR types in a USE_DEVICE_PTR clause has been deprecated.

A program must not depend on any ordering of the evaluations of the clauses of the TARGET DATA directive, or on any side effects of the evaluations of the clauses, except that list items in any MAP clause are data mapped prior to the conversion of any list items in a USE_DEVICE_PTR or USE_DEVICE_ADDR clause to their device storage locations within the structured block.

List items in USE_DEVICE_PTR and USE_DEVICE_ADDR clauses can not be specified more than once in the same or any other USE_DEVICE_PTR or USE_DEVICE_ADDR clause for the construct.

A list item in a USE_DEVICE_PTR or a USE_DEVICE_ADDR clause must not be a component of a derived type.

List items in a USE_DEVICE_ADDR clause must have been mapped to the device, or be accessible on the device from the host data environment. Similarly, the value of a list item in a USE_DEVICE_PTR that is of type C_PTR must be the address of an entity that has storage in the device data environment or that is accessible on the device from the host data environment.

If a list item in a USE_DEVICE_ADDR is an array section, the designator of the base expression cannot contain any construct association selectors.

The same variable can be used in both the MAP clause and the USE_DEVICE_PTR clause or a USE_DEVICE_ADDR clause:

```
!$OMP TARGET DATA MAP(X, Y) USE_DEVICE_PTR(X) USE_DEVICE_ADDR (Y)
    block
!$OMP END TARGET DATA
```

TARGET Statement

Statement and Attribute: *Specifies that an object can become the target of a pointer (it can be pointed to).*

Syntax

The TARGET attribute can be specified in a type declaration statement or a TARGET statement, and takes one of the following forms:

Type Declaration Statement:

type,[*att-ls*,] TARGET [, *att-ls*] :: *object* [(*a-spec*)] [[*coarray-spec*]] [, *object*[(*a-spec*)] [[*coarray-spec*]]]...

Statement:

TARGET [::] *object* [(*a-spec*)] [[*coarray-spec*]] [, *object*[(*a-spec*)]] [[*coarray-spec*]]...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
object	Is the name of the object. The object must not be declared with the PARAMETER attribute.
a-spec	(Optional) Is an array specification or a coarray specification.
coarray-spec	(Optional) Is a deferred-coshape specification. The left bracket and right bracket are required.

Description

A pointer is associated with a target by pointer assignment or by an ALLOCATE statement.

If an object does not have the TARGET attribute or has not been allocated (using an ALLOCATE statement), no part of it can be accessed by a pointer.

Example

The following example shows type declaration statements specifying the TARGET attribute:

```
TYPE(SYSTEM), TARGET :: FIRST
REAL, DIMENSION(20, 20), TARGET :: C, D
```

The following is an example of a TARGET statement:

```
TARGET :: C(50, 50), D
```

The following fragment is from the program POINTER2.F90 in the <install-dir>/samples subdirectory:

```
! An example of pointer assignment.
    REAL, POINTER :: arrow1 (:)
    REAL, POINTER :: arrow2 (:)
    REAL, ALLOCATABLE, TARGET :: bullseye (:)

    ALLOCATE (bullseye (7))
    bullseye = 1.
    bullseye (1:7:2) = 10.
    WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

    arrow1 => bullseye
    WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1
    . . .
```

TARGET ENTER DATA

OpenMP* Fortran Compiler Directive: *Specifies that variables are mapped to a device data environment. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET ENTER DATA [clause[[,] clause]... ]
```

clause — Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF ([TARGET ENTER DATA:] scalar-logical-expression)
- MAP ([[map-type-modifier[,]] map-type :] list)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [: integer-expression [: integer-expression]])

The binding task for the TARGET ENTER DATA construct is the encountering task. TARGET ENTER DATA is a stand-alone directive.

When a TARGET ENTER DATA construct is encountered, the *list* items in the MAP clauses are mapped to the device data environment according to *map-type*. If a *map-type* is specified in a MAP clause, it must be either TO or ALLOC. If no *map-type* is specified, it is as if TO appeared.

The TARGET ENTER DATA construct executes as if it was enclosed in a TASK construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit TASK construct that encloses the TARGET ENTER DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named `default-device-var`.

When an IF clause is present and the IF clause *scalar-logical-expression* evaluates to .FALSE., the device is the host.

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
TARGET EXIT DATA
Parallel Processing Model for information about Binding Sets

TARGET EXIT DATA

OpenMP* Fortran Compiler Directive: *Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET EXIT DATA [clause[[,] clause]... ]
```

clause — Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF ([TARGET EXIT DATA:] scalar-logical-expression)
- MAP ([[map-type-modifier[,]] map-type :] list)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [: integer-expression [: integer-expression]])

The binding task for the TARGET EXIT DATA construct is the encountering task. TARGET EXIT DATA is a stand-alone directive.

When a TARGET EXIT DATA construct is encountered, the *list* items in the MAP clauses are unmapped from the device data environment according to *map-type*. If a *map-type* is specified in a MAP clause, it must be FROM, RELEASE, or DELETE. If *map-type* is not specified, it is as if FROM appeared.

The TARGET EXIT DATA construct executes as if it was enclosed in a task construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit task construct that encloses the TARGET EXIT DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named `default-device-var`.

When an IF clause is present and the IF clause *scalar-logical-expression* evaluates to .FALSE., the device is the host.

Parallel Processing Model for information about Binding Sets

TARGET PARALLEL

OpenMP* Fortran Compiler Directive: *Creates a device data environment in a parallel region and executes the construct on that device.*

Syntax

```
!$OMP TARGET PARALLEL [clause[[,] clause] ... ]
```

```
      loosely-structured-block
!$OMP END TARGET PARALLEL
-or-
!$OMP TARGET PARALLEL [clause[[,] clause] ... ]
      strictly-structured-block
[!$OMP END TARGET PARALLEL]
```

clause	Can be any of the clauses accepted by the TARGET or PARALLEL directives with identical meanings and restrictions.
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a PARALLEL construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately. The only exceptions are the following:

- If any IF clause in the directive includes a *directive-name-modifier* then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no *directive-name-modifier* can appear on the directive.
- At most one IF clause with the PARALLEL *directive-name-modifier* can appear on the directive.
- At most one IF clause with the TARGET *directive-name-modifier* can appear on the directive.

Syntax Rules for Compiler Directives
IF Clause
TARGET Directive
PARALLEL Directive

TARGET PARALLEL DO

OpenMP* Fortran Compiler Directive: *Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.*

Syntax

```
!$OMP TARGET PARALLEL DO [clause[[,] clause] ... ]
      do-loop
[!$OMP END TARGET PARALLEL DO]
```

clause	Can be any of the clauses accepted by the TARGET or PARALLEL DO directives, except for the COPYIN clause.
do-loop	Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. You cannot branch out of a DO loop associated with a DO directive.

If the END TARGET PARALLEL DO directive is not specified, the TARGET PARALLEL DO is assumed at the end of *do-loop*. If used, the END TARGET PARALLEL DO directive must appear immediately after the end of *do-loop*.

The semantics are identical to explicitly specifying a TARGET directive immediately followed by a PARALLEL DO directive.

The restrictions for the TARGET and PARALLEL DO constructs apply to this directive except for the following:

- If any IF clause in the directive includes a *directive-name-modifier* then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no *directive-name-modifier* can appear on the directive.
- At most one IF clause with the PARALLEL *directive-name-modifier* can appear on the directive.
- At most one IF clause with the TARGET *directive-name-modifier* can appear on the directive.

IF Clause
TARGET Directive
PARALLEL DO

TARGET PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: *Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.*

Syntax

```
!$OMP TARGET PARALLEL DO SIMD [clause[[,] clause] ... ]
      do-loop
[!$OMP END TARGET PARALLEL DO SIMD]
```

clause	Can be any of the clauses accepted by the TARGET or PARALLEL DO SIMD directives, except for the COPYIN clause.
do-loop	Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops. The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team. You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET PARALLEL DO SIMD directive is not specified, an END TARGET PARALLEL DO SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and PARALLEL DO SIMD constructs apply to this directive except for the following:

- If any IF clause in the directive includes a directive-name-modifier then all IF clauses in the directive must include a directive-name-modifier.

- At most one IF clause with no directive-name-modifier can appear on the directive.
- At most one IF clause with the PARALLEL directive-name-modifier can appear on the directive.
- At most one IF clause with the TARGET directive-name-modifier can appear on the directive.

IF Clause
TARGET Directive
PARALLEL DO SIMD

TARGET PARALLEL LOOP

OpenMP* Fortran Compiler Directive: *Specifies a shortcut for specifying a parallel loop inside a TARGET construct that contains no other statements than the parallel loop. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET PARALLEL LOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END TARGET PARALLEL LOOP]
```

clause	Can be any of the clauses accepted by the TARGET or PARALLEL LOOP constructs with identical meanings and restrictions.
do-loop	Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer. The loop can be a DO CONCURRENT loop, subject to the rules specified for variables referenced in a DO CONCURRENT loop associated with LOOP and PARALLEL constructs.

This combined directive is semantically equivalent to a TARGET directive followed immediately by a PARALLEL LOOP construct. The restrictions for TARGET and PARALLEL LOOP constructs apply to this combined construct.

If used, the END TARGET PARALLEL LOOP directive must appear immediately after the end of the loop. If you do not specify an END TARGET PARALLEL LOOP directive, an END TARGET PARALLEL LOOP directive is assumed at the end of the *do-loop*.

If *do-loop* is a DO CONCURRENT loop, a variable that has SHARED locality in the DO CONCURRENT loop is treated as if it appears in a MAP clause with *map-type* TOFROM.

TARGET SIMD

OpenMP* Fortran Compiler Directive: *Specifies a TARGET construct that contains a SIMD construct and no other statement.*

Syntax

```
!$OMP TARGET SIMD [clause[[,] clause] ... ]
      do-loop
[!$OMP END TARGET SIMD]
```

clause	Can be any of the clauses accepted by the TARGET or SIMD directive, with identical meanings and restrictions
do-loop	Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops. The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team. You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET SIMD directive is not specified, an END TARGET SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and SIMD constructs apply to this directive.

TARGET TEAMS

OpenMP* Fortran Compiler Directive: *Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.*

Syntax

```
!$OMP TARGET TEAMS [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END TARGET TEAMS
-or-
!$OMP TARGET TEAMS [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END TARGET TEAMS]
```

clause	Can be any of the clauses accepted by the TARGET or TEAMS directives with identical meanings and restrictions.

loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a TEAMS construct.

TARGET TEAMS DISTRIBUTE

OpenMP* Fortran Compiler Directive: *Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a TEAMS construct.*

Syntax

```
!$OMP TARGET TEAMS DISTRIBUTE [clause[[,] clause]... ]
   do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE]
```

clause	Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE directives with identical meanings and restrictions.
do-loop	Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops. The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE construct.

If the END TARGET TEAMS DISTRIBUTE directive is not specified, an END TARGET TEAMS DISTRIBUTE directive is assumed at the end of *do-loop*.

TARGET TEAMS DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: *Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.*

Syntax

```
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO [clause[[,] clause]... ]
   do-loop
[!$OMP END TARGET TEAMS DISTRIBUTE PARALLEL DO]
```

clause	Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE PARALLEL DO directives with identical meanings and restrictions.
do-loop	Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer. All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops. The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE PARALLEL DO construct.

If the END TARGET TEAMS DISTRIBUTE PARALLEL DO directive is not specified, an END TARGET TEAMS DISTRIBUTE PARALLEL DO directive is assumed at the end of *do-loop*.

TEAMS DISTRIBUTE SIMD

TARGET TEAMS LOOP

OpenMP* Fortran Compiler Directive: *Specifies a shortcut for specifying a TEAMS LOOP construct inside a TEAMS construct that contains no other statements. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET TEAMS LOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END TARGET TEAMS LOOP]
```

clause — Can be any of the clauses accepted by the TARGET or TEAMS LOOP directives with identical meanings and restrictions.

do-loop — Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer.

The loop can be a DO CONCURRENT loop, subject to the rules specified for variables referenced in a DO CONCURRENT loop associated with LOOP and TEAMS constructs.

This combined directive is semantically equivalent to a TEAMS LOOP construct that immediately follows a TARGET directive. All restrictions for TARGET and TEAMS LOOP constructs apply to this combined construct.

If used, the END TARGET TEAMS LOOP directive must appear immediately after the end of the loop. If you do not specify an END TARGET TEAMS LOOP directive, an END TARGET TEAMS LOOP directive is assumed at the end of the *do-loop*.

If *do-loop* is a DO CONCURRENT loop, a variable that has SHARED locality in the DO CONCURRENT loop is treated as if it appears in a MAP clause with *map-type* TOFROM.

TARGET UPDATE

OpenMP* Fortran Compiler Directive: *Makes the list items in the device data environment consistent with their corresponding original list items. This feature is only available for ifx.*

Syntax

```
!$OMP TARGET UPDATE motion-clause [, clause[[,] clause]... ]
```

motion-clause

Is one of the following:

- FROM ([MAPPER (*map-identifier*) :] *list*)
- TO ([MAPPER (*map-identifier*) :] *list*)

The *map-identifier* must be an accessible *map-identifier* that is given a user-defined mapper in a DECLARE MAPPER directive. If MAPPER is not present, it is as if MAPPER (DEFAULT) was specified. An accessible user-defined mapper with the same *map-identifier* that is specified in the MAPPER *motion-clause* modifies the mapping of a *list* item with the same type as the user-defined mapper.

If the *motion-clause* is TO, each *list* item is replaced with the *list* items that the specified mapper indicates are to be mapped with a TO or TOFROM map type. Similarly, if the *motion-clause* is FROM, each *list* item is replaced with *list* items that the specified mapper indicates are to be mapped with a FROM or TOFROM map type.

The *list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /). A *list* item can be a strided array section.

For each *list* item in a TO or FROM clause, there is a corresponding list item and an original list item; for more information, see the MAP clause. Note that if the corresponding list item is not present in the device data environment, the behavior is unspecified.

For each *list* item in a TO clause, the value of the original list item is assigned to the corresponding list item.

For each *list* item in a FROM clause, the value of the corresponding list item is assigned to the original list item.

A *list* item or subobject of a *list* item that has the ALLOCATABLE attribute is updated only if it is allocated. A *list* item that has the POINTER attribute whose association status is associated, the update is performed with respect to the pointer target

A *list* item can only appear in a TO or FROM clause, but not both.

clause

Is one of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)

  At most one DEVICE clause can be specified.
- IF ([TARGET UPDATE:] scalar-logical-expression)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [: integer-expression [: integer-expression]])

The binding task for a TARGET UPDATE construct is the encountering task. The TARGET UPDATE directive is a stand-alone directive.

A TARGET UPDATE construct must not appear inside of a target region.

Parallel Processing Model for information about Binding Sets

TASK

OpenMP* Fortran Compiler Directive: *Defines a task region.*

Syntax

```
!$OMP TASK [clause[[,] clause] ... ]
   block
[!$OMP END TASK]
```

clause	Is one of the following: • ALLOCATE ([allocator :] list) • DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE) • DEPEND (dependence-type : list) • FINAL (scalar-logical-expression) • FIRSTPRIVATE (list) • IF ([TASK:] scalar-logical-expression) • IN_REDUCTION (reduction-identifier : list) • MERGEABLE • PRIORITY (priority-value) • PRIVATE (list) • SHARED (list) • UNTIED
block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The binding thread set of a TASK construct is the current team. A task region binds to the innermost enclosing parallel region.

The TASK and END TASK directive pair must appear in the same routine in the executable section of the code.

The END TASK directive denotes the end of the task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The encountering thread may immediately execute the task, or defer its execution. In the latter case, any thread in the team may be assigned the task.

A thread that encounters a task scheduling point within the task region may temporarily suspend the task region. By default, a task is then tied and its suspended task region can only be resumed by the thread that started its execution. However, if the untied clause is specified in a TASK construct, any thread in the team can resume the task region after a suspension. The untied clause is ignored in these cases:

- If a final clause has been specified in the same TASK construct and the final clause expression evaluates to .TRUE..
- If a task is an included task.

A TASK construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

The TASK construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion. An implementation may add task scheduling points anywhere in untied task regions.

Note that when storage is shared by an explicit task region, you must add proper synchronization to ensure that the storage does not reach the end of its lifetime before the explicit task region completes its execution.

A program must not depend on any ordering of the evaluations of the clauses of the TASK directive and it must not depend on any side effects of the evaluations of the clauses. A program that branches into or out of a task region is non-conforming.

Unsynchronized use of Fortran I/O statements by multiple tasks on the same unit has unspecified behavior.

NOTE
This construct is not supported within a TARGET or a DECLARE TARGET region if the target hardware is spir64.

Examples

The following example calculates a Fibonacci number. The Fibonacci sequence is 1,1,2,3,5,8,13, etc., where the current number is the sum of the previous two numbers. If a call to function fib is encountered by a single thread in a parallel region, a nested task region will be spawned to carry out the computation in parallel.

```
RECURSIVE INTEGER FUNCTION fib(n)
INTEGER n, i, j
IF ( n .LT. 2) THEN
  fib = n
ELSE
  !$OMP TASK SHARED(i)
     i = fib( n-1 )
  !$OMP END TASK
  !$OMP TASK SHARED(j)
     j = fib( n-2 )
  !$OMP END TASK
  !$OMP TASKWAIT      ! wait for the sub-tasks to
                            !   complete before summing
     fib = i+j
END IF
END FUNCTION
```

The following example generates a large number of tasks in one thread and executes them with the threads in the parallel team. While generating these tasks, if the implementation reaches the limit generating unassigned tasks, the generating loop may be suspended and the thread used to execute unassigned tasks. When the number of unassigned tasks is sufficiently low, the thread resumes execution of the task generating loop.

```
real*8 item(10000000)
integer i
!$omp parallel
!$omp single     ! loop iteration variable i is private
    do i=1,10000000
```

```
!$omp task
! i is firstprivate, item is shared
    call process(item(i))
!$omp end task
    end do
!$omp end single
!$omp end parallel
end
```

The following example modifies the previous one to use an untied task to generate the unassigned tasks. If the implementation reaches the limit generating unassigned tasks and the generating loop is suspended, any other thread that becomes available can resume the task generation loop.

```
real*8 item(10000000)
!$omp parallel
!$omp single!
$omp task untied
! loop iteration variable i is private
    do i=1,10000000
!$omp task     ! i is firstprivate, item is shared
    call process(item(i))
!$omp end task
    end do
!$omp end task
!$omp end single
!$omp end parallel
```

The following example demonstrates four tasks with dependences:

```
integer :: a

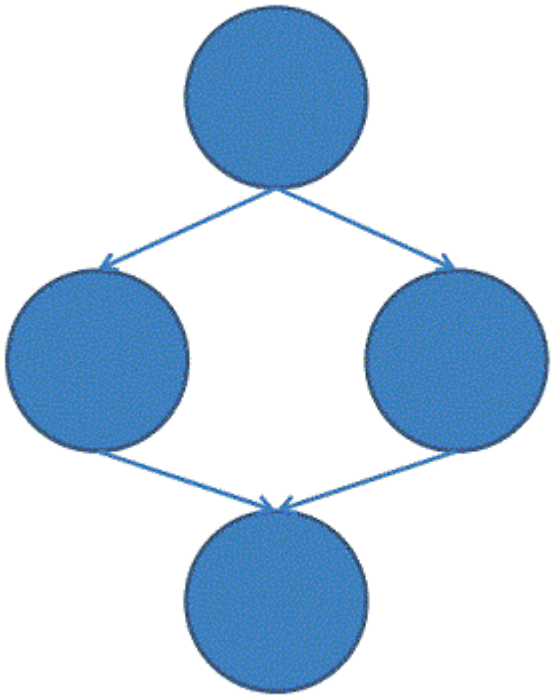
!$omp task depend(out:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(out:a)
!$omp end task
```

In the above example, the first task does not depend on any previous one. The second and third tasks depend on the first task but not on each other. The last task depends on the second and third tasks. The following shows the dependency graph:



The following example shows a set of sibling tasks that have dependences between them:

```
INTEGER :: A(0:N*B-1)

DO I=0,N-1
!$OMP TASK DEPEND(OUT:A(I*B:(I+1)*B-1))
      CALL FILL(A(I*B:(I+1)*B-1))
!$OMP END TASK
END DO

DO I=1,N-1
      IB = (I-1)*B+1
      BB = I*B+1
!$OMP TASK DEPEND(INOUT:A(I*B:(I+1)*B-1)) DEPEND(IN:A((I+1)*B:(I+2)*B-1))
      CALL PROCESS(A(I*B:(I+1)*B-1), A((I+1)*B:(I+2)*B-1))
!$OMP END TASK
END DO

DO I=1,N
      IB = (I-1)*B+1
!$OMP TASK DEPEND(IN:A(I*B:(I+1)*B-1))
      CALL OUTPUT(A(I*B:(I+1)*B-1))
!$OMP END TASK
END DO
```

In the above example, the tasks of the first loop will be independent of any other tasks since there is no previous task that expresses a dependence on the same list items. Tasks of the second loop will depend on two tasks from the first loop. Also, because dependences are constructed in a sequential order, the IN dependences force the tasks of the second loop to be dependent on the task from the previous iteration to be processed. Finally, tasks of the third loop can be executed when the corresponding Process task from the second loop has been executed. For example, if N was 4, the following shows the dependency graph:

SHARED Clause
Parallel Processing Model for information about Binding Sets

TASK_REDUCTION

Specifies a reduction among tasks. The TASK_REDUCTION clause is a reduction scoping clause.

Syntax

```
TASK_REDUCTION (reduction-identifier : list)
```

Arguments *reduction-identifier* and *list* are defined in REDUCTION clause. All the common restrictions for the REDUCTION clause apply to this clause.

See Also

IN_REDUCTION
DECLARE REDUCTION
REDUCTION
TASKGROUP

TASKGROUP

OpenMP* Fortran Compiler Directive: *Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.*

Syntax

```
!$OMP TASKGROUP [clause[[,] clause] ... ]
   loosely-structured-block
!$OMP END TASKGROUP
-or-
!$OMP TASKGROUP [clause[[,] clause] ... ]
   strictly-structured-block
[!$OMP END TASKGROUP]
```

clause	Is one of the following: • ALLOCATE ([allocator :] list) • TASK_REDUCTION (reduction-identifier : list)
loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

A TASKGROUP construct binds to the current task region. The binding thread set of the taskgroup region is the current team.

When a thread encounters a TASKGROUP construct, it starts executing the region. There is an implicit task scheduling point at the end of the TASKGROUP region. The current task is suspended at the task scheduling point until all child tasks that it generated in the TASKGROUP region and all of their descendant tasks complete execution.

Any number of reduction clauses can be specified in the TASKGROUP directive, but a list item can appear only once in reduction clauses for that directive.

Parallel Processing Model for information about Binding Sets

TASKLOOP

OpenMP* Fortran Compiler Directive: *Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.*

Syntax

```
!$OMP TASKLOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END TASKLOOP]
```

clause

Is one of the following:

- ALLOCATE ([allocator :] list)
- COLLAPSE (n)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- FINAL (scalar-logical-expression)
- FIRSTPRIVATE (list)
- GRAINSIZE ([STRICT:] *grain-size*)

  Specifies that the number of logical loop iterations assigned to each created task is greater than or equal to the minimum of the value of the *grain-size* positive integer expression and the number of logical loop iterations, but less than two times the value of the *grain-size* expression.

  STRICT is only permitted for ifx.

  If STRICT is specified, each generated task is exactly *grain-size*, except for the task that contains the sequentially last iterations, which may have fewer iterations.

  At most one GRAINSIZE clause can appear in a TASKLOOP directive.
- IF ([TASKLOOP:] *scalar-logical-expression*)

  If the *scalar-logical-expression* evaluates to false, undeferred tasks are generated. If a variable appears in the IF clause expression, it causes an implicit reference to the variable in all enclosing constructs.

  At most one IF clause can appear in a TASKLOOP directive.
- IN_REDUCTION (reduction-identifier : list)
- LASTPRIVATE ([CONDITIONAL:] list)
- MERGEABLE
- NOGROUP

Specifies that no implicit taskgroup region is created.

- NUM_TASKS ([STRICT:] *num-tasks*)

  Causes the TASKLOOP construct to create as many tasks as the minimum of the *num-tasks* positive scalar integer expression and the number of logical loop iterations. Each task must have at least one logical loop iteration.

  STRICT is only permitted for ifx.

  If STRICT is specified, a loop with *N* iterations is partitioned such that each task is assigned *N* / *num-tasks* iterations. If *num-tasks* does not divide *N* evenly, the last task is assigned a partition of size MOD (*num-tasks*, *N*).
- PRIORITY (priority-value)
- PRIVATE (list)
- REDUCTION ([DEFAULT,] reduction-identifier : list)

  If you specify this clause, you cannot specify the NOGROUP clause.
- SHARED (list)
- UNTIED

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

If an END TASKLOOP directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The TASKLOOP construct inherits the restrictions of the loop construct.

If any of the loop iteration variables would otherwise be shared, they are implicitly made private for the loop-iteration tasks created by the TASKLOOP construct. Unless the loop iteration variables are specified in a LASTPRIVATE clause on the TASKLOOP construct, their values after the loop are unspecified.

You cannot branch out of a DO loop associated with a TASKLOOP directive.

If you do not specify GRAINSIZE or NUM_TASKS, the number of loop tasks created and the number of logical loop iterations assigned to these tasks is implementation defined. The GRAINSIZE clause and NUM_TASKS clauses are mutually exclusive; they *cannot* appear in the same TASKLOOP directive.

The binding thread set of the TASKLOOP region is the current team. A TASKLOOP region binds to the innermost enclosing parallel region.

When a thread encounters a TASKLOOP construct, the construct partitions the associated loops into tasks for parallel execution of the loop iterations. The data environment of the created tasks is created according to the clauses specified in the TASKLOOP construct, any data environment ICVs, and any defaults that apply. The order of the creation of the loop tasks is unspecified. Programs that rely on any execution order of the logical loop iterations are non-conforming.

If used, the END TASKLOOP directive must appear immediately after the end of the loop. If you do not specify an END TASKLOOP directive, an END TASKLOOP directive is assumed at the end of the *do-loop*.

By default, the TASKLOOP construct executes as if it was enclosed in a TASKGROUP construct with no statements or directives outside of the TASKLOOP construct. Therefore, the TASKLOOP construct creates an implicit TASKGROUP region.

When a REDUCTION clause appears in a TASKLOOP construct, it behaves as if a TASK_REDUCTION clause was applied to the implicit TASKGROUP construct enclosing the TASKLOOP construct. For each task that is generated by the TASKLOOP construct, an IN_REDUCTION clause with the same *reduction-identifier* and the same *list* items that appear in the REDUCTION clause is applied to the task. Each generated task participates in the reduction defined by the IN_REDUCTION clause applied to the implicit TASKGROUP construct.

When an IN_REDUCTION clause appears in a TASKLOOP construct, an IN_REDUCTION clause with the same *reduction-identifier* and the same *list* items of the IN_REDUCTION clause is applied to the generated tasks. The behavior is the same as if each generated task was defined by a TASK construct that contains an IN_REDUCTION clause with the same *reduction-identifier* and *list* items. The generated tasks participate in a reduction defined by a previous *reduction scoping clause*.

A *list* item must not appear in both a REDUCTION and IN_REDUCTION clause in the same TASKLOOP directive.

The following restrictions also apply:

- A program that branches into or out of a TASKLOOP region is non-conforming.
- All loops associated with the TASKLOOP construct must be perfectly nested. There must be no intervening code nor any other OpenMP* directive between any two loops.

NOTE
This construct is not supported within a TARGET or a DECLARE TARGET region if the target hardware is spir64.

TASK_REDUCTION

TASKLOOP SIMD

OpenMP* Fortran Compiler Directive: *Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.*

Syntax

```
!$OMP TASKLOOP SIMD [clause[[,] clause]... ]
   do-loop
[!$OMP END TASKLOOP SIMD]
```

clause — Can be almost all of the clauses accepted by the TASKLOOP or SIMD directives with identical meanings and restrictions.

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team. You cannot branch out of a DO loop associated with a TASKLOOP directive.

If the END TASKLOOP SIMD directive is not specified, an END TASKLOOP SIMD directive is assumed at the end of do-loop.

The binding thread set of the TASKLOOP SIMD region is the current team. A TASKLOOP SIMD region binds to the innermost enclosing parallel region.

The TASKLOOP SIMD construct first distributes the iterations of the associated loops across tasks in a manner consistent with any clauses that apply to the TASKLOOP construct. The resulting tasks are then converted to SIMD loops in a manner consistent with any clauses that apply to the SIMD construct.

The effect of any clause that applies to both constructs is as if it were applied to both constructs separately, except for the COLLAPSE clause. For the purpose of converting each task to a SIMD loop, the COLLAPSE directive is ignored, and an IN_REDUCTION clause behaves as if a REDUCTION clause, with the same *reduction-identifier* and *list* items, is applied to the SIMD construct.

This directive specifies a composite construct.

Syntax Rules for Compiler Directives

TASKWAIT

OpenMP* Fortran Compiler Directive: *Specifies a wait on the completion of child tasks generated since the beginning of the current task.*

Syntax

```
!$OMP TASKWAIT [clause[[,] clause]...]
```

clause

Is only allowed for ifx. It is one or more of the following:

- DEPEND (dependence-type : list)

  The *dependence-type* MUTEXINOUTSET cannot be specified in a TASKWAIT directive. If *dependence-type* is DEPOBJ, the dependence object list items cannot have values that represent the MUTEXINOUTSET dependence type.
- NOWAIT

  This clause can only be specified if at least one DEPEND clause is also specified.

  Only one NOWAIT clause can be specified in a TASKWAIT directive.

A TASKWAIT construct binds to the current task region. The binding thread set of the taskwait region is the current team.

When the DEPEND clause is not specified, the current task region is suspended at an implicit scheduling point in the construct until the child tasks that the current task generated prior to the TASKWAIT have completed execution.

A TASKWAIT construct with one or more DEPEND clauses and a NOWAIT clause behaves as if the clauses were applied to a TASK construct with an empty structured block that generates a task whose execution is deferred until all preceding tasks of the current task complete execution before subsequently generated tasks that depend on this task begin execution.

A TASKWAIT construct with one or more DEPEND clauses and *no* NOWAIT clause behaves as if the DEPEND clauses were applied to a TASK construct with an empty structured block that generates an included and mergeable task. The current task is suspended until the preceding tasks of the current task complete execution.

Syntax Rules for Compiler Directives
TASK directive
TASKYIELD directive
Parallel Processing Model for information about Binding Sets

TASKYIELD

OpenMP* Fortran Compiler Directive: *Specifies that the current task can be suspended at this point in favor of execution of a different task.*

Syntax

```
!$OMP TASKYIELD
```

A taskyield region binds to the current task region. The binding thread set of the taskyield region is the current team.

Because the TASKYIELD construct is a stand-alone directive, there are some restrictions on its placement within a program:

- The TASKYIELD directive can only be placed at a point where a Fortran executable statement is allowed.
- The TASKYIELD directive cannot be used as the action statement in an IF statement or as the executable statement following a label if the label is referenced in the program.

The TASKYIELD construct includes an explicit task scheduling point in the current task region.

Example

The following example shows use of the TASKYIELD directive. It is non-conforming, because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are stand-alone directives and cannot be the action statement of an IF statement or a labeled branch target.

```
SUBROUTINE NONCONFORMING_STANDALONE()
   INTEGER A
   A = 1
   ! the FLUSH directive must not be the action statement in an IF statement
   !
   IF (A .NE. 0) !$OMP FLUSH(A)

   ! the BARRIER directive must not be the action statement in an IF statement
   !
   IF (A .NE. 0) !$OMP BARRIER

   ! the TASKWAIT directive must not be the action statement in an IF statement
   !
   IF (A .NE. 0) !$OMP TASKWAIT

   ! the TASKYIELD directive must not be the action statement in an IF statement
   !
   IF (A .NE. 0) !$OMP TASKYIELD

   GOTO 100
```

```
   ! the FLUSH directive must not be a labeled branch target statement
   !
   100 !$OMP FLUSH(A)
   GOTO 200

   ! the BARRIER directive must not be a labeled branch target statement
   !
   200 !$OMP BARRIER
   GOTO 300

   ! the TASKWAIT directive must not be a labeled branch target statement
   !
   300 !$OMP TASKWAIT
   GOTO 400

   ! the TASKYIELD directive must not be a labeled branch target statement
   !
   400 !$OMP TASKYIELD
END SUBROUTINE
```

The following version of the above example is conforming because the FLUSH, BARRIER, TASKWAIT, and TASKYIELD directives are enclosed in a compound statement.

```
SUBROUTINE CONFORMING_STANDALONE ()
   INTEGER N
   N = 1
   IF (N .NE. 0) THEN
       !$OMP FLUSH(N)
   ENDIF
   IF (N .NE. 0) THEN
       !$OMP BARRIER
   ENDIF
   IF (N .NE. 0) THEN
       !$OMP TASKWAIT
   ENDIF
   IF (N .NE. 0) THEN
       !$OMP TASKYIELD
   ENDIF
   GOTO 100
   100 CONTINUE
   !$OMP FLUSH(N)
   GOTO 200
   200 CONTINUE
   !$OMP BARRIER
   GOTO 300
   300 CONTINUE
   !$OMP TASKWAIT
   GOTO 400
   400 CONTINUE
   !$OMP TASKYIELD
END SUBROUTINE
```

TEAM_NUMBER

Transformational Intrinsic Function (Generic): *Returns the team number of the specified team.*

Syntax

```
result = TEAM_NUMBER ([ team ])
```

team	(Optional, Input) Must be of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV, with a value that describes the current team or an ancestor team. If *team* is not specified, the team is the current team.

Results

The result is an integer scalar whose value is -1 if the specified team is the initial team; otherwise, it is the positive integer value that identifies the team of the executing image in the set of teams described by the *team*.

Example

Consider the following program:

```
PROGRAM main
USE, INTRINSIC       :: ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)     :: original, odd_even
original = GET_TEAM (CURRENT_TEAM)
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
CHANGE TEAM (odd_even)
  . . .
  IF((THIS_IMAGE()==1).AND. (TEAM_NUMBER()==2) THEN
    PRINT *, TEAM_NUMBER(original)
    PRINT *, TEAM_NUMBER()
  END IF
  . . .
END TEAM
END PROGRAM

The output of the print statements will be
  -1
   2
```

The above output assumes there are at least two images in the initial team.

See Also

CHANGE TEAM

TEAMS

OpenMP* Fortran Compiler Directive: *Creates a league of thread teams to execute a structured block in the primary thread of each team. This feature is only available for ifx.*

Syntax

```
!$OMP TEAMS [clause[[,] clause]... ]
   loosely-structured-block
!$OMP END TEAMS
```

-or-

```
!$OMP TEAMS [clause[[,] clause]... ]
   strictly-structured-block
[!$OMP END TEAMS]
```

clause

Is one of the following:

- ALLOCATE ([allocator :] list)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- FIRSTPRIVATE (list)
- NUM_TEAMS (*scalar-integer-expression*)

  Specifies the number of teams to be used in a parallel region. The *scalar-integer-expression* must evaluate to a positive scalar integer value.

  Only a single NUM_TEAMS clause can appear in the directive.
- PRIVATE (list)
- REDUCTION ([DEFAULT,] reduction-identifier : list)
- SHARED (list)
- THREAD_LIMIT (scalar-integer-expression)

loosely-structured-block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block

Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a TEAMS construct is the encountering thread.

If a TEAMS construct appears within a TARGET construct, the enclosing TARGET construct must contain no other statements or directives outside of the TEAMS construct. The following are the only OpenMP* constructs that can be nested in the team's region:

- DISTRIBUTE
- PARALLEL
- PARALLEL SECTIONS
- PARALLEL WORKSHARE
- PARALLEL DO
- PARALLEL DO SIMD

The thread that encounters this directive constructs a league of thread teams that execute the *block* in the primary thread of each team. After the teams are created, the number of teams remains constant for the duration of the team's parallel region.

The region following the TEAMS construct is executed by the primary thread of each team. Other threads do not begin execution until the primary thread encounters a parallel region. After the teams complete execution of the TEAMS construct region, the encountering thread resumes execution of the enclosing target region.

If NUM_TEAMS is not specified, the default number of teams is one. If THREAD_LIMIT is not specified, the default number of threads is *the-number-of-available-hardware-threads* / NUM_TEAMS.

A program must not depend on any side effects or any ordering of the evaluation of clauses in the TEAMS directive.

Each team has a unique team number. You can use the OpenMP* runtime library routine OMP_GET_TEAM_NUM to get the team number of the calling thread.

Each thread within the team has a unique thread identifier returned by the OpenMP runtime library routine OMP_GET_THREAD_NUM. As in any thread team, the thread identifier starts at zero for the primary thread up to THREAD_LIMIT - 1 for the remaining threads.

Immediately after this directive, only the primary threads in each team are executing, the other team members will only start to execute at the next (nested) parallel region. Therefore, there are only NUM_TEAMS threads executing, and each of them has OMP_GET_THREAD_NUM() == 0.

A variable with LOCAL_INIT or SHARED locality in a DO CONCURRENT statement associated with a LOOP directive that binds to the teams region of this construct cannot appear in a PRIVATE or FIRST_PRIVATE clause in the TEAMS directive.

TEAMS DISTRIBUTE

OpenMP* Fortran Compiler Directive: *Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a TEAMS construct.*

Syntax

```
!$OMP TEAMS DISTRIBUTE [clause[[,] clause]... ]
   do-loop
[!$OMP END TEAMS DISTRIBUTE]
```

clause — Can be any of the clauses accepted by the TEAMS or DISTRIBUTE directives with identical meanings and restrictions.

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct containing a DISTRIBUTE construct.

If the END TEAMS DISTRIBUTE directive is not specified, an END TEAMS DISTRIBUTE directive is assumed at the end of *do-loop*.

Syntax Rules for Compiler Directives

TEAMS DISTRIBUTE PARALLEL DO

OpenMP* Fortran Compiler Directive: *Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.*

Syntax

```
!$OMP TEAMS DISTRIBUTE PARALLEL DO [clause[[,] clause]... ]
   do-loop
[!$OMP END TEAMS DISTRIBUTE PARALLEL DO]
```

clause — Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO directives with identical meanings and restrictions.

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO construct. Some clauses are permitted on both constructs.

If the END TEAMS DISTRIBUTE PARALLEL DO directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO directive is assumed at the end of *do-loop*.

TEAMS DISTRIBUTE PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: *Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the primary threads of the teams region, which will be executed concurrently using SIMD instructions.*

Syntax

```
!$OMP TEAMS DISTRIBUTE PARALLEL DO SIMD [clause[[,] clause]... ]
   do-loop
[!$OMP END TEAMS DISTRIBUTE PARALLEL DO SIMD]
```

clause — Can be any of the clauses accepted by the TEAMS or DISTRIBUTE PARALLEL DO SIMD directives with identical meanings and restrictions.

do-loop — Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TEAMS construct immediately followed by a DISTRIBUTE PARALLEL DO SIMD construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately.

If the END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END TEAMS DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of do-loop.

OpenMP Fortran Compiler Directives

Syntax Rules for Compiler Directives

TEAMS LOOP

OpenMP* Fortran Compiler Directive: *Specifies a shortcut for specifying a LOOP construct inside a TEAMS construct. This feature is only available for ifx.*

Syntax

```
!$OMP TEAMS LOOP [clause[[,] clause]... ]
   do-loop
[!$OMP END TEAMS LOOP]
```

clause	Can be any of the clauses accepted by the TEAMS or LOOP directives with identical meanings and restrictions.
do-loop	Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer. The loop can be a DO CONCURRENT loop, subject to the rules specified for variables referenced in a DO CONCURRENT loop associated with LOOP and TEAMS constructs.

This combined directive is semantically equivalent to a LOOP construct that immediately follows a TEAMS directive. All restrictions for TEAMS and LOOP constructs apply to this combined construct.

If used, the END TEAMS LOOP directive must appear immediately after the end of the loop. If you do not specify an END TEAMS LOOP directive, an END TEAMS LOOP directive is assumed at the end of the *do-loop*.

LOOP directive

THIS_IMAGE

Transformational Intrinsic Function (Generic): *Returns the image index of the invoking image on the current or specified team, or the cosubscripts for the executing image on the current or specified team.*

Syntax

```
result = THIS_IMAGE ([ team ])
result = THIS_IMAGE (coarray [, team])
result = THIS_IMAGE (coarray, dim [, team])
```

team	(Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value describes the current team or an ancestor team. If *team* is not specified, the team is the current team.
coarray	(Input; optional) Must be a coarray; it can be of any type. If it is allocatable, it must be allocated. If *team* is specified, *coarray* must be established on that team.

dim	(Input; optional) Must be a scalar of type integer. *coarray* must be specified if *dim* is present. Its value must be in the range 1 <= *dim* <= *n*, where *n* is the corank of *coarray*. If the corresponding actual argument is an optional dummy argument, it must be present.

Results

The result type is default integer. It is scalar if *coarray* is not specified or *dim* is specified; otherwise, the result has rank one and its size is equal to the corank of *coarray*.

The result depends on which arguments are specified:

- If no argument is specified, as in THIS_IMAGE ( ), the result is a scalar with a value equal to the index of the invoking image on the current team.
- If only the team argument is specified, the result is a scalar with a value equal to the index of the invoking image on the specified team.
- If *coarray* is specified and *dim* is not, the result is the sequence of cosubscript values for *coarray* that would specify the invoking image on the specified team, or the current team if *team* is not specified.
- If *coarray* and *dim* are specified, the result is the value of cosubscript *dim* in the sequence of cosubscript values for *coarray* that would specify the invoking image on the specified team, or the current team if *team* is not specified.

Examples

Consider that coarray C is declared by the following statement:

```
REAL C(5, 10) [10, 0:9, 0:*]
```

On image 5 of the current team, THIS_IMAGE ( ) has the value 5 and THIS IMAGE (C) has the value [5, 0, 0]. For the same coarray on image 213, THIS_IMAGE (C) has the value [3, 1, 2].

In the following example, image 1 on the current team is used to read data. The other images then copy the data:

```
IF (THIS_IMAGE()==1) READ (*,*) P
SYNC ALL
P = P[1]
```

Consider the following program:

```
  PROGRAM main
  USE, INTRINSIC       :: ISO_FORTRAN_ENV
  TYPE (TEAM_TYPE)     :: initial, odd_even
  INTEGER coarray1[0:9, 10, *], coarray2 [10, 10, *]
  initial = GET_TEAM (CURRENT_TEAM)
  FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
  PRINT *, THIS_IMAGE()
  PRINT *, THIS_IMAGE (coarray1)
  PRINT *, THIS_IMAGE (coarray2, 2)
  CHANGE TEAM (odd_even)
    . . .
    PRINT *, THIS_IMAGE(), THIS_IMAGE(initial)
    PRINT *, THIS_IMAGE(coarray1)
    PRINT *, THIS_IMAGE(coarry2,TEAM = initial)
    PRINT *, THIS_IMAGE(coarray2, 2)
    PRINT *, THIS_IMAGE(coarray2, 2, initial)
    . . .
  END TEAM
  . . .
  END PROGRAM
```

If there are 1024 images on the initial team, on image 8 of the initial team, the first print statement will print 8, the second print statement will print the value of the array [7, 1, 1], and the third print statement will print 1. On that same image, the first print statement inside the CHANGE TEAM construct prints 4, 8, the second prints the value of the array [7, 1, 1], the third prints the value of the array [8, 1, 1], and the fourth and fifth both print 1.

On image 512 of the original team, the first print statement will print 512, the second print statement will print the value of the array [1, 2, 6], and the third will print 2. On the same image inside the CHANGE team construct, the first print statement will print 256 and 512, the second prints the value of the array [1,2,6], the third prints the value of the array [2,2,6], and the fourth and fifth both print 2.

THREAD_LIMIT

Parallel Directive Clause: *Specifies the maximum number of threads that can participate in a construct. This feature is only available for ifx.*

Syntax

`THREAD_LIMIT (`*`scalar-integer-expression`*`)`

`scalar-integer-expression`	Is an integer expression. It must evaluate to a positive scalar integer value.

At most one THREAD_LIMIT clause can appear in a directive that allows the clause.

If THREAD_LIMIT is not specified, the default thread limit is determined by the internal control variable (ICV) named `thread_limit`.

THREADPRIVATE

OpenMP* Fortran Compiler Directive: *Specifies named common blocks and certain variables to be private (local) to each thread; they are global within the thread.*

Syntax

`!$OMP THREADPRIVATE (`*`list`*`)`

`list`	Is a comma-separated list of named common blocks, module variables, or variables that have the SAVE attribute. These objects are made private to a thread. Note that common blocks must appear between slashes (/). A blank common block cannot appear in a THREADPRIVATE directive. A variable that appears in a THREADPRIVATE directive must be declared in the scope of a module or have the SAVE attribute, either explicitly or implicitly.

Each thread gets its own copy of the common block or variable, so data written to this object by one thread is not directly visible to other threads.

During serial portions and MASKED sections of the program, accesses are to the primary thread copy of the common block or variable. On entry to the first parallel region, data in the THREADPRIVATE common blocks or variables should be assumed to be undefined unless a COPYIN clause is specified in the PARALLEL directive.

The THREADPRIVATE directive must appear in the section of a scoping unit in which the common block or variable is declared. Although variables in common blocks can be accessed by use association or host association, common block names cannot. This means that a common block name specified in a THREADPRIVATE directive must be declared to be a common block in the same scoping unit in which the THREADPRIVATE directive appears.

When a common block (which is initialized using DATA statements) appears in a THREADPRIVATE directive, each thread copy is initialized once prior to its first use. For subsequent parallel regions, data in THREADPRIVATE common blocks are guaranteed to persist only if the dynamic threads mechanism has been disabled and if the number of threads are the same for all the parallel regions.

A THREADPRIVATE common block or its constituent variables can appear only in a COPYIN clause. They are not permitted in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, SHARED, or REDUCTION clause. They are not affected by the DEFAULT clause.

If a THREADPRIVATE directive specifying a common block name appears in one program unit, then the directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. It must appear after the last COMMON statement in the program unit.

If a THREADPRIVATE variable or a THREADPRIVATE common block is declared with the BIND attribute, the corresponding C entities must also be specified in a threadprivate directive in the C program.

The following are other restrictions for a THREADPRIVATE variable:

- The variable must not appear in any clause except the COPYIN, COPYPRIVATE, SCHEDULE, NUM_THREADS, THREAD_LIMIT, and IF clauses.
- It is affected by a COPYIN clause if the variable appears in the COPYIN clause or it is in a common block that appears in the COPYIN clause.
- It must not be an element of a common block or appear in an EQUIVALENCE statement.
- If it is part of another variable (as an array or structure element), it cannot appear in a THREADPRIVATE directive clause.
- Referencing a THREADPRIVATE variable in a DO CONCURRENT loop has undefined behavior.

NOTE
On Windows* systems, if you specify option `/Qopenmp-threadprivate:compat`, the compiler does not generate threadsafe code for common blocks in an !$OMP THREADPRIVATE directive unless at least one element in the common block is explicitly initialized.

Example

In the following example, the common blocks BLK1 and FIELDS are specified as thread private:

```
      COMMON /BLK/ SCRATCH
      COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
!$OMP THREADPRIVATE(/BLK/,/FIELDS/)
!$OMP PARALLEL DEFAULT(PRIVATE) COPYIN(/BLK1/,ZFIELD)
```

Syntax Rules for Compiler Directives

TILE

OpenMP* Fortran Compiler Directive: *Tiles (or blocks) one or more loops of a loop nest. This feature is only available for ifx.*

Syntax

```
!$OMP TILE clause
```

loop-nest

[!$OMP END TILE]

clause

Is SIZES (*size-list*)

The clause is required, and it can appear only once.

The *size-list* is a list of positive integer expressions (s1, … s*n*), where *n* is less than or equal to the number of loops in the *loop-nest*.

When *n* is the number of integer expressions in *size-list*, the depth of the loop nest must be at least *n*. The TILE construct replaces the outer *n* loops with 2*n* perfectly nested loops.

The outer *n* loops are called the floor loops, f_1, … f_n, from outermost to innermost floor loop.

The inner *n* loops, nested within floor loop f_n, are the tile loops, t_1, … t_n, from outermost to innermost tile loop. The resulting tile loops do not have canonical form.

The value of the expression s_i specifies the maximum iteration value for the tile loop t_i.

A tile loop that contains s_k iterations, where s_k is the kth expression in *size-list*, is a complete tile; otherwise, it is a partial tile loop.

loop-nest

Is a nest of DO loops in canonical form.

Description

TILE is a pure directive, so it can appear in a Fortran PURE procedure.

Loop tiling, also known as loop blocking, is a loop transformation performed on loops within loop nests. The transformation splits the processing of data into smaller segments called tiles (or blocks), which allows the data in the tiles (or blocks) to be accessed in parallel.

The loops associated with the construct must be perfectly nested. Each loop associated with the construct must be rectangular, that is, the loop control expressions of an inner loop cannot depend on the loop control variable of an outer loop.

Tiled loops perform best when a loop's iteration count is a multiple of the tile size for that loop. When the iteration count is not a multiple of the tile size, the loop nest may be transformed in a number of different ways. This allows partial tiles to execute in a manner that is optimal for the target hardware. The specified order of iterations must be preserved in the complete tile loops.

TILE constructs can be nested. If two TILE constructs are nested, the result is as if the outer TILE construct is applied to the resulting transformed loop nest created by the inner TILE construct.

Examples

In the following example, the loop iteration counts are each a multiple of their corresponding tile size, so there are no resulting partial tile loops. The PARALLEL DO construct is applied to the transformed loop nest.

The inner loop iterates through the rows, and the outer loop iterates through the columns, of a 64 x 20 matrix. The size expressions 8 and 4 specified in the SIZES clause of the TILE construct indicate a 8 x 4 blocking applied to the outer and inner loops:

```
INTEGER,DIMENSION (64,20) :: arr
INTEGER                   :: i, j
!$OMP PARALLEL DO
!$OMP TILE SIZES(8,4)
DO i = 1, 64
```

```
    DO j = 1, 20
      arr(i,j) = arr(i,j)*10
    END DO
  END DO
```

The transformed tiled loops are the following:

```
INTEGER,DIMENSION (64,20) :: arr
INTEGER                   :: i_inner, i_outer, j_inner, j_outer
!$OMP PARALLEL DO
DO i_outer = 1, 64, 8
  DO j_outer = 1, 20, 4
    DO i_inner = i_outer, i_outer+(8-1)
      DO j_inner = j_outer, j_outer+(4-1)
        arr(i_inner,j_inner) = arr(i_inner,j_inner)*10
      END DO
    END DO
  END DO
END DO
```

In the following example, the inner loop iteration count 20 is not a multiple of the corresponding tile size 7. To handle the remaining iterations, there may be a partial tile loop depending on how the loop is transformed:

```
  INTEGER,DIMENSION (64,20) :: arr
  INTEGER                   :: i, j
  !$OMP TILE SIZES(8,7)
  DO i = 1, 64
    DO j = 1, 20
      arr(i,j) = arr(i,j) * 10
    END DO
  END DO
```

In this case, various transformations are possible. The compiler is free to pick a transformation that is optimal for the target hardware. The order of execution of one tile with respect to other tiles can be changed, but within a given tile, the order of iteration execution must be preserved.

One possible transformation for the above loop nest is the following:

```
INTEGER,DIMENSION (64,20) :: arr
INTEGER                   :: i_inner, i_outer, j_inner, j_outer, j
! Complete tiles
DO i_outer = 1, 64, 8
  DO j_outer = 1, 14, 7
    DO i_inner = i_outer, i_outer + (8-1)
      DO j_inner = j_outer, j_outer + (7-1)
        arr(i_inner,j_inner) = arr(i_inner,j_inner)*10
      END DO
    END DO
  END DO
END DO

! Partial tiles
DO i_outer = 1, 64, 8
  DO i_inner = i_outer, i_outer + (8-1)
    DO j = 15, 20
      arr(i_inner,j) = arr(i_inner,j) * 10
    END DO
  END DO
END DO
```

An equivalent transformation for the tiled loop nest is the following:

```
INTEGER,DIMENSION (64,20) :: arr
INTEGER                   :: i_inner, i_outer, j_inner, j_outer
DO i_outer = 1, 64, 8
  DO j_outer = 1, 20, 7
    DO i_inner = i_outer, i_outer + (8-1)
      DO j_inner = j_outer, MIN(j_outer+(7-1),20)
        arr(i_inner,j_inner) = arr(i_inner,j_inner) * 10
      END DO
    END DO
  END DO
END DO
```

TIME Intrinsic Procedure

Intrinsic Subroutine (Generic): *Returns the current time as set within the system. TIME can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.*

Syntax

`CALL TIME (buf)`

buf	(Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least eight bytes of storage.

The date is returned as a 8-byte ASCII character string taking the form hh:mm:ss, where:

hh	is the 2-digit hour
mm	is the 2-digit minute
ss	is the 2-digit second

If *buf* is of numeric type and smaller than 8 bytes, data corruption can occur.

If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 8 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

Example

```
CHARACTER*1 HOUR(8)
...
CALL TIME (HOUR)
```

The length of the first array element in CHARACTER array HOUR is passed to the TIME subroutine. The subroutine then truncates the time to fit into the 1-character element, producing an incorrect result.

DATE_AND_TIME

TIME portability routine

TIME Portability Routine

Portability Function or Subroutine: *The function returns the system time, in seconds, since 00:00:00 Greenwich mean time, January 1, 1970. TIME can be used as a portability function or subroutine, or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.*

Module

USE IFPORT

Syntax

Function Syntax:

```
result = TIME( )
```

Subroutine Syntax:

```
CALL TIME (timestr)
```

timestr	(Output) Character*(*). Is the current time, based on a 24-hour clock, in the form hh:mm:ss, where hh, mm, and ss are two-digit representations of the current hour, minutes past the hour, and seconds past the minute, respectively.

Results

The result type is INTEGER(4). The result value is the number of seconds that have elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

The subroutine fills a parameter with the current time as a string in the format hh:mm:ss.

The value returned by this routine can be used as input to other portability date and time functions.

Example

```
USE IFPORT
INTEGER(4) int_time
character*8 char_time
int_time = TIME( )
call TIME(char_time)
print *, 'Integer: ', int_time, 'time: ', char_time
END
```

See Also

DATE_AND_TIME

TIME intrinsic procedure

TIMEF

Portability Function: *Returns the number of seconds since the first time it is called, or zero.*

Module

USE IFPORT

Syntax

```
result = TIMEF( )
```

Results

The result type is REAL(8). The result value is the number of seconds that have elapsed since the first time TIMEF was called.

The first time it is called, TIMEF returns 0.

Example

```
USE IFPORT
INTEGER i, j
REAL(8) elapsed_time
elapsed_time = TIMEF( )
DO i = 1, 100000
   j = j + 1
END DO
elapsed_time = TIMEF( )
PRINT *, elapsed_time
END
```

Date and Time Procedures

TINY

Inquiry Intrinsic Function (Generic): *Returns the smallest number in the model representing the same type and kind parameters as the argument.*

Syntax

```
result = TINY (x)
```

x	(Input) Must be of type real; it can be scalar or array valued.

Results

The result is a scalar with the same type and kind parameters as *x*. The result has the value b $^{e_{min}}$ - 1. Parameters *b* and e_{min} are defined in Model for Real Data.

Example

If X is of type REAL(4), TINY (X) has the value 2 $^{-126}$.

The following shows another example:

```
REAL(8) r, result
r = 487923.3D0
result = TINY(r)    ! returns 2.225073858507201E-308
```

Data Representation Models

TRACEBACKQQ

Runtime Subroutine: *Provides traceback information. Uses the Intel® Fortran runtime library traceback facility to generate a stack trace showing the program call stack as it appeared at the time of the call to TRACEBACKQQ( ).*

Module

USE IFCORE

Syntax

`CALL TRACEBACKQQ ([string] [,user_exit_code] [,status] [,eptr])`

string

(Input; optional) CHARACTER*(*). A message string to precede the traceback output. It is recommended that the string be no more than 80 characters (one line) since that length appears better on output. However, this limit is not a restriction and it is not enforced. The string is output exactly as specified; no formatting or interpretation is done.

If this argument is omitted, no header message string is produced.

user_exit_code

(Input; optional) INTEGER(4). An exit code. Two values are predefined:

- A value of -1 causes the runtime system to return execution to the caller after producing traceback.
- A value of zero (the default) causes the application to abort execution.

Any other specified value causes the application to abort execution and return the specified value to the operating system.

status

(Input; optional) INTEGER(4). A status value. If specified, the runtime system returns the status value to the caller indicating that the traceback process was successful. The default is not to return status.

Note that a returned status value is only an indication that the "attempt" to trace the call stack was completed successfully, not that it produced a useful result.

You can include the file `iosdef.for`in your program to obtain symbolic definitions for the possible return values. A return value of FOR$IOS_SUCCESS (0) indicates success.

eptr

(Input; optional) Integer pointer. It is required if calling from a user-specified exception filter. If omitted, the default in null.

To trace the stack after an exception has occurred, the runtime support needs access to the exception information supplied to the filter by the operating system.

The *eptr* argument is a pointer to a T_EXCEPTION_POINTERS structure, which is defined in `ifcore.f90`. This argument is optional and is usually omitted. On Windows* systems, T_EXCEPTION_POINTERS is returned by the Windows* API GetExceptionInformation( ), which is usually passed to a C try/except filter function.

The TRACEBACKQQ routine provides a standard way for an application to initiate a stack trace. It can be used to report application detected errors, debugging, and so forth. It uses the stack trace support in the Intel Fortran runtime library, and produces the same output that the runtime library produces for unhandled errors and exceptions.

The error message string normally included by the runtime system is replaced with the user-supplied message text, or omitted if no string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the runtime system.

Example

In the most simple case, you can generate a stack trace by coding the call to TRACEBACKQQ with no arguments:

```
CALL TRACEBACKQQ()
```

This call causes the runtime library to generate a traceback report with no leading header message, from wherever the call site is, and terminate execution.

The following example generates a traceback report with no leading header message, from wherever the call site is, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ( )
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution:

```
USE IFCORE
CALL TRACEBACKQQ("My application message string")
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution, returning a status code of 123 to the operating system:

```
USE IFCORE
CALL TRACEBACKQQ(STRING="Bad value for TEMP",USER_EXIT_CODE=123)
```

Consider the following:

```
...
USE IFCORE
INTEGER(4) RTN_STS
INCLUDE 'IOSDEF.FOR'
...
CALL TRACEBACKQQ(USER_EXIT_CODE=-1,STATUS=RTN_STS)
IF (RTN_STS .EQ. FOR$IOS_SUCCESS) THEN
  PRINT *,'TRACEBACK WAS SUCCESSFUL'
END IF
...
```

This example generates a traceback report with no header string, and returns to the caller to continue execution of the application. If the traceback process succeeds, a status will be returned in variable RTN_STS.

You can specify arguments that generate a stack trace with the user-supplied string as the header and instead of terminating execution, return control to the caller to continue execution of the application. For example:

```
CALL TRACEBACKQQ(STRING="Done with pass 1",USER_EXIT_CODE=-1)
```

By specifying a user exit code of -1, control returns to the calling program. Specifying a user exit code with a positive value requests that specified value be returned to the operating system. The default value is 0, which causes the application to abort execution.

Windows* Example:

The following example demonstrates the use of the EPTR argument when calling from a user-defined exception filter function. The premise of the example is a Fortran DLL containing entry points protected by a C `try/except` construct, such as:

```
__declspec(dllexport) void FPE_TEST_WRAPPER ()
{
__try {
     /*
     **  call the Fortran code...
     */
     FPE_TEST() ;
     }
__except ( CHECK_EXCEPTION_INFO ( GetExceptionInformation() ) )
     {
     /*
     **  noncontinuable exception handling here, if any.
     */
     }
```

The C function shown above is guarding against a floating-point divide-by-zero exception. This function calls the user-supplied FPE_TEST (not shown). The Fortran function CHECK_EXCEPTION_INFO shown below (called in the __except filter expression above) can use TRACEBACKQQ to get a stack trace as follows:

```
  INTEGER*4 FUNCTION CHECK_EXCEPTION_INFO ( ExceptionInfo )
  !DIR$ ATTRIBUTES DLLEXPORT::CHECK_EXCEPTION_INFO
  USE IFWINTY
  !DIR$ ATTRIBUTES REFERENCE :: ExceptionInfo
  TYPE(T_EXCEPTION_POINTERS) ExceptionInfo
  TYPE(T_EXCEPTION_RECORD) erecptr
  TYPE(T_CONTEXT) ctxptr
  POINTER(eptr,erecptr)
  POINTER(ctxp,ctxptr)
  INTEGER(4) EXIT_CODE,STS
  CHARACTER(LEN=70) MYSTR
! Init the arguments to TRACEBACKQQ appropriately for your needs...
  EXIT_CODE=-1
  eptr = ExceptionInfo.ExceptionRecord
  ctxp = ExceptionInfo.ContextRecord
  IF ( erecptr.ExceptionCode .EQ. STATUS_FLOAT_DIVIDE_BY_ZERO ) THEN
         PRINT *, 'Saw floating divide by zero.'
         PRINT '(1x,a,z8.8)', 'ContextRecord.FloatSave.StatusWord = ', &
                 ctxptr.FloatSave.StatusWord
         MYSTR = "FLTDIV EXCEPTION IN MY APPLICATION"
         CALL TRACEBACKQQ(MYSTR,EXIT_CODE,STS, %LOC(ExceptionInfo))
  END IF
  .
  .
  .
  CHECK_EXCEPTION_INFO = 1
  END
```

To return a pointer to C runtime exception information pointers within a user-defined handler that was established with SIGNALQQ (or directly with the C signal function), you can call the GETEXCEPTIONPTRSQQ routine.

See Also

GETEXCEPTIONPTRSQQ

TRAILZ

Elemental Intrinsic Function (Specific): *Returns the number of trailing zero bits in an integer.*

Syntax

```
result = TRAILZ (i)
```

i	(Input) Must be of type integer or logical.

Results

The result type is default integer. The result value is the number of trailing zeros in the binary representation of the integer *i*.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

Consider the following:

```
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
  TYPE *, TRAILZ(TWO**J)  ! Prints 64, then 0 up to
ENDDO                     !   40 (trailing zeros)
END
```

TRANSFER

Transformational Intrinsic Function (Generic): *Converts the bit pattern of the first argument according to the type and kind parameters of the second argument.*

Syntax

```
result = TRANSFER (source,mold[,size])
```

source	(Input) Must be a scalar or array (of any data type).
mold	(Input) Must be a scalar or array (of any data type). It provides the type characteristics (not a value) for the result.
size	(Input; optional) Must be scalar and of type integer. It provides the number of elements for the output result.

Results

The result has the same type and type parameters as *mold*.

If *mold* is a scalar and *size* is omitted, the result is a scalar.

If *mold* is an array and *size* is omitted, the result is a rank-one array. Its size is the smallest that is possible to hold all of *source*.

If *size* is present, the result is a rank-one array of size *size*.

When the size of *source* is greater than zero, *mold* must not be an array with elements of size zero.

If the internal representation of the result occupies m bits, and the internal representation of *source* occupies n bits, then if m > n, the right-most src bits of result contain the bit pattern contained in *source*, and the m minus n left-most bits of result are undefined. If m < n, then result contains the bit pattern of the right-most m bits of *source*, and the left-most n minus m bits of *source* are ignored. Otherwise, the result contains the bit pattern contained in *source*.

Example

TRANSFER (1082130432, 0.0) has the value 4.0 (on processors that represent the values 4.0 and 1082130432 as the string of binary digits 0100 0000 1000 0000 0000 0000 0000 0000).

TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0))) results in a scalar whose value is (2.2, 3.3).

TRANSFER ((/2.2, 3.3, 4.4/), (/(0.0, 0.0)/)) results in a complex rank-one array of length 2. Its first element is (2.2,3.3) and its second element has a real part with the value 4.4 and an undefined imaginary part.

TRANSFER ((/2.2, 3.3, 4.4/), (/(0.0, 0.0)/), 1) results in a complex rank-one array having one element with the value (2.2, 3.3).

The following shows another example:

```
COMPLEX CVECTOR(2), CX(1)
!  The next statement sets CVECTOR to
!  [ 1.1 + 2.2i, 3.3 + 0.0i ]
CVECTOR = TRANSFER((/1.1, 2.2, 3.3, 0.0/), &
                   (/(0.0, 0.0)/))
!  The next statement sets CX to [ 1.1 + 2.2i ]
CX = TRANSFER((/1.1, 2.2, 3.3/) , (/(0.0, 0.0)/), &
              SIZE= 1)
WRITE(*,*) CVECTOR
WRITE(*,*) CX
END
```

The following example shows an error because the *source* size is greater than zero but *mold* is an array whose elements have zero size:

```
CHARACTER(0),PARAMETER :: nothing1(100) = ''
PRINT *,SIZE(TRANSFER(111014,nothing1))         ! error
...
```

TRANSPOSE

Transformational Intrinsic Function (Generic):
Transposes an array of rank two.

Syntax

`result = TRANSPOSE (`*matrix*`)`

matrix	(Input) Must be a rank-two array. It may be of any data type.

Results

The result is a rank-two array with the same type and kind parameters as *matrix*. Its shape is (n, m), where (m, n) is the shape of *matrix*. For example, if the shape of *matrix* is (4,6), the shape of the result is (6,4).

Element (i, j) of the result has the value *matrix*(j, i), where *i* is in the range 1 to n, and *j* is in the range 1 to m.

Example

B is the array

```
 [ 2  3  4 ]
 [ 5  6  7 ]
 [ 8  9  1 ].
```

TRANSPOSE (B) has the value

```
 [ 2  5  8 ]
 [ 3  6  9 ]
 [ 4  7  1 ].
```

The following shows another example:

```
INTEGER array(2, 3), result(3, 2)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is  1  3  5
!           2  4  6
result = TRANSPOSE(array)
! result is 1  2
!           3  4
!           5  6
END
```

See Also

RESHAPE
PRODUCT

TRIM

Transformational Intrinsic Function (Generic):
Returns the argument with trailing blanks removed.

Syntax

`result = TRIM (string)`

string	(Input) Must be a scalar of type character.

Results

The result is of type character with the same kind parameter as *string*. Its length is the length of *string* minus the number of trailing blanks in *string*.

The value of the result is the same as *string*, except any trailing blanks are removed. If *string* contains only blank characters, the result has zero length.

Example

TRIM (' NAME ') has the value ' NAME'.

TRIM (' C D ') has the value ' C D'.

The following shows another example:

```
! next line prints 30
WRITE(*, *) LEN("I have blanks behind me       ")
! the next line prints 23
WRITE(*,*) LEN(TRIM("I have blanks behind me       "))
END
```

See Also

LEN_TRIM

TTYNAM

Portability Subroutine: *Specifies a terminal device name.*

Module

USE IFPORT

Syntax

```
CALL TTYNAM (string,lunit)
```

string	(Output) Character*(*). Name of the terminal device. If the Fortran logical unit is not connected to a terminal, it returns a string filled with blanks.
lunit	(Input) INTEGER(4). A Fortran logical unit number.

Type Declarations

Statement: *Explicitly specifies the properties of data objects or functions.*

Syntax

A type declaration has the general form:

```
type-spec[ [, att] ... :: ] v[/c-list/][, v[/c-list/]] ...
```

type-spec	Is one of the following: *intrin-type* TYPE (*intrin-type*) TYPE (derived-type-name) For information about parameterized derived types, see Parameterized Derived-Type Declarations. TYPE (*) This defines the entity as an assumed-type object. CLASS (derived-type-name) CLASS (*)
intrin-type	Is one of the following data type specifiers: BYTE INTEGER[([KIND=]k)] REAL[([KIND=]k)] DOUBLE PRECISION COMPLEX[([KIND=]k)] DOUBLE COMPLEX CHARACTER[([KIND=]k)] LOGICAL[([KIND=]k)]

In the optional kind selector "([KIND=]k)", *k* is the kind parameter. It must be an acceptable kind parameter for that data type. If the kind selector is not present, entities declared are of default type.

When *type-spec* is *intrin-type*, kind parameters for intrinsic numeric and logical data types can also be specified using the *n format, where *n* is the length (in bytes) of the entity; for example, INTEGER*4. The *n format cannot be used when *type-spec* is TYPE (*intrin-type*).

See each data type for further information on that type.

att

Is one of the following attribute specifiers:

ALLOCATABLE	EXTERNAL	PROTECTED
ASYNCHRONOUS	INTENT	PUBLIC[1]
AUTOMATIC	INTRINSIC	SAVE
BIND	OPTIONAL	STATIC
CODIMENSION	PARAMETER	TARGET
CONTIGUOUS	POINTER	VALUE
DIMENSION	PRIVATE[1]	VOLATILE

[1]These are access specifiers.

You can also declare any attribute separately as a statement.

v

Is the name of a data object or function. It can optionally be followed by:

- An array specification, if the object is an array.

  In a function declaration, an array must be a deferred-shape array if it has the POINTER or ALLOCATABLE attribute; otherwise, it must be an explicit-shape array.
- A coarray specification, if the object is a coarray
- A character length, if the object is of type character.
- A constant expression preceded by = or by one of the following for pointer objects:
  - => NULL( )
  - => target (pointer initialization)
- A codimension

A function name must be the name of an intrinsic function, external function, function dummy procedure, or statement function.

c-list

Is a list of constants, as in a DATA statement. If *v* has the PARAMETER attribute, the *c-list* cannot be present.

The *c-list* cannot specify more than one value unless it initializes an array. When initializing an array, the *c-list* must contain a value for every element in the array.

Description

Type declaration statements must precede all executable statements.

In most cases, a type declaration statement overrides (or confirms) the implicit type of an entity. However, a variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

The double colon separator (::) is required only if the declaration contains an attribute specifier or initialization; otherwise it is optional.

If *att* or a double colon (::) appears, *c-list* cannot be specified; for example:

```
INTEGER I /2/              ! Valid
INTEGER, SAVE :: I /2/     ! Invalid
INTEGER, SAVE :: I = 2     ! Valid
```

The same attribute must not appear more than once in a given type declaration statement, and an entity cannot be given the same attribute more than once in a scoping unit.

If CLASS is specified, the entity must be a dummy argument or have the ALLOCATABLE or POINTER attribute.

If the PARAMETER attribute is specified, the declaration must contain an constant expression. The PARAMETER attribute must not be specified for a dummy argument, a pointer, an allocatable entity, a function, or an object in a common block.

If => NULL( ) is specified for a pointer, its initial association status is disassociated.

If => target is specified for a pointer, the following rules apply:

- The pointer must be type compatible with the target.
- The pointer and target must have the same rank.
- All nondeferred type parameters of the pointer must have the same values as the corresponding type parameters of the target.
- If the pointer has the CONTIGUOUS attribute, the target must be contiguous.

A variable (or variable subobject) can only be initialized once in an executable program. If the variable is an array, it must have its shape specified in either the type declaration statement or a previous attribute specification statement in the same scoping unit.

The INTENT, VALUE, and OPTIONAL attributes can be specified only for dummy arguments.

The INTENT attribute must not be specified for a dummy procedure without the POINTER attribute.

If the VALUE attribute is specified, the length type parameter values must be omitted or specified by constant expressions. The VALUE attribute must not be specified for a dummy procedure.

An entity must not have both the EXTERNAL attribute and the INTRINSIC attribute. It can only have one of these attributes if it is a function.

The BIND attribute and the PROTECTED attribute can appear only in the specification part of a module.

A function result can be declared to have the POINTER or ALLOCATABLE attribute.

An automatic object cannot appear in a SAVE or DATA statement and it cannot be declared with a SAVE attribute nor be initially defined by an initialization.

The SAVE attribute must not be specified for:

- An object that is in a common block
- A procedure
- A dummy argument
- An automatic data object
- A function result
- An object with the PARAMETER attribute

The PROTECTED attribute is only allowed for a procedure pointer or named variable that is not in a common block. A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as:

- A pointer object in a NULLIFY statement
- A data pointer object or procedure pointer object in a pointer assignment statement
- An allocate object in an ALLOCATE statement or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following objects cannot be initialized in a type declaration:

- A dummy argument
- A function result
- An object in a named common block (unless the type declaration is in a block data program unit)
- An object in blank common
- An allocatable variable
- An external name
- An intrinsic name
- An automatic object
- An object that has the AUTOMATIC attribute

If a declaration contains a constant expression, but no PARAMETER attribute is specified, the object is a variable whose value is initially defined. The object becomes defined with the value determined from the constant expression according to the rules of intrinsic assignment.

When *type-spec* is *intrin-type*, the interpretation is exactly the same as it would have been without the keyword type and the parentheses. The following declarations for integers K and L and complexes A and B have identical results:

TYPE (INTEGER) :: K, L	INTEGER :: K, L
TYPE (COMPLEX (KIND (0.0D0))) :: A, B	COMPLEX (KIND (0.0D0)) :: A, B

A *derived-type-name* cannot be the same as the name of any standard intrinsic type. The type names BYTE and DOUBLECOMPLEX are not standard type names; they are Intel Fortran extensions. If BYTE or DOUBLECOMPLEX is declared to be a *derived-type-name*, it overrides the intrinsic name BYTE or DOUBLECOMPLEX. For example:

```
TYPE (DOUBLECOMPLEX) :: X     ! if DOUBLEXCOMPLEX is a defined-type
                              !    name, X is of that defined type
BYTE :: Y                     ! if BYTE is not a defined-type name,
                              !    Y is of intrinsic type BYTE, which
                              !    is the same as INTEGER(KIND=1)
```

The presence of initialization gives the object the SAVE attribute, except for objects in named common blocks or objects with the PARAMETER attribute.

When the entity is an assumed-type object, the following rules apply:

- The entity has no declared type and its dynamic type and type parameters are assumed from its effective argument. An assumed-type object is unlimited polymorphic.
- An assumed-type object must be a dummy variable that does not have the ALLOCATABLE, CODIMENSION, INTENT(OUT), POINTER, or VALUE attribute and is not an explicit-shape array.
- An assumed-type object that is not assumed-shape and not assumed-rank is intended to be passed as the C address of the object. A TYPE(*) explicit-shape array is not permitted because there is insufficient information passed for an assumed-type explicit-shape array that is an actual argument corresponding to an assumed-shape dummy argument to compute element offsets.

- An assumed-type variable name must not appear in a designator or expression except as an actual argument corresponding to a dummy argument that is assumed-type, or as the first argument to any of the following intrinsic or intrinsic module functions: IS_CONTIGUOUS, LBOUND, PRESENT, RANK, SHAPE, SIZE, UBOUND, and C_LOC.
- An assumed-type actual argument that corresponds to an assumed-rank dummy argument must be assumed-shape or assumed-rank.

An object can have more than one attribute. The following table lists the compatible attributes:

Compatible Attributes

Attribute	Compatible with:
ALLOCATABLE	AUTOMATIC, ASYNCHRONOUS, CODIMENSION, DIMENSION [1], PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC, TARGET, VOLATILE
ASYNCHRONOUS	ALLOCATABLE, AUTOMATIC, BIND, DIMENSION, INTENT, OPTIONAL, POINTER, PROTECTED, PUBLIC, SAVE, STATIC, TARGET, VALUE, VOLATILE
AUTOMATIC	ALLOCATABLE, ASYNCHRONOUS, BIND, DIMENSION, POINTER, PROTECTED, TARGET, VOLATILE
BIND	ASYNCHRONOUS, AUTOMATIC, DIMENSION, EXTERNAL, PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC, TARGET, VOLATILE
CODIMENSION	ALLOCATABLE, DIMENSION, INTENT, OPTIONAL, PRIVATE, PROTECTED, PUBLIC, SAVE, TARGET
CONTIGUOUS	DIMENSION, INTENT, OPTIONAL, POINTER, PRIVATE, PROTECTED, PUBLIC, TARGET
DIMENSION	ALLOCATABLE, ASYNCHRONOUS, AUTOMATIC, BIND, CODIMENSION, CONTIGUOUS, INTENT, OPTIONAL, PARAMETER, POINTER, PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC, TARGET, VOLATILE
EXTERNAL	BIND, OPTIONAL, PRIVATE, PUBLIC
INTENT	ASYNCHRONOUS, CODIMENSION, CONTIGUOUS, DIMENSION, OPTIONAL, TARGET, VOLATILE
INTRINSIC	PRIVATE, PUBLIC
OPTIONAL	ASYNCHRONOUS, CODIMENSION, CONTIGUOUS, DIMENSION, EXTERNAL, INTENT, POINTER, TARGET, VALUE, VOLATILE
PARAMETER	DIMENSION, PRIVATE, PUBLIC
POINTER	ASYNCHRONOUS, AUTOMATIC, CONTIGUOUS, DIMENSION [1], OPTIONAL, PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC, VOLATILE

Attribute	Compatible with:
PRIVATE	ASYNCHRONOUS, ALLOCATABLE, BIND, CODIMENSION, CONTIGUOUS, DIMENSION, EXTERNAL, INTRINSIC, PARAMETER, POINTER, PROTECTED, SAVE, STATIC, TARGET, VOLATILE
PROTECTED	ALLOCATABLE, ASYNCHRONOUS, BIND, CODIMENSION, CONTIGUOUS, DIMENSION, POINTER, PRIVATE, PUBLIC, SAVE, TARGET, VOLATILE
PUBLIC	ASYNCHRONOUS, ALLOCATABLE, BIND, CODIMENSION, CONTIGUOUS, DIMENSION, EXTERNAL, INTRINSIC, PARAMETER, POINTER, PROTECTED, SAVE, STATIC, TARGET, VOLATILE
SAVE	ALLOCATABLE, ASYNCHRONOUS, BIND, CODIMENSION, DIMENSION, POINTER, PRIVATE, PROTECTED, PUBLIC, STATIC, TARGET, VOLATILE
STATIC	ALLOCATABLE, ASYNCHRONOUS, BIND, DIMENSION, POINTER, PRIVATE, PROTECTED, PUBLIC, SAVE, TARGET, VOLATILE
TARGET	ALLOCATABLE, ASYNCHRONOUS, AUTOMATIC, BIND, CODIMENSION, CONTIGUOUS, DIMENSION, INTENT, OPTIONAL, PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC,VALUE, VOLATILE
VALUE	ASYNCHRONOUS, INTENT (IN only), OPTIONAL, TARGET
VOLATILE	ALLOCATABLE, ASYNCHRONOUS, AUTOMATIC, BIND, DIMENSION, INTENT, OPTIONAL, POINTER, PRIVATE, PROTECTED, PUBLIC, SAVE, STATIC, TARGET
[1]With deferred shape	

Example

The following show valid type declaration statements:

```
DOUBLE PRECISION B(6)
INTEGER(KIND=2) I
REAL(KIND=4) X, Y
REAL(4) X, Y
LOGICAL, DIMENSION(10,10) :: ARRAY_A, ARRAY_B
INTEGER, PARAMETER :: SMALLEST = SELECTED_REAL_KIND(6, 70)
REAL(KIND (0.0)) M
COMPLEX(KIND=8) :: D
TYPE(EMPLOYEE) :: MANAGER
REAL, INTRINSIC :: COS
CHARACTER(15) PROMPT
CHARACTER*12, SAVE :: HELLO_MSG
INTEGER COUNT, MATRIX(4,4), SUM
LOGICAL*2 SWITCH
```

```
REAL :: X = 2.0

TYPE (NUM), POINTER :: FIRST => NULL()
```

The following shows more examples:

```
REAL a (10)
LOGICAL, DIMENSION (5, 5) :: mask1, mask2
TYPE (COMPLEX) :: cube_root = (-0.5, 0.867)
INTEGER, PARAMETER :: short = SELECTED_INT_KIND (4)
REAL (KIND (0.0D0)) a1
TYPE (REAL (KIND = 4)) b
COMPLEX (KIND = KIND (0.0D0)) :: c
INTEGER (short) k ! Range at least -9999 to 9999
TYPE (member) :: george
```

The following shows an example of pointer initialization:

```
integer, target :: v (5) = [1, 2, 3, 4, 5]
type entry
  integer, pointer :: p (5) => v     ! pointer component default initialization
end type entry

type (entry), target :: bottom
type (entry), pointer :: top => bottom     ! pointer initialization
```

TYPE Statement for Derived Types

Statement: *Declares a variable to be of derived type. It specifies the name of the user-defined type and the types of its components.*

Syntax

```
TYPE [[,attr-list] :: ] name [(type-param-name-list)]
   [type-param-def-stmts]
   [PRIVATE statement or SEQUENCE statement]. . .
   [component-definition]. . .
   [type-bound-procedure-part]
END TYPE [name]
```

attr-list	Is one of the following: • *access-spec* Is the PUBLIC or PRIVATE attribute. The attribute can only be specified if the derived-type definition is in the specification part of a module. • BIND(C) • EXTENDS (*parent-type-name*) where *parent-type-name* is the name of a previously defined extensible type. • ABSTRACT The same *attr* must not appear more than once in any given derived-type statement. If the type definition contains or inherits a deferred binding, ABSTRACT must appear. The EXTENDS and ABSTRACT attributes apply to type extension and extended types. If ABSTRACT is specified, the type is an abstract type and it must be extensible. A derived type that does not have the SEQUENCE or BIND(C) attribute is extensible. Conversely, a derived type that has the SEQUENCE or BIND(C) attribute is not extensible.
name	Is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.
type-param-name-list	Is a list of type parameter names separated by commas. For more information, see Parameterized Derived-Type Declarations.
type-param-def-stmts	Is one or more INTEGER declarations of the type parameters named in the *type-param-name-list*. For more information, see Parameterized Derived-Type Declarations.
component-definition	Is one or more type declaration statements or procedure pointer statements defining the component of derived type. The first component definition can be preceded by an optional PRIVATE or SEQUENCE statement. (Only one PRIVATE and only one SEQUENCE statement can appear in a given derived-type definition.) If SEQUENCE is present, all derived types specified in component definitions must be sequence types. Procedure pointer component definitions are described in Procedure Pointers as Derived-Type Components. The syntax for a type declaration component definition is described below.
type-bound-procedure-part	Is a CONTAINS statement, optionally followed by a PRIVATE statement, and one or more procedure binding statements (specific, generic, or final). For more information, see Type-Bound Procedures.

A type declaration component definition takes the following form:

type[[, *attr*] ::] *component*[(*a-spec*)] [[*coarray-spec*]] [**char-len*] [*init-ex*]

type

Is a type specifier. It can be an intrinsic type or a previously defined derived type.

If the POINTER or the ALLOCATABLE attribute follows this specifier, the type can also be the type being defined or any accessible derived type, whether previously defined or not.

attr

Is at most one of the following:

- An optional POINTER attribute for a pointer component
- An optional ALLOCATABLE attribute for a scalar component
- An optional DIMENSION or ALLOCATABLE attribute for an array component

  You cannot specify both the ALLOCATABLE and POINTER attribute.
- An optional access specifier, PUBLIC or PRIVATE
- An optional CODIMENSION [coarray-spec] to specify a coarray
- An optional CONTIGUOUS attribute if the object is contiguous

Each attribute can only appear once in a given component definition.

If neither the POINTER nor the ALLOCATABLE attribute is specified, *type* must specify an intrinsic type or a previously defined derived type.

If neither the POINTER nor the ALLOCATABLE attribute is specified, each *a-spec* must be an explicit-shape specification.

If the POINTER or ALLOCATABLE attribute is specified, each component array specification *a-spec* must be a deferred shape specification (d-spec).

If a *coarray-spec* appears, it must be a deferred specification list consisting of one or more colons (:), the component must have the ALLOCATABLE attribute, and the component must not be of type C_PTR or C_FUNPTR from the intrinsic module ISO_C_BINDING or of type TEAM_TYPE from the intrinsic module ISO_FORTRAN_ENV.

A data component whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar and must not be a coarray.

If the CONTIGUOUS attribute is specified, the component must be an array with the POINTER attribute.

component

Is the name of the component being defined.

a-spec

Is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression.

If *component* is an array and the array bounds are not specified here, they must be specified following the DIMENSION attribute.

coarray-spec

Is a deferred-coshape specification. The left bracket and right bracket are required.

char-len

Is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.

init-ex

Is one of the following:

- = constant expression for nonpointer components
- => NULL( ) for pointer components

If *init-ex* is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components.

The constant expression is evaluated in the scoping unit of the type definition.

Description

If a name is specified following the END TYPE statement, it must be the same name that follows TYPE in the derived type statement.

A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.

The default accessibility attribute for a module is PUBLIC unless it has been changed by a PRIVATE statement with no entity-list.

A PUBLIC or PRIVATE keyword can only appear on the TYPE statement of a derived-type definition, or on a component or type-bound procedure declaration of the type if the derived-type definition is in the specification part of a module.

The PRIVATE statement can only be specified in the *component-definition* or *type-bound-procedure-part* if the derived-type definition is in the specification part of a module. A PRIVATE statement inside a *component-definition* part specifies that the default accessibility of all components of the derived type are PRIVATE. Similarly, a PRIVATE statement inside a *type-bound-procedure-part* specifies that the default accessibility of the type bound procedures of the derived type are PRIVATE. If the default accessibility of components or type-bound procedures is PRIVATE, individual components or type-bound procedures can be declared PUBLIC, overriding the default accessibility attribute.

If a type definition is PRIVATE, the type name and the structure constructor for the type are accessible only within the module containing the definition and in the descendants of that module.

Two data entities have the same type if they are both declared to be of the same derived type; the derived-type definition can be accessed from a module or a host scoping unit.

If EXTENDS appears and the type being defined has a coarray ultimate component, its parent type must have a coarray ultimate component.

Data entities in different scoping units also have the same type if the following is true:

- They are declared with reference to different derived-type definitions that specify the same type name.
- All have the SEQUENCE property.
- All have the BIND attribute.
- They have no components with PRIVATE accessibility.
- They have type parameters and components that agree in order, name, and attributes.

Otherwise, they are of different derived types.

A data component is a coarray if the component declaration contains a coarray specification. If the component declaration contains a coarray specification, it specifies the corank.

If BIND (C) is specified, the following rules apply:

- The derived type cannot be a SEQUENCE type.
- The derived type must not have type parameters.
- The derived type must not have the EXTENDS attribute.

- The derived type must not have a *type-bound-procedure-part*.
- Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.

Example

```
!   DERIVED.F90
!   Define a derived-type structure,
!   type variables, and assign values

    TYPE member
      INTEGER age
      CHARACTER (LEN = 20) name
    END TYPE member

    TYPE (member) :: george
    TYPE (member) :: ernie

    george     = member( 33, 'George Brown' )
    ernie%age  = 56
    ernie%name = 'Ernie Brown'

    WRITE (*,*) george
    WRITE (*,*) ernie
    END
```

The following shows another example of a derived type:

```
TYPE mem_name
  SEQUENCE
  CHARACTER (LEN = 20) lastn
  CHARACTER (LEN = 20) firstn
  CHARACTER (len = 3) cos   ! this works because COS is a component name
END TYPE mem_name
TYPE member
    SEQUENCE
    TYPE (mem_name) :: name
    INTEGER age
    CHARACTER (LEN = 20) specialty
END TYPE member
```

In the following example, `a` and `b` are both variable arrays of derived type `pair`:

```
USE, INTRINSIC :: ISO_C_BINDING
TYPE, BIND(C) :: pair
  INTEGER(C_INT) :: i, j
END TYPE
TYPE (pair) :: a, b(3)
```

The following example shows how you can use derived-type objects as components of other derived-type objects:

```
TYPE employee_name
  CHARACTER(25) last_name
  CHARACTER(15) first_name
END TYPE
TYPE employee_addr
  CHARACTER(20) street_name
  INTEGER(2) street_number
  INTEGER(2) apt_number
  CHARACTER(20) city
```

```
   CHARACTER(2) state
   INTEGER(4) zip
 END TYPE
```

Objects of these derived types can then be used within a third derived-type specification, such as:

```
 TYPE employee_data
   TYPE (employee_name) :: name
   TYPE (employee_addr) :: addr
   INTEGER(4) telephone
   INTEGER(2) date_of_birth
   INTEGER(2) date_of_hire
   INTEGER(2) social_security(3)
   LOGICAL(2) married
   INTEGER(2) dependents
 END TYPE
```

The following program shows how you initialize components of a derived-type object:

```
TYPE list_node
   CHARACTER(20)                :: street_name = " "
   INTEGER(2)                   :: street_number = 0
   INTEGER(2)                   :: apt_number = -1
   CHARACTER(20)                :: city = " "
   CHARACTER(2)                 :: state = "NH"
   INTEGER(4)                   :: zip = 0
   TYPE (list_node), POINTER    :: next => NULL()
END TYPE

TYPE (list_node) :: x = list_node (zip = 03054)
PRINT *, x%state, x%zip
END
```

The above prints the following:

```
        NH 3054
```

Coarrays were introduced as a Fortran 2008 feature. The following example shows a derived-type definition with a coarray component:

```
TYPE NEW_TYPE
   REAL,ALLOCATABLE,CODIMENSION[:,:,:] :: NEW(:,:,:)
END TYPE NEW_TYPE
```

An object of type NEW_TYPE must be a scalar and it cannot be a pointer, allocatable, or a coarray.

The following example shows a derived-type definition containing a *coarray-spec*:

```
type t
   integer :: k
   real, allocatable :: x (:,:)[:,:]
end type t
```

In the following example, when the assignment to DEST occurs, DEST%TA is unallocated: it is first allocated with the size of SOURCE%TA and then the value of SOURCE%TA is assigned into DEST%TA:

```
TYPE T
  INTEGER I
END TYPE T
TYPE T2
  TYPE (T), ALLOCATABLE :: TA
END TYPE T2
```

```
TYPE (T2) SOURCE, DEST

ALLOCATE(SOURCE%TA)
DEST = SOURCE
```

The use of allocatable components of recursive type can involve direct recursion, in which the type has a component that is the same type as its parent. The following example creates a five-element linked list using allocatable components of recursive type:

```
TYPE T
INTEGER I
TYPE(T), ALLOCATABLE :: NEXT
END TYPE

TYPE (T), ALLOCATABLE, TARGET :: ORIG, COPY
TYPE (T), POINTER :: TA

ALLOCATE(ORIG)
TA => ORIG

DO I=1,5
  TA%I = I
  ALLOCATE(TA%NEXT)
  TA => TA%NEXT
END DO
```

By using allocatable components rather than pointer components, there is no need to explicitly nullify component NEXT - it is set to an unallocated state automatically by the compiler. Because the semantics of ALLOCATE(SOURCE=) require the allocation and copying of all allocated allocatable components from ORIG into COPY, we can create a complete, unique copy of the entire linked list in one easy statement:

```
ALLOCATE(COPY, SOURCE=ORIG)
```

In addition to direct recursion, indirect recursion or forward referencing can also be used. In the following example, component A of type T is of type T2, a forward reference to a type not yet defined, while component B of type T2 is of type T:

```
TYPE T
TYPE(T2), ALLOCATABLE :: A
END TYPE

TYPE T2
TYPE(T), ALLOCATABLE :: B
END TYPE

TYPE(T2) TY
```

UBOUND

Inquiry Intrinsic Function (Generic): *Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.*

Syntax

`result = UBOUND (array [, dim] [, kind])`

array	(Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer. It can be an assumed-size array if *dim* is present with a value less than the rank of *array*.
dim	(Input; optional) Must be a scalar integer with a value in the range 1 to n, where *n* is the rank of *array*.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rule applies if *array* is not assumed-rank:

- If *dim* is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of *array*. Each element in the result corresponds to a dimension of *array*.

The following rules apply if *array* is assumed-rank:

- If *dim* is present and *array* is assumed-rank, the value of the result is as if *array* were a whole array, with the extent of the final dimension of *array* when *array* is associated with an assumed-size array being considered to be −1.
- If UBOUND is invoked for an assumed-rank object that is associated with a scalar and *dim* is absent, the result is a zero-sized array. UBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if *dim* is present because the rank of a scalar is zero and dim must be >= 1.

If *array* is an array section or an array expression that is not a whole array or array structure component, UBOUND(*array*, *dim*) has a value equal to the number of elements in the given dimension.

If *array* is a whole array or array structure component, UBOUND(*array*, *dim*) has a value equal to the upper bound for subscript *dim* of *array* (if *dim* is nonzero). If *dim* has size zero, the corresponding element of the result has the value zero.

The setting of compiler options specifying integer size can affect this function.

Example

Consider the following:

```
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

UBOUND (ARRAY_A) is (3, 8). UBOUND (ARRAY_A, DIM=2) is 8.

UBOUND (ARRAY_B) is (8, 20). UBOUND (ARRAY_B (5:8, :)) is (4,24) because the number of elements is significant for array section arguments.

The following shows another example:

```
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = UBOUND (ar1)          ! returns [3, 5, 14]
res2 = UBOUND (ar1, DIM= 3)  ! returns 14
res3 = UBOUND (vec1)         ! returns [35]
END
```

See Also

LBOUND

UCOBOUND

Inquiry Intrinsic Function (Generic): *Returns the upper cobounds of a coarray.*

Syntax

`result = UCOBOUND (coarray [,dim [, kind])`

coarray	(Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.
dim	(Input; optional) Must be an integer scalar with a value in the range 1 <= *dim* <= *n*, where *n* is the corank of *coarray*. The corresponding actual argument must not be an optional dummy argument.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default integer type. The result is scalar if *dim* is present; otherwise, the result is an array of rank one and size *n*, where*n* is the corank of *coarray*.

The final upper cobound is the final cosubscript in the cosubscript list for the coarray that selects the image whose index is equal to the number of images in the current team. The result depends on whether *dim* is specified:

- If *dim* is specified, UCOBOUND (COARRAY, DIM) has a value equal to the upper cobound for cosubscript *dim* of *coarray*.
- If *dim* is not specified, UCOBOUND (COARRAY) has a value whose ith element is equal to UCOBOUND (COARRAY, i), for i = 1, 2,. . . , *n*, where *n* is the corank of *coarray*.

Examples

If A is allocated by the statement ALLOCATE (A [2:3, 7:*]), then LCOBOUND (A) is [2, 7] and LCOBOUND (A, DIM=2) is 7.

If NUM_IMAGES( ) has the value 30, and coarray B is allocated by the statement ALLOCATE (B[2:3, 0:7, *]), then UCOBOUND (B) is [3, 7, 2] and UCOBOUND (B, DIM=2) is 7. Note that the cosubscripts [3, 7, 2] do not correspond to an actual image.

UNDEFINE

Statement: *Removes a defined symbol.*

See Also

See DEFINE and UNDEFINE.

UNION and END UNION

Statements: *Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.*

Syntax

Each unique field or group of fields is defined by a separate map declaration.

```
UNION
   map-declaration
   map-declaration
   [map-declaration]
   . . .
   [map-declaration]
END UNION
```

map-declaration Takes the following form:

```
MAP
   field-declaration
   [field-declaration]
   . . .
   [field-declaration]
END MAP
```

field-declaration Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.

As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.

Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.

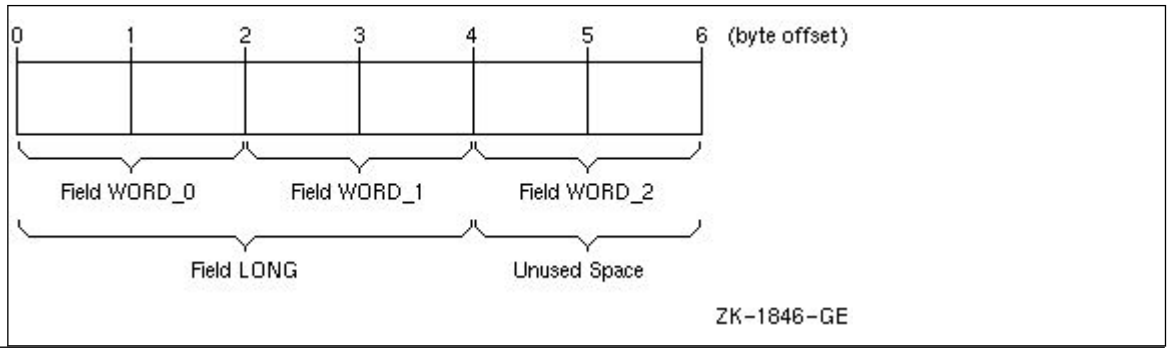
Example

In the following example, the structure WORDS_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER*2 variables (WORD_0, WORD_1, and WORD_2), and the second, an INTEGER*4 variable, LONG:

```
STRUCTURE /WORDS_LONG/
  UNION
    MAP
      INTEGER*2  WORD_0, WORD_1, WORD_2
    END MAP
    MAP
      INTEGER*4  LONG
    END MAP
  END UNION
END STRUCTURE
```

The length of any record with the structure WORDS_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS_LONG:

Memory Map of Structure WORDS_LONG



In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```
 UNION
    MAP
      CHARACTER*20 string1, CHARACTER*10 string2(6)
    END MAP
    MAP
      INTEGER*2 number(10), INTEGER*4 var(10), INTEGER*2
+      datum(10)
    END MAP
 END UNION
```

Record Structures

UNLINK

Portability Function: *Deletes the file given by path.*

Module

USE IFPORT

Syntax

`result = UNLINK (name)`

name	(Input) Character*(*). Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

- ENOENT: The specified file could not be found.
- EACCES: The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.

Example

```
USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirname
READ *, dirname
ISTATUS = UNLINK (dirname)
IF (ISTATUS) then
   print *, 'Error ', ISTATUS
END IF
END
```

DELDIRQQ

UNPACK

Transformational Intrinsic Function (Generic):
Takes elements from a rank-one array and unpacks them into another (possibly larger) array under the control of a mask.

Syntax

`result = UNPACK (vector,mask,field)`

vector	(Input) Must be a rank-one array. It may be of any data type. Its size must be at least *t*, where *t* is the number of true elements in *mask*.
mask	(Input) Must be a logical array. It determines where elements of *vector* are placed when they are unpacked.
field	(Input) Must be of the same type and type parameters as *vector* and conformable with *mask*. Elements in *field* are inserted into the result array when the corresponding *mask* element has the value false.

Results

The result is an array with the same shape as *mask*, and the same type and type parameters as *vector*.

Elements in the result array are filled in array element order. If element i of *mask* is true, the corresponding element of the result is filled by the next element in *vector*. Otherwise, it is filled by *field* (if *field* is scalar) or the ith element of *field* (if *field* is an array).

Example

N is the array

```
 [ 0  0  1 ]
 [ 1  0  1 ]
 [ 1  0  0 ],
```

P is the array (2, 3, 4, 5), and Q is the array

```
 [ T  F  F ]
 [ F  T  F ]
 [ T  T  F ].
```

UNPACK (P, MASK=Q, FIELD=N) produces the result

```
 [ 2  0  1 ]
 [ 1  4  1 ]
 [ 3  5  0 ].
```

UNPACK (P, MASK=Q, FIELD=1) produces the result

```
 [ 2  1  1 ]
 [ 1  4  1 ]
 [ 3  5  1 ].
```

The following shows another example:

```
LOGICAL mask (2, 3)
INTEGER vector(3) /1, 2, 3/, AR1(2, 3)
mask = RESHAPE((/.TRUE.,.FALSE.,.FALSE.,.TRUE.,&
                .TRUE.,.FALSE./), (/2, 3/))
! vector = [1 2 3] and mask =  T F T
!                              F T F
AR1 = UNPACK(vector, mask, 8)  ! returns  1 8 3
                               !          8 2 8
END
```

UNPACKTIMEQQ

Portability Subroutine: *Unpacks a packed time and date value into its component parts.*

Module

USE IFPORT

Syntax

```
CALL UNPACKTIMEQQ (timedate,iyr,imon,iday,ihr,imin,isec)
```

timedate	(Input) INTEGER(4). Packed time and date information.
iyr	(Output) INTEGER(2). Year (*xxxx*AD).
imon	(Output) INTEGER(2). Month (1 - 12).
iday	(Output) INTEGER(2). Day (1 - 31).
ihr	(Output) INTEGER(2). Hour (0 - 23).
imin	(Output) INTEGER(2). Minute (0 - 59).
isec	(Output) INTEGER(2). Second (0 - 59).

GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values.

The output values reflect the time zone set on the local computer and the daylight savings rules for that time zone.

Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

Example

```
USE IFPORT
CHARACTER(80)    file
TYPE (FILE$INFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec

file = 'd:\f90ps\bin\t???.*'
handle = FILE$FIRST
result = GETFILEINFOQQ(file, info, handle)
CALL UNPACKTIMEQQ(info%lastwrite, iyr, imon,&
                  iday, ihr, imin, isec)
WRITE(*,*) iyr, imon, iday
WRITE(*,*) ihr, imin, isec
END
```

UNROLL Directive for OpenMP

OpenMP* Fortran Compiler Directive: *Partially or fully unrolls a DO loop. This feature is only available for ifx.*

Syntax

```
!$OMP UNROLL [clause]
   loop-nest
[!$OMP END UNROLL]
```

clause	Is FULL or PARTIAL [(*count*)], where *count* is a compile-time integer constant expression. If FULL is specified, and *n* is the iteration count of the outermost DO loop, the outermost loop is replaced by *n* copies of the loop body.

If PARTIAL is specified, the outermost loop is first tiled with a tile size of *count*, and then the tiled loop is fully unrolled. If PARTIAL is specified without *count*, the compiler determines the count.

If *clause* is omitted, the compiler determines if and how the loop is transformed.

loop-nest Is a nest of DO loops in canonical form.

Description

The UNROLL construct applies to the outermost loop of the loop nest. It is a pure directive, so it can appear in a Fortran PURE procedure.

The transformed loop will be in canonical form only when PARTIAL is specified.

The iteration count of the outermost DO loop must be constant if FULL is specified.

Examples

In the following example, the FULL clause is specified in the UNROLL directive, so the loop iteration count must be a compile-time constant. In this case, a worksharing loop construct cannot be used because there is no loop to apply it to after the loop is unrolled.

```
INTEGER,DIMENSION (5) :: arr
INTEGER               :: i
!$OMP UNROLL FULL
DO i = 1, 5
  arr(i) = 100
END DO
```

Unrolling the above DO loops produces the following transformed code:

```
INTEGER,DIMENSION (5) :: arr
INTEGER               :: i
arr(1) = 100
arr(2) = 100
arr(3) = 100
arr(4) = 100
arr(5) = 100
```

In the following example, the loop is partially unrolled. The trip count is a multiple of *count* specified in the PARTIAL clause:

```
INTEGER,DIMENSION (64) :: arr
INTEGER                :: i
!$OMP PARALLEL DO
!$OMP UNROLL PARTIAL(4)
DO i = 1, 64
  arr(i) = arr(i) * 10
END DO
```

Unrolling the above DO loops 4 times produces the following result:

```
INTEGER,DIMENSION (64) :: arr
INTEGER                :: i
!$OMP PARALLEL DO
DO i = 0, 15
  arr(i*4 + 1) = arr(i*4 + 1) * 10
  arr(i*4 + 2) = arr(i*4 + 2) * 10
```

```
  arr(i*4 + 3) = arr(i*4 + 3) * 10
  arr(i*4 + 4) = arr(i*4 + 4) * 10
END DO
```

The following example shows how a loop with an unknown trip count that is partially unrolled may be transformed:

```
SUBROUTINE FOO (arr, n)
INTEGER               :: i,n
INTEGER,DIMENSION (n) :: arr
!$OMP PARALLEL DO
!$OMP UNROLL PARTIAL(4)
DO i = 1, n
  arr(i) = arr(i) * 10
END DO
END SUBROUTINE
```

Unrolling the above DO loop 4 times produces code equivalent to the following:

```
SUBROUTINE FOO (arr, n)
INTEGER               :: i,n
INTEGER,DIMENSION (n) :: arr
!$OMP PARALLEL DO
DO i = 0, (n+3)/4 - 1
  arr(i*4 + 1) = arr(i*4 + 1) * 10
  if ((i*4 + 2) < n) arr(i*4 + 2) = arr(i*4 + 2) * 10
  if ((i*4 + 3) < n) arr(i*4 + 3) = arr(i*4 + 3) * 10
  if ((i*4 + 4) < n) arr(i*4 + 4) = arr(i*4 + 4) * 10
END DO
END SUBROUTINE
```

UNROLL and NOUNROLL General Directives

General Compiler Directive: *Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.*

Syntax

`!DIR$ UNROLL [(n)] -or- !DIR$ UNROLL [=n]`

`!DIR$ NOUNROLL`

n Is an integer constant. The range of *n* is 0 through 255.

If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or higher must be in effect.

Example

```
!DIR$ UNROLL
  do i =1, m
    b(i) = a(i) + 1
    d(i) = c(i) + 1
  enddo
```

The following shows another example:

```
!DIR$ UNROLL= 4
  do i =1, m
    b(i) = a(c(i)) + 1
  enddo
```

UNROLL_AND_JAM and NOUNROLL_AND_JAM

General Compiler Directive: *Hints to the compiler to enable or disable loop unrolling and jamming. These directives can only be applied to iterative DO loops.*

Syntax

```
!DIR$ UNROLL_AND_JAM [(n)] -or- !DIR$ UNROLL_AND_JAM [=n]

!DIR$ NOUNROLL_AND_JAM
```

n Is an integer constant. The range of *n* is 0 through 255.

The UNROLL_AND_JAM directive partially unrolls one or more loops higher in the nest than the innermost loop and fuses (jams) the resulting loops back together. This transformation allows more reuses in the loop.

This directive is not effective on innermost loops. You must ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this directive is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler will enable this transformation whenever possible.

The UNROLL_AND_JAM directive must precede the DO statement for each DO loop it affects. If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted or if it is outside the allowed range, the optimizer chooses the number of times to unroll the loop. The compiler generates correct code by comparing *n* and the loop count.

This directive is supported only when compiler option `O3` is set. The UNROLL_AND_JAM directive overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size, it may be necessary to prevent unrolling of a nested or imperfect nested loop. In such cases, use the NOUNROLL_AND_JAM directive, which hints to the compiler not to unroll a specified loop.

Example

```
integer a(10,10), b(10,10), c(10,10), d(10,10)
integer i, j, k
```

```
!dir$ unroll_and_jam = 6

do i=1,10
  !dir$ unroll_and_jam (6)
  do j=1,10
    do k=1,10
      a (j, i) = a (j, i) + b (k, i) *c (k, j)
    end do              ! k
  end do                ! j
end do                  ! i

end
```

UNTIED Clause

Parallel Directive Clause: *Specifies that the task is never tied to the thread that started its execution.*

Syntax

`UNTIED`

Any thread in the team can resume the task region after a suspension. For example, during runtime, the execution of a given task can start on thread A, break execution, and later resume on thread B.

USE

Statement: *Gives a program unit accessibility to public entities in a module.*

Syntax

`USE [[, mod-nature] ::] name [, rename-list]`

`USE [[, mod-nature] ::] name, ONLY : [ only-list]`

mod-nature	Is INTRINSIC or NON_INTRINSIC. If INTRINSIC is used, *name* must be the name of an intrinsic module. If NON_INTRINSIC is used, *name* must be the name of a non-intrinsic module. If *mod-nature* is not specified, *name* must be the name of an intrinsic or non-intrinsic module. If both are provided, the non-intrinsic module is used. It is an error to specify a user module and an intrinsic module of the same name in the same program unit (see Examples).
name	Is the name of the module.
rename-list	Is one or more items, separated by commas, having the following form: *local-name=> mod-name*

local-name	Is the name of the entity in the program unit using the module or is "OPERATOR (*op-name*)", where *op-name* is the name of a defined operator in the program unit using the module.
mod-name	Is the name of a public entity in the module or is "OPERATOR (*op-name*)", where *op-name* is the name of a public entity in the module.

only-list Is one or more items, separated by commas, where each item is the name of a public entity in the module or a generic identifier (a generic name, a defined operator specified as "OPERATOR (*op-name*)", or defined assignment).

An entity in the *only-list* can also take the form:

[*local-name* =>] *mod-name*

Description

If the USE statement is specified without the ONLY option, the program unit has access to all public entities in the named module.

If the USE statement is specified with the ONLY option, the program unit has access to only those entities following the option.

If more than one USE statement for a given module appears in a scoping unit, the following rules apply:

- If one USE statement does not have the ONLY option, all public entities in the module are accessible, and any *rename-list*s and *only-list*s are interpreted as a single, concatenated *rename-list*.
- If all the USE statements have ONLY options, all the *only-list*s are interpreted as a single, concatenated *only-list*. Only those entities named in one or more of the *only-list*s are accessible.

If two or more generic interfaces that are accessible in a scoping unit have the same name, the same operator, or are both assignments, they are interpreted as a single generic interface. Otherwise, multiple accessible entities can have the same name only if no reference to the name is made in the scoping unit.

The local names of entities made accessible by a USE statement must not be declared locally other than in a PUBLIC, PRIVATE, VOLATILE, or ASYNCHRONOUS statement. Within a module, if a use-associated entity is declared VOLATILE or ASYNCHRONOUS, it has the default accessibility of a locally declared identifier.

The local names of use-associated entities can appear in NAMELIST group lists, but not in a COMMON or EQUIVALENCE statement.

If the name of every module from which a use-associated entity is accessed appears in an accessibility statement, the default accessibility of the entity is PRIVATE if every such accessibility statement is PRIVATE, and PUBLIC if any such accessibility statement is PUBLIC.

The accessibility of a use associated entity within a module can be determined by applying the following rules in the specified order:

1. It is PUBLIC if the entity is specified in the entity-list of a PUBLIC statement. It is PRIVATE if the entity is specified in the entity-list of a PRIVATE statement.
2. If the entity is declared locally in an ASYNCHRONOUS or VOLATILE statement, go to 5.
3. It is PUBLIC if any module through which the entity is accessible appears in a PUBLIC statement.
4. It is PRIVATE if every module thru which the entity is accessible appears in a PRIVATE statement.
5. It is PUBLIC if there is a PUBLIC statement with no entity-list specified in the module. It is PRIVATE if there is a PRIVATE statement with no entity-list specified in the module.
6. It is PUBLIC.

Examples

The following shows examples of the USE statement:

```
MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5), D(100)
END MODULE MOD_A
...
SUBROUTINE SUB_Y
  USE MOD_A, DX => D, EX => E   ! Array D has been renamed DX and array E
  ...                           ! has been renamed EX. Scalar variables B
END SUBROUTINE SUB_Y            ! and C are also available to this
...                             ! subroutine (using their module names).
SUBROUTINE SUB_Z
  USE MOD_A, ONLY: B, C         ! Only scalar variables B and C are
  ...                           !   available to this subroutine
END SUBROUTINE SUB_Z
...
```

You must not specify a user module and an intrinsic module of the same name in the same program unit. For example, if you specify a user module named ISO_FORTRAN_ENV, then it is illegal to specify the following in the same program unit:

```
USE :: ISO_FORTRAN_ENV
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

The following example shows a module containing common blocks:

```
MODULE COLORS
  COMMON /BLOCKA/ C, D(15)
  COMMON /BLOCKB/ E, F
  ...
END MODULE COLORS
...
FUNCTION HUE(A, B)
  USE COLORS
  ...
END FUNCTION HUE
```

The USE statement makes all of the variables in the common blocks in module COLORS available to the function HUE.

To provide data abstraction, a user-defined data type and operations to be performed on values of this type can be packaged together in a module. The following example shows such a module:

```
MODULE CALCULATION
  TYPE ITEM
    REAL :: X, Y
  END TYPE ITEM

  INTERFACE OPERATOR (+)
    MODULE PROCEDURE ITEM_CALC
  END INTERFACE

CONTAINS
  FUNCTION ITEM_CALC (A1, A2)
    TYPE(ITEM) A1, A2, ITEM_CALC
    ...
  END FUNCTION ITEM_CALC
  ...
```

```
END MODULE CALCULATION

PROGRAM TOTALS
USE CALCULATION
TYPE(ITEM) X, Y, Z
  ...
  X = Y + Z
  ...
END
```

The USE statement allows program TOTALS access to both the type ITEM and the extended intrinsic operator + to perform calculations.

The following shows another example:

```
! Module containing original type declarations
MODULE geometry
type square
   real side
   integer border
end type
type circle
   real radius
   integer border
end type
END MODULE

! Program renames module types for local use.
PROGRAM test
USE GEOMETRY,LSQUARE=>SQUARE,LCIRCLE=>CIRCLE
! Now use these types in declarations
type (LSQUARE) s1,s2
type (LCIRCLE) c1,c2,c3
```

The following shows a defined operator in a USE statement:

```
  USE mymod, OPERATOR(.localop.) => OPERATOR(.moduleop.)
```

Entities in modules can be accessed either through their given name, or through aliases declared in the USE statement of the main program unit. For example:

```
  USE MODULE_LIB, XTABS => CROSSTABS
```

This statement accesses the routine called `CROSSTABS` in `MODULE_LIB` by the name `XTABS`. This way, if two modules have routines called `CROSSTABS`, one program can use them both simultaneously by assigning a local name in its USE statement.

When a program or subprogram renames a module entity, the local name (`XTABS`, in the preceding example) is accessible throughout the scope of the program unit that names it.

The ONLY option also allows public variables to be renamed. Consider the following:

```
  USE MODULE_A, ONLY: VARIABLE_A => VAR_A
```

In this case, the host program accesses only `VAR_A` from module `A`, and refers to it by the name `VARIABLE_A`.

Consider the following example:

```
MODULE FOO
   integer foos_integer
 PRIVATE
   integer foos_my_integer
END MODULE FOO
```

PRIVATE, in this case, makes the PRIVATE attribute the default for the entire module `FOO`. To make `foos_integer` accessible to other program units, add the line:

```
PUBLIC :: foos_integer
```

Alternatively, to make only `foos_my_integer` inaccessible outside the module, rewrite the module as follows:

```
MODULE FOO
  integer foos_integer
  integer, private::foos_my_integer
END MODULE FOO
```

Given the following module declarations:

```
MODULE mod1
  INTEGER x1
END MODULE

MODULE mod2
  USE mod1
  INTEGER x2
END MODULE
```

Then in module mod3 below, x1 has default accessibility of PRIVATE:

```
MODULE mod3
  USE mod2
  PUBLIC x2     ! x2 is PUBLIC
  PRIVATE       ! x1 is PRIVATE
END MODULE
```

In mod4 below, even though x1 is declared in mod1, and mod1 is declared PRIVATE in mod4, x1 is PUBLIC since it is declared VOLATILE and it assumes the default accessibility of PUBLIC of a locally declared identifier in mod4:

```
MODULE mod4
  USE mod1
  PRIVATE mod1
  VOLATILE x1    ! x1 is PUBLIC
END MODULE
```

In mod5 below, x1 and x2 are both PRIVATE since all modules from which they are accessed appear in PRVATE statements:

```
MODULE mod5
  USE mod1
  USE mod2
  PRIVATE mod1
  PRIVATE mod2   ! x1 and x2 are PRIVATE
END MODULE
```

However, in mod6 below, both x1 and x2 are PUBLIC since they are accessible thru the use of mod2 which is declared PUBLIC:

```
MODULE mod6
  USE mod1
  USE mod2
  PRIVATE mod1
  PUBLIC mod2    !  x1 and x2 are PUBLIC
END MODULE
```

Program Units and Procedures

USE_DEVICE_PTR Clause

Parallel Directive Clause: *Tells the construct to use a device pointer currently in the device data environment.*

Syntax

`USE_DEVICE_PTR (`*`ptr-list`*`)`

ptr-list	Is a list of one or more variables of type C_PTR from the intrinsic module ISO_C_BINDING[1]. The pointers are converted into device pointers to the corresponding list item in the device data environment.

[1] List items not of type C_PTR have been deprecated in the OpenMP* specification.

The pointers listed in *ptr-list* become private pointers in the device data environment. The device pointers to the corresponding list items in the device data environment are assigned to the private pointers.

References in the construct to a *ptr-list* item that appears in this clause must be to the address of the *ptr-list* item.

%VAL

Built-in Function: *Changes the form of an actual argument. Passes the argument as an immediate value.*

Syntax

`%VAL (`*`a`*`)`

a	(Input) An expression, record name, procedure name, array, character array section, or array element.

Description

The argument is passed as follows:

- On IA-32 architecture, as a 32-bit immediate value. If the argument is integer (or logical) and shorter than 32 bits, it is sign-extended to a 32-bit value. For complex data types, %VAL passes two 32-bit arguments.
- On Intel® 64 architecture, as a 64-bit immediate value. If the argument is integer (or logical) and shorter than 64 bits, it is sign-extended to a 64-bit value. For complex data types, %VAL passes two 64-bit arguments.

You must specify %VAL in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following tables list the Intel® Fortran defaults for argument passing, and the allowed uses of %VAL:

Expressions

Actual Argument Data Type	Default	%VAL
Logical	REF	Yes[1]
Integer	REF	Yes[1]
REAL(4)	REF	Yes
REAL(8)	REF	No
REAL(16)	REF	No
COMPLEX(4)	REF	Yes
COMPLEX(8)	REF	Yes
COMPLEX(16)	REF	No
Character	See table note [2]	No
Hollerith	REF	No
Aggregate[3]	REF	No
Derived	REF	No

Array Name

Actual Argument Data Type	Default	%VAL
Numeric	REF	No
Character	See table note [2]	No
Aggregate[3]	REF	No
Derived	REF	No

Procedure Name

Actual Argument Data Type	Default	%VAL
Numeric	REF	No
Character	See table note [2]	No

[1] If a logical or integer value occupies less than 64 bits of storage on Intel® 64 architecture, or 32 bits of storage on IA-32 architecture, it is converted to the correct size by sign extension. Use the ZEXT intrinsic function if zero extension is desired.

[2] A character argument is passed by address and hidden length.

[3] In Intel® Fortran record structures

The %VAL and %REF functions override related !DIR$ ATTRIBUTE settings.

Example

```
CALL SUB(2, %VAL(2))
```

Constant 2 is passed by reference. The second constant 2 is passed by immediate value.

See Also

CALL

%REF
%LOC

VALUE

Statement and Attribute: *Specifies a type of argument association for a dummy argument.*

Syntax

The VALUE attribute can be specified in a type declaration statement or a VALUE statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] VALUE [, *att-ls*] :: *arg* [, *arg*] ...

Statement:

VALUE [::] *arg* [, *arg*]...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
arg	Is the name of a dummy argument.

Description

The VALUE attribute can be used in INTERFACE body or in a procedure. It can only be specified for dummy arguments. It cannot be specified for a dummy procedure.

An entity with the VALUE attribute must be a dummy data object that is not an assumed-size array or a coarray, and does not have a coarray ultimate component.

When this attribute is specified for a present dummy argument, the dummy argument becomes associated with a temporary, definable data object whose initial value is that of the corresponding actual argument. The actual mechanism by which this happens is determined by the compiler. If the procedure also has the BIND(C) attribute, the dummy argument is interoperable with the corresponding formal parameter of the C language prototype, causing the argument to be passed or received by value if C would do so.

When the VALUE attribute is used in a type declaration statement, any length type parameter values must be omitted or they must be specified by initialization expressions.

If the VALUE attribute is specified, you cannot specify a PARAMETER, EXTERNAL, POINTER, ALLOCATABLE, VOLATILE, or INTENT (INOUT or OUT) attribute in the same scoping unit. Additionally, you cannot specify both the OPTIONAL attribute and the VALUE attribute for a dummy argument to a procedure with the BIND attribute.

You can use option assume nostd_value to tell the compiler to use non-standard semantics for VALUE so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.

Example

The following example shows how the VALUE attribute can be applied in a type declaration statement.

```
j = 3
call sub (j)
write (*,*) j ! Writes 3
contains
subroutine sub (i)
integer, value :: I
i = 4
```

```
write (*,*) i ! Writes 4
end subroutine sub
end
```

VECREMAINDER Clause

General Directive Clause: *Allows the compiler to vectorize (or not to vectorize) any peel or remainder loops when the original loop is vectorized.*

Syntax

`[NO]VECREMAINDER`

If !DIR$ VECTOR ALWAYS is specified, the following occurs:

- If VECREMAINDER is specified, the compiler vectorizes peel and remainder loops when the original main loop is vectorized.
- If NOVECREMAINDER is specified, the compiler does not vectorize peel or remainder loops when the original main loop is vectorized.
- If neither the VECREMAINDER or NOVECREMAINDER clause is specified, the compiler overrides efficiency heuristics of the vectorizer and it determines whether the loop can be vectorized.

See Also

VECTOR and NOVECTOR
SIMD Loop Directive

VECTOR and NOVECTOR

General Compiler Directive: *Overrides default heuristics for vectorization of DO loops. It can also affect certain optimizations.*

Syntax

`!DIR$ VECTOR [clause[[,] clause]...]`

`!DIR$ NOVECTOR`

clause

Is an optional vectorization or optimizer clause. It can be one or more of the following:

- `ALIGNED | UNALIGNED`

  Specifies that all data is aligned or no data is aligned in a DO loop. These clauses override efficiency heuristics in the optimizer.

  The ALIGNED clause instructs the compiler to assume all array references are aligned. As a result, misalignment properties analyzed from the program context, if any, will be discarded. The UNALIGNED clause is a hint to the compiler to avoid alignment optimizations; the compiler can still use available alignment

information. These clauses disable advanced alignment optimizations of the compiler, such as dynamic or static loop peeling to make references aligned.

Be careful when using the ALIGNED clause. The compiler may choose to use aligned data movement instructions, instructions with memory operands that require alignment, and/or nontemporal stores. Such instructions will cause a runtime exception if some of the access patterns are actually unaligned.

- `ALWAYS [ASSERT]`

  Enables or disables vectorization of a DO loop.

  The ALWAYS clause overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized. You should use the IVDEP directive to ignore assumed dependences.
- `DYNAMIC_ALIGN [(`*var*`)] | NODYNAMIC_ALIGN]`

  Enables or disables dynamic alignment optimization. Dynamic alignment is an optimization the compiler attempts to perform by default. It involves peeling iterations from the vector loop into a scalar loop before the vector loop so that the vector loop aligns with a particular memory reference.

  If you specify (*var*) for DYNAMIC_ALIGN, you can indicate a scalar or array variable name on which to align. Specifying DYNAMIC_ALIGN, with or without (*var*) does not guarantee the optimization is performed; the compiler still uses heuristics to determine feasibility of the optimization. The NODYNAMIC_ALIGN clause disables the optimization for the loop.
- `MASK_READWRITE | NOMASK READWRITE`

  Enables or disables the generation of masked load and store operations within conditional statements.

  The MASK_READWRITE clause directs the compiler to disable memory speculation, causing the generation of masked load and store operations within conditional statements. The NOMASK_READWRITE clause directs the compiler to enable memory speculation, causing the generation of unmasked loads and stores within conditional statements.
- `[NO]MULTIPLE_GATHER_SCATTER_BY_SHUFFLES` (can also be specified as `[NO]G2S`, which is deprecated)

  Enables or disables the optimization for multiple adjacent gathers/scatters.

  The `MULTIPLE_GATHER_SCATTER_BY_SHUFFLES` clause is an optimization hint to encourage use of unit-strided loads/stores plus a set of shuffles instead of multiple gathers/scatters (or straightforward gather/scatter emulation software sequences). The `NOMULTIPLE_GATHER_SCATTER_BY_SHUFFLES` clause tells the compiler not to try optimizing multiple gathers/scatters into unit-strided loads/stores plus a set of shuffles.

- `TEMPORAL` | `NONTEMPORAL` [(*var1* [, *var2*]...)]

  var Is an optional memory reference in the form of a variable name.

  Controls how the "stores" of register contents to memory are performed (streaming versus non-streaming).

  The TEMPORAL clause directs the compiler to use temporal (that is, non-streaming) stores. The NONTEMPORAL clause directs the compiler to use non-temporal (that is, streaming) stores.

  By default, the compiler automatically determines whether a streaming store should be used for each variable.

  Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.
- [NO]VECREMAINDER
- `VECTORLENGTH` (*n*1 [, *n*2]…)

  Tells the vectorizor which vector length/factor to use when generating the main vector loop. *n* is an integer power of 2; the value must be 2, 4, 8, 16, 32, or 64. If more than one value is specified, the vectorizor will choose one of the specified vector lengths based on a cost model decision.

The VECTOR and NOVECTOR directives control vectorization of the DO loop that directly follows the directive.

If the `MASK_READWRITE` clause is specified, the compiler generates masked loads and stores within all conditional branches in the loop. If the `NOMASK_READWRITE` clause is specified, the compiler generates unmasked loads and stores for increased performance.

Caution
The VECTOR directive should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Example

The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).

In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```
!DIR$ VECTOR ALWAYS
  do i = 1, 100, 2
    ! two references with stride 2 follow
    a(i) = b(i)
  enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the NOVECTOR directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```
!DIR$ NOVECTOR
  do i = 1, 100
    a(i) = b(i) + c(i)
  enddo
```

VERIFY

Elemental Intrinsic Function (Generic): *Verifies that a set of characters contains all the characters in a string by identifying the first character in the string that is not in the set.*

Syntax

`result = VERIFY (string, set [, back] [, kind])`

string	(Input) Must be of type character.
set	(Input) Must be of type character with the same kind parameter as *string*.
back	(Input; optional) Must be of type logical.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *back* is omitted (or is present with the value false) and *string* has at least one character that is not in *set*, the value of the result is the position of the leftmost character of *string* that is not in *set*.

If *back* is present with the value true and *string* has at least one character that is not in *set*, the value of the result is the position of the rightmost character of *string* that is not in *set*.

If each character of *string* is in *set* or the length of *string* is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

Example

VERIFY ('CDDDC', 'C') has the value 2.

VERIFY ('CDDDC', 'C', BACK=.TRUE.) has the value 4.

VERIFY ('CDDDC', 'CD') has the value zero.

The following shows another example:

```
INTEGER(4) position

position = VERIFY ('banana', 'nbc')  ! returns 2
position = VERIFY ('banana', 'nbc', BACK=.TRUE.)
                                     ! returns 6
position = VERIFY ('banana', 'nbca') ! returns 0
```

SCAN

VIRTUAL

Statement: *Has the same form and effect as the DIMENSION statement. It is included for compatibility with PDP-11 FORTRAN.*

See Also

DIMENSION

VOLATILE

Statement and Attribute: *Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. It prevents objects from being optimized during compilation.*

Syntax

The VOLATILE attribute can be specified in a type declaration statement or a VOLATILE statement, and takes one of the following forms:

Type Declaration Statement:

type, [*att-ls*,] VOLATILE [, *att-ls*] :: *object*[, *object*] ...

Statement:

VOLATILE [::] *object*[, *object*] ...

type	Is a data type specifier.
att-ls	Is an optional list of attribute specifiers.
object	Is the name of an object, or the name of a common block enclosed in slashes.

A variable or COMMON block must be declared VOLATILE if it can be read or written in a way that is not visible to the compiler. For example:

- If an operating system feature is used to place a variable in shared memory (so that it can be accessed by other programs), the variable must be declared VOLATILE.
- If a variable is accessed or modified by a routine called by the operating system when an asynchronous event occurs, the variable must be declared VOLATILE.

If an array is declared VOLATILE, each element in the array becomes volatile. If a common block is declared VOLATILE, each variable in the common block becomes volatile.

If an object of derived type is declared VOLATILE, its components become volatile.

If a pointer is declared VOLATILE, the pointer itself becomes volatile.

A VOLATILE statement cannot specify the following:

- A procedure
- A namelist group

The VOLATILE attribute must not be specified for a coarray that is accessed by use or host association. A noncoarray object that has the VOLATILE attribute can be associated with an object that does not have the VOLATILE attribute, including by use or host association. A data object with the VOLATILE attribute may not be declared in a PURE procedure or referenced by a PURE statement function.

Example

The following example shows a type declaration statement specifying the VOLATILE attribute:

```
INTEGER, VOLATILE :: D, E
```

The following example shows a VOLATILE statement:

```
PROGRAM TEST
LOGICAL(KIND=1) IPI(4)
INTEGER(KIND=4) A, B, C, D, E, ILOOK
INTEGER(KIND=4) P1, P2, P3, P4
COMMON /BLK1/A, B, C
VOLATILE /BLK1/, D, E
EQUIVALENCE(ILOOK, IPI)
EQUIVALENCE(A, P1)
EQUIVALENCE(P1, P4)
```

The named common block, BLK1, and the variables D and E are volatile. Variables P1 and P4 become volatile because of the direct equivalence of P1 and the indirect equivalence of P4.

WAIT

Statement: *Performs a wait operation for a specified pending asynchronous data transfer operation. It takes one of the following forms:*

Syntax

`WAIT([UNIT=]`*`io-unit`* `[, END=`*`label`*`] [, EOR=`*`label`*`] [, ERR=`*`label`*`] [, ID=`*`id-var`*`] [, IOMSG=`*`msg-var`*`] [, IOSTAT=`*`i-var`*`])`

`WAIT` *`io-unit`*

`io-unit`	(Input) Is an external unit specifier.
`label`	(Input) Is the label of the branch target statement that receives control if an error occurs.
`id-var`	(Input) Is a scalar integer variable that is the identifier of a pending data transfer operation for the specified unit. If it is specified, a wait operation is performed for that pending operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.
`msg-var`	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
`i-var`	(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

A wait operation completes the processing of a pending data transfer operation. Each wait operation completes only a single data transfer operation, although a single statement may perform multiple wait operations.

The WAIT statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The EOR= specifier only has effect if the pending data transfer operation is a nonadvancing read. The END= specifier only has effect if the pending data transfer operation is a READ.

Example

The following example shows how the WAIT statement can be applied.

```
program test
integer, asynchronous, dimension(100) :: array
open (unit=1,file='asynch.dat',asynchronous='YES',&
  form='unformatted')
write (1) (i,i=1,100)
rewind (1)
read (1,asynchronous='YES') array
wait(1)
write (*,*) array(1:10)
end
```

WHERE

Statement and Construct: *Lets you use masked array assignment, which performs an array operation on selected elements. This kind of assignment applies a logical test to an array on an element-by-element basis.*

Syntax

Statement:

`WHERE (`*`mask-expr1`*`) `*`assign-stmt`*

Construct:

[*name*:]WHERE (*mask-expr1*)

    [*where-body-stmt*] ...

[ELSE WHERE(*mask-expr2*) [*name*]

    [*where-body-stmt*] ...]

[ELSE WHERE[*name*]

    [*where-body-stmt*] ...]

END WHERE [*name*]

mask-expr1, mask-expr2	Are logical array expressions (called mask expressions).
assign-stmt	Is an assignment statement of the form: array variable = array expression.
name	Is the name of the WHERE construct.
where-body-stmt	Is one of the following: • An *assign-stmt*

The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.

- A WHERE statement or construct

Description

If a construct *name* is specified in a WHERE statement, the same name must appear in the corresponding END WHERE statement. The same construct name can optionally appear in any ELSE WHERE statement in the construct. (ELSE WHERE cannot specify a different name.)

In each assignment statement, the mask expression, the variable being assigned to, and the expression on the right side, must all be conformable. Also, the assignment statement cannot be a defined assignment.

Only the WHERE statement (or the first line of the WHERE construct) can be labeled as a branch target statement.

The following shows an example using a WHERE statement:

```
INTEGER A, B, C
DIMENSION A(5), B(5), C(5)
DATA A /0,1,1,1,0/
DATA B /10,11,12,13,14/
C = -1

WHERE(A .NE. 0) C = B / A
```

The resulting array C contains: -1,11,12,13, and -1.

The assignment statement is only executed for those elements where the mask is true. Think of the mask expression as being evaluated first into a logical array that has the value true for those elements where A is positive. This array of trues and falses is applied to the arrays A, B and C in the assignment statement. The right side is only evaluated for elements for which the mask is true; assignment on the left side is only performed for those elements for which the mask is true. The elements for which the mask is false do not get assigned a value.

In a WHERE construct, the mask expression is evaluated first and only once. Every assignment statement following the WHERE is executed as if it were a WHERE statement with " *mask-expr1*" and every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. *mask-expr1*". If ELSE WHERE specifies "*mask-expr2*", it is executed as "(.NOT. *mask-expr1*) .AND. *mask-expr2*" during the processing of the ELSE WHERE statement.

You should be careful if the statements have side effects, or modify each other or the mask expression.

The following is an example of the WHERE construct:

```
DIMENSION PRESSURE(1000), TEMP(1000), PRECIPITATION(1000)
WHERE(PRESSURE .GE. 1.0)
  PRESSURE = PRESSURE + 1.0
  TEMP = TEMP - 10.0
ELSEWHERE
  PRECIPITATION = .TRUE.
ENDWHERE
```

The mask is applied to the arguments of functions on the right side of the assignment if they are considered to be elemental functions. Only elemental intrinsics are considered elemental functions. Transformational intrinsics, inquiry intrinsics, and functions or operations defined in the subprogram are considered to be nonelemental functions.

Consider the following example using LOG, an elemental function:

```
WHERE(A .GT. 0)  B = LOG(A)
```

The mask is applied to A, and LOG is executed only for the positive values of A. The result of the LOG is assigned to those elements of B where the mask is true.

Consider the following example using SUM, a nonelemental function:

```
REAL A, B
DIMENSION A(10,10), B(10)
WHERE(B .GT. 0.0)  B = SUM(A, DIM=1)
```

Since SUM is nonelemental, it is evaluated fully for all of A. Then, the assignment only happens for those elements for which the mask evaluated to true.

Consider the following example:

```
REAL A, B, C
DIMENSION A(10,10), B(10), C(10)
WHERE(C .GT. 0.0)  B = SUM(LOG(A), DIM=1)/C
```

Because SUM is nonelemental, all of its arguments are evaluated fully regardless of whether they are elemental or not. In this example, LOG(A) is fully evaluated for all elements in A even though LOG is elemental. Notice that the mask is applied to the result of the SUM and to C to determine the right side. One way of thinking about this is that everything inside the argument list of a nonelemental function does not use the mask, everything outside does.

Example

```
REAL(4) a(20)
. . .
WHERE (a > 0.0)
  a = LOG (a)
     !LOG is invoked only for positive elements
END WHERE
```

FORALL

Arrays

WORKSHARE

OpenMP* Fortran Compiler Directive: *Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.*

Syntax

```
!$OMP WORKSHARE [NOWAIT]
   loosely-structured-block
!$OMP END WORKSHARE [NOWAIT]
```

-or-

```
!$OMP WORKSHARE [NOWAIT]
   strictly-structured-block
[!$OMP END WORKSHARE [NOWAIT]]
```

loosely-structured-block	Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block	Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The *loosely-structured-block* or *strictly-structured-block* is executed so that each statement is completed before the next statement is started and the evaluation of the right hand side of an assignment is completed before the effects of assigning to the left hand side occur.

The following are additional rules for the block:

- It may contain statements that bind to lexically enclosed PARALLEL constructs. Statements in these PARALLEL constructs are not restricted.
- It may contain ATOMIC directives and CRITICAL constructs.
- It must only contain array assignment statements, scalar assignment statements, FORALL statements, FORALL constructs, WHERE statements, or WHERE constructs.
- It must not contain any user-defined function calls unless the function is ELEMENTAL.

The binding thread set for a WORKSHARE construct is the current team. A workshare region binds to the innermost enclosing parallel region.

If you do not specify the NOWAIT keyword, synchronization is implied following the code. NOWAIT can appear in either the beginning WORKSHARE directive, or in the END WORKSHARE directive, but not in both for the same WORKSHARE construct.

Multithreaded code is not always generated for the statements inside the block of an OMP WORKSHARE construct. Some statements parallelize; others do not parallelize and instead execute sequentially inside an OMP SINGLE construct to preserve the correct semantics of WORKSHARE. Some specific details follow:

- Simple array assignments such as A = B + C parallelize.
- Simple array assignments with overlap such as A = A + B + C parallelize.
- Array assignments with user-defined function calls parallelize such as A = A + F (B). F must be ELEMENTAL.
- Array assignments with array slices on the right hand side of the assignment such as A = A + B(1:4) + C(1:4) parallelize. If the lower bound of the left hand side or the array slice lower bound or the array slice stride on the right hand side is not 1, then the statement does not parallelize.
- Assigning into array slices does not parallelize.
- Scalar assignments do not parallelize – there is no work that needs to be done in parallel.
- FORALL and WHERE constructs do not parallelize.

WRITE Statement

Statement: *Transfers output data to external sequential, direct-access, or internal records.*

Syntax

Sequential

Formatted:

```
WRITE (eunit, format [, advance] [, asynchronous] [, decimal] [, id] [, pos] [, round] [, sign] [, iostat] [ , err] [, [iomsg])[io-list]
```

Formatted - List-Directed:

```
WRITE (eunit, * [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round] [, sign] [, iostat] [, err] [, iomsg])[io-list]
```

Formatted - Namelist:

```
WRITE (eunit, nml-group [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round]
[, sign] [, iostat] [, err] [, iomsg])
```

Unformatted:

```
WRITE (eunit [, asynchronous] [, id] [, pos] [, iostat] [, err] [, iomsg])[io-list]
```

Direct-Access

Formatted:

```
WRITE (eunit, format, rec [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round]
[, sign] [, iostat] [, err] [, iomsg])[io-list]
```

Unformatted:

```
WRITE (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [ , err] [, iomsg])[io-list]
```

Internal

```
WRITE (iunit, format [, nml-group] [, iostat] [ , err] [, iomsg])[io-list]
```

Internal Namelist

```
WRITE (iunit, nml-group [, iostat] [ , err] [, iomsg])[io-list]
```

eunit	Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if *eunit* is not the first specifier in the list.
format	Is a format specifier. It is optionally prefaced by FMT= if *format* is the second specifier in the list and the first specifier indicates a logical or internal unit specifier *without* the optional keyword UNIT=.
advance	Is an advance specifier (ADVANCE=*c-expr*). If the value of *c-expr* is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.
asynchronous	Is an asynchronous specifier (ASYNCHRONOUS=*i-expr*). If the value of *i-expr* is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.
decimal	Is a decimal mode specifier (DECIMAL=*dmode*) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.
delim	Is a delimiter specifier (DELIM=*del*). If the value of *del* is 'APOSTROPHE', apostrophes delimit character constants. If the value is 'QUOTE', quotes delimit character constants. If the value of del is 'NONE', character constants have no delimiters.
id	Is an id specifier (ID=*id-var*). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.
pos	Is a pos specifier (POS=*p*) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified for a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

round	Is a rounding specifier (ROUND=*rmode*) that determines the I/O rounding mode for this WRITE statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.
sign	Is a plus sign specifier (SIGN=*sn*). This controls whether optional plus characters appear in formatted numeric output.
iostat	Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.
err	Are branch specifiers if an error (ERR=*label*) condition occurs.
iomsg	Is an I/O message specifier (IOMSG=*msg-var*).
io-list	Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.
form	Is the nonkeyword form of a format specifier (no FMT=).
*	Is the format specifier indicating list-directed formatting. (It can also be specified as FMT= *.)
nml-group	Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if *nml-group* is not the second I/O specifier. For more information, see Namelist Specifier.
rec	Is the cell number of a record to be accessed directly. It must be prefaced by REC=.
iunit	Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if *iunit* is not the first specifier in the list. It must be a character variable. It must not be an array section with a vector subscript. If an item in *io-list* is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as *eunit*.

If you specify DECIMAL=, ROUND=, or SIGN= you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Example

```
! write to file
open(1,FILE='test.dat')
write (1, '(A20)') namedef
! write with FORMAT statement
WRITE (*, 10) (n, SQRT(FLOAT(n)), FLOAT(n)**(1.0/3.0), n = 1, 100)
10 FORMAT (I5, F8.4, F8.5)
```

The following shows another example:

```
WRITE(6,'("Expected ",F12.6)') 2.0
```

XOR

Elemental Intrinsic Function (Generic): *An alternative name for intrinsic function IEOR.*

See Also

See IEOR.

ZEXT

Elemental Intrinsic Function (Generic): *Extends an argument with zeros. This function is used primarily for bit-oriented operations. It cannot be passed as an actual argument.*

Syntax

```
result = ZEXT (x [,kind])
```

x	(Input) Must be of type logical or integer.
kind	(Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is *x* extended with zeros and treated as an unsigned value.

The storage requirements for integer constants are never less than two bytes. Integer constants within the range of constants that can be represented by a single byte still require two bytes of storage.

The setting of compiler options specifying integer size can affect this function.

Specific Name [1]	Argument Type	Result Type
IZEXT	LOGICAL(1)	INTEGER(2)
	LOGICAL(2)	INTEGER(2)
	INTEGER(1)	INTEGER(2)
	INTEGER(2)	INTEGER(2)
JZEXT	LOGICAL(1)	INTEGER(4)
	LOGICAL(2)	INTEGER(4)
	LOGICAL(4)	INTEGER(4)
	INTEGER(1)	INTEGER(4)

Specific Name [1]	Argument Type	Result Type
	INTEGER(2)	INTEGER(4)
	INTEGER(4)	INTEGER(4)
KZEXT	LOGICAL(1)	INTEGER(8)
	LOGICAL(2)	INTEGER(8)
	LOGICAL(4)	INTEGER(8)
	LOGICAL(8)	INTEGER(8)
	INTEGER(1)	INTEGER(8)
	INTEGER(2)	INTEGER(8)
	INTEGER(4)	INTEGER(8)
	INTEGER(8)	INTEGER(8)

[1]These specific functions cannot be passed as actual arguments.

Example

Consider the following example:

```
INTEGER(2) W_VAR  /'FFFF'X/
INTEGER(4) L_VAR
L_VAR = ZEXT( W_VAR )
```

This example stores an INTEGER(2) quantity in the low-order 16 bits of an INTEGER(4) quantity, with the resulting value of L_VAR being '0000FFFF'X. If the ZEXT function had not been used, the resulting value would have been 'FFFFFFFF'X, because W_VAR would have been converted to the left-hand operand's data type by sign extension.

POSIX* Library Routines

This section contains descriptions of the POSIX* library routines. They are listed in alphabetical order.

To access the POSIX library, you must specify a USE IFPOSIX statement in your program.

Certain POSIX* routines are restricted to Linux* systems. If a routine is restricted, it will say that in the description.

IPXFARGC

POSIX Function: *Returns the index of the last command-line argument.*

Module

USE IFPOSIX

Syntax

```
result = IPXFARGC( )
```

Results

The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.

See Also

PXFGETARG

IPXFCONST

POSIX Function: *Returns the value associated with a constant defined in the C POSIX standard.*

Module

USE IFPOSIX

Syntax

```
result = IPXFCONST (constname)
```

constname	(Input) Character. The name of a C POSIX standard constant.

Results

The result type is INTEGER(4). If *constname* corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is -1.

See Also

PXFGETARG
PXFCONST

IPXFLENTRIM

POSIX Function: *Returns the index of the last non-blank character in an input string.*

Module

USE IFPOSIX

Syntax

```
result = IPXFLENTRIM (string)
```

string	(Input) Character. A character string.

Results

The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument *string*, or zero if all characters in *string* are blank characters.

IPXFWEXITSTATUS

POSIX Function: *Returns the exit code of a child process. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

```
result = IPXFWEXITSTATUS (istat)
```

istat	(Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

Results

The result type is INTEGER(4). The result is the low-order eight bits of the output argument of PXFWAIT or PXFWAITPID.

The IPXFWEXITSTATUS function should only be used if PXFWIFEXITED returns TRUE.

Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *," the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET,IERROR)
  if(IPID.EQ.0) then
     print *," I am a child process"
     print *," My child's pid is", IPID_RET
     call PXFGETPPID(IPID_RET,IERROR)
     print *," The pid of my parent is",IPID_RET
     print *," Now I have exited with code 0xABCD"
     call PXFEXIT(Z'ABCD')
  else
     print *," I am a parent process"
     print *," My parent pid is ", IPID_RET
     print *," I am creating the process with pid", IPID
     print *," Now I am waiting for the end of the child process"
     call PXFWAIT(ISTAT, IPID_RET, IERROR)
     print *," The child with pid ", IPID_RET," has exited"
     if( PXFWIFEXITED(ISTAT) ) then
       print *, " The child exited normally"
       istat_ret = IPXFWEXITSTATUS(ISTAT)
       print 10," The low byte of the child exit code is", istat_ret
     end if
  end if
10 FORMAT (A,Z)
end program
```

IPXFWSTOPSIG

POSIX Function: *Returns the number of the signal that caused a child process to stop.* *This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`result = IPXFWSTOPSIG (istat)`

istat	(Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

Results

The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop.

The IPXFWSTOPSIG function should only be used if PXFWIFSTOPPED returns TRUE.

See Also

PXFWAIT
PXFWAITPID
PXFWIFSTOPPED

IPXFWTERMSIG

POSIX Function: *Returns the number of the signal that caused a child process to terminate. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

```
result = IPXFWTERMSIG (istat)
```

istat	(Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

Results

The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.

The IPXFWTERMSIG function should only be used if PXFWIFSIGNALED returns TRUE.

See Also

PXFWAIT
PXFWAITPID
PXFWIFSIGNALED

PXFGET

POSIX Subroutine: *Gets the value stored in a component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

```
CALL PXF(type)GET (jhandle,compname,value,ierror)
CALL PXF(type)GET (jhandle,compname,value,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFINTGET
REAL	REAL(4)	PXFREALGET

Value	Data Type	Routine Name
LGCL	LOGICAL(4)	PXFLGCLGET
STR	CHARACTER*(*)	PXFSTRGET
CHAR	CHARACTER(1)	PXFCHARGET
DBL	REAL(8)	PXFDBLGET
INT8	INTEGER(8)	PXFINT8GET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

value (Output) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). Stores the value of the component (or field).

ilen (Output) INTEGER(4). This argument can only be used when *(type)* is STR (PXFSTRGET). Stores the length of the returned string.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXF(type)GET subroutines retrieve the value from component (or field) *compname* of the structure associated with handle *jhandle* into variable *value*.

Example

See the example in PXFTIMES (which shows PXFINTGET and PXFINT8GET)

See Also

PXF(type)SET

PXFSET

POSIX Subroutine: *Sets the value of a component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

```
CALL PXF(type)SET (jhandle,compname,value,ierror)
CALL PXF(type)SET (jhandle,compname,value,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFINTSET
REAL	REAL(4)	PXFREALSET

Value	Data Type	Routine Name
LGCL	LOGICAL(4)	PXFLGCLSET
STR	CHARACTER*(*)	PXFSTRSET
CHAR	CHARACTER(1)	PXFCHARSET
DBL	REAL(8)	PXFDBLSET
INT8	INTEGER(8)	PXFINT8SET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to write data to.

value (Input) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). The value for the component (or field).

ilen (Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFSTRSET). The length of the string in *value*.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Example

See the example in PXFSTRUCTCREATE (which shows PXFSTRSET)

See Also

PXF(type)GET

PXFAGET

POSIX Subroutine: *Gets the array values stored in a component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

```
CALL PXFA(type)GET (jhandle,compname,value,ialen,ierror)
CALL PXFA(type)GET (jhandle,compname,value,ialen,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFAINTGET
REAL	REAL(4)	PXFAREALGET
LGCL	LOGICAL(4)	PXFALGCLGET

Value	Data Type	Routine Name
STR	CHARACTER*(*)	PXFASTRGET
CHAR	CHARACTER(1)	PXFACHARGET
DBL	REAL(8)	PXFADBLGET
INT8	INTEGER(8)	PXFAINT8GET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

value (Output) An array, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).

ialen (Input) INTEGER(4). The size of array *value*.

ilen (Output) INTEGER(4). This argument can only be used when *(type)* is STR (PXFASTRGET). An array that stores the lengths of elements of array *value*.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

See Also

PXFA(type)SET
PXF(type)GET

PXFASET

POSIX Subroutine: *Sets the value of an array component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

```
CALL PXFA(type)SET (jhandle, compname,value,ialen,ierror)
CALL PXFA(type)SET (jhandle,compname,value,ialen,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFAINTSET

Value	Data Type	Routine Name
REAL	REAL(4)	PXFAREALSET
LGCL	LOGICAL(4)	PXFALGCLSET
STR	CHARACTER*(*)	PXFASTRSET
CHAR	CHARACTER(1)	PXFACHARSET
DBL	REAL(8)	PXFADBLSET
INT8	INTEGER(8)	PXFAINT8SET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to write data to.

value (Input) An array, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type of the array is INTEGER(4). The value for the component (or field).

ialen (Input) INTEGER(4). The size of array *value*.

ilen (Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFASTRSET). An array that specifies the lengths of elements of array *value*.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

PXFA(type)GET
PXF(type)SET

PXFACCESS

POSIX Subroutine: *Determines the accessibility of a file.*

Module

USE IFPOSIX

Syntax

```
CALL PXFACCESS (path,ilen,iamode,ierror)
```

path (Input) Character. The name of the file.

ilen (Input) INTEGER(4). The length of the *path* string.

iamode (Input) INTEGER(4). One or more of the following:

0	Checks for existence of the file.
1[1]	Checks for execute permission.
2	Checks for write access.
4	Checks for read access.
6	Checks for read/write access.

[1]Linux* only

ierror (Output) INTEGER(4). The error status.

If access is permitted, the result value is zero; otherwise, an error code. Possible error codes are:

- -1: A bad parameter was passed.
- ENOENT: The named directory does not exist.
- EACCES: Access requested was denied.

On Windows* systems, if the name given is a directory name, the function only checks for existence. All directories have read/write access on Windows systems.

PXFALARM

POSIX Subroutine: *Schedules an alarm.*

Module

USE IFPOSIX

Syntax

`CALL PXFALARM (iseconds,isecleft,ierror)`

iseconds (Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.

isecleft (Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered.

It is set to zero if there was no previously scheduled alarm signal.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFALARM subroutine arranges for a SIGALRM signal to be delivered to the process in seconds *iseconds*.

On Linux* systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

PXFCONST
IPXFCONST
PXFSIGACTION

PXFCALLSUBHANDLE

POSIX Subroutine: *Calls the associated subroutine.*

Module

USE IFPOSIX

Syntax

`CALL PXFCALLSUBHANDLE (jhandle2,ival,ierror)`

jhandle2	(Input) INTEGER(4). A handle to the subroutine.
ival	(Input) INTEGER(4). The argument to the subroutine.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine.

PXFGETSUBHANDLE should be used to obtain a subroutine handle.

NOTE
The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

See Also

PXFGETSUBHANDLE

PXFCFGETISPEED

POSIX Subroutine: *Returns the input baud rate from a termios structure. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFCFGETISPEED (jtermios,iospeed,ierror)`

jtermios	(Input) INTEGER(4). A handle of structure `termios`.
iospeed	(Output) INTEGER(4). The returned value of the input baud rate from the structure associated with handle *jtermios*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

NOTE
To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also

PXFSTRUCTCREATE

PXFCFSETISPEED

PXFCFGETOSPEED

POSIX Subroutine: *Returns the output baud rate from a termios structure.* *This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFCFGETOSPEED (jtermios,iospeed,ierror)`

jtermios	(Input) INTEGER(4). A handle of structure `termios`.
iospeed	(Output) INTEGER(4). The returned value of the output baud rate from the structure associated with handle *jtermios*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

NOTE
To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also

PXFSTRUCTCREATE
PXFCFSETOSPEED

PXFCFSETISPEED

POSIX Subroutine: *Sets the input baud rate in a termios structure.* *This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFCFSETISPEED (jtermios,ispeed,ierror)`

jtermios	(Input) INTEGER(4). A handle of structure `termios`.
ispeed	(Input) INTEGER(4). The value of the input baud rate for the structure associated with handle *jtermios*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

NOTE
To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also

PXFSTRUCTCREATE
PXFCFGETISPEED

PXFCFSETOSPEED

POSIX Subroutine: *Sets the output baud rate in a termios structure. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFCFSETOSPEED (jtermios,ispeed,ierror)`

jtermios	(Input) INTEGER(4). A handle of structure `termios`.
ispeed	(Input) INTEGER(4). The value of the output baud rate for the structure associated with handle *jtermios*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

NOTE
To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

See Also

PXFSTRUCTCREATE
PXFCFGETOSPEED

PXFCHDIR

POSIX Subroutine: *Changes the current working directory.*

Module

USE IFPOSIX

Syntax

`CALL PXFCHDIR (path,ilen,ierror)`

path	(Input) Character. The directory to be changed to.
ilen	(Input) INTEGER(4). The length of the *path* string.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

See Also

PXFMKDIR

PXFCHMOD

POSIX Subroutine: *Changes the ownership mode of the file.*

Module

USE IFPOSIX

Syntax

`CALL PXFCHMOD (path,ilen,imode,ierror)`

path	(Input) Character. The path to the file.
ilen	(Input) INTEGER(4). The length of the *path* string.
imode	(Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++ Installation in the `\include` directory under `sys\stat.h` for the values of *imode*. On Linux* systems, use octal file-access mode.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

> **NOTE**
> On Linux* systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

PXFCHOWN

POSIX Subroutine: *Changes the owner and group of a file. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFCHOWN (path,ilen,iowner,igroup,ierror)`

path	(Input) Character. The path to the file.
ilen	(Input) INTEGER(4). The length of the *path* string.
iowner	(Input) INTEGER(4). The owner UID.
igroup	(Input) INTEGER(4). The group GID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFCLEARENV

POSIX Subroutine: *Clears the process environment.*

Module

USE IFPOSIX

Syntax

```
CALL PXFCLEARENV (ierror)
```

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

After a call to PXFCLEARENV, no environment variables are defined.

PXFCLOSE

POSIX Subroutine: *Closes the file associated with the descriptor.*

Module

USE IFPOSIX

Syntax

```
CALL PXFCLOSE (fd,ierror)
```

fd (Input) INTEGER(4). A file descriptor.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

See Also

PXFOPEN

PXFCLOSEDIR

POSIX Subroutine: *Closes the directory stream.*

Module

USE IFPOSIX

Syntax

```
CALL PXFCLOSEDIR (idirid,ierror)
```

idirid (Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with *idirid*.

See Also

PXFOPENDIR

PXFCONST

POSIX Subroutine: *Returns the value associated with a constant.*

Module

USE IFPOSIX

Syntax

CALL PXFCONST (*constname*,*ival*,*ierror*)

constname	(Input) Character. The name of one of the following constants: • STDIN_UNIT • STDOUT_UNIT • STDERR_UNIT • EINVAL • ENONAME • ENOHANDLE • EARRAYLEN • ENOENT • ENOTDIR • EACCES The constants beginning with E signify various error values for the system variable `errno`.
ival	(Output) INTEGER(4). The returned value of the constant.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, it is set to -1.

For more information on these constants, see your Microsoft* Visual C++ documentation (Windows* systems) or the errno.h file (Linux* systems).

See Also

PXFISCONST

PXFCREAT

POSIX Subroutine: *Creates a new file or rewrites an existing file.*

Module

USE IFPOSIX

Syntax

CALL PXFCREAT (*path*,*ilen*,*imode*,*ifildes*,*ierror*)

path	(Input) Character. The pathname of the file.
ilen	(Input) INTEGER(4). The length of *path* string.
imode	(Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* systems, use octal file-access mode.
ifildes	(Output) INTEGER(4). The returned file descriptor.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFCTERMID

POSIX Subroutine: *Generates a terminal pathname.*
This routine is only available for Linux.

Module

USE IFPOSIX

Syntax

CALL PXFCTERMID (*s*,*ilen*,*ierror*)

s	(Output) Character. The returned pathname of the terminal.
ilen	(Output) INTEGER(4). The length of the returned value in the *s* string.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror*is set to zero; otherwise, an error code.

This subroutine returns a string that refers to the current controlling terminal for the current process.

PXFDUP, PXFDUP2

POSIX Subroutine: *Duplicates an existing file descriptor.*

Module

USE IFPOSIX

Syntax

CALL PXFDUP (*ifildes*,*ifid*,*ierror*)

CALL PXFDUP2 (*ifildes*,*ifildes2*,*ierror*)

ifildes	(Input) INTEGER(4). The file descriptor to duplicate.
ifid	(Output) INTEGER(4). The returned new duplicated file descriptor.
ifildes2	(Input) INTEGER(4). The number for the new file descriptor.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFDUP subroutine creates a second file descriptor for an opened file.

The PXFDUP2 subroutine copies the file descriptor associated with *ifildes*. Integer number *ifildes2* becomes associated with this new file descriptor, but the value of *ifildes2* is not changed.

PXFEGET

POSIX Subroutine: *Gets the value stored in an array element component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

CALL PXFE(type)GET (*jhandle*, *compname*,*index*,*value*,*ierror*)

```
CALL PXFE(type)GET (jhandle,compname,index,value,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFEINTGET
REAL	REAL(4)	PXFEREALGET
LGCL	LOGICAL(4)	PXFELGCLGET
STR	CHARACTER*(*)	PXFESTRGET
CHAR	CHARACTER(1)	PXFECHARGET
DBL	REAL(8)	PXFEDBLGET
INT8	INTEGER(8)	PXFEINT8GET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

index (Input) INTEGER(4). The index of the array element to get data for.

value (Output) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). Stores the value of the component (or field).

ilen (Output) INTEGER(4). This argument can only be used when *(type)* is STR (PXFESTRGET). Stores the length of the returned string.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFE(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)GET subroutines are used, the array element with index *index* is accessed (read from the component or field).

See Also

PXFE(type)SET
PXF(type)GET

PXFESET

POSIX Subroutine: *Sets the value of an array element component (or field) of a structure.*

Module

USE IFPOSIX

Syntax

```
CALL PXFE(type)SET (jhandle, compname,index,value,ierror)
```

```
CALL PXFE(type)SET (jhandle,compname,index,value,ilen,ierror) ! syntax when (type) is STR
```

(type) A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFEINTSET
REAL	REAL(4)	PXFEREALSET
LGCL	LOGICAL(4)	PXFELGCLSET
STR	CHARACTER*(*)	PXFESTRSET
CHAR	CHARACTER(1)	PXFECHARSET
DBL	REAL(8)	PXFEDBLSET
INT8	INTEGER(8)	PXFEINT8SET

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to write data to.

index (Input) INTEGER(4). The index of the array element to write data to.

value (Input) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). The value for the component (or field).

ilen (Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFESTRSET). The length of the string *value*.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFE(type)SET subroutines are similar to the PXF(type)SET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)SET subroutines are used, the array element with index *index* is accessed (written to the component or field).

See Also

PXFE(type)GET
PXF(type)SET

PXFEXECV

POSIX Subroutine: *Executes a new process by passing command-line arguments.*

Module

USE IFPOSIX

Syntax

```
CALL PXFEXECV (path,lenpath,argv,lenargv,iargc,ierror)
```

path	(Input) Character. The path to the new executable process.
lenpath	(Input) INTEGER(4). The length of *path* string.
argv	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
lenargv	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in *argv*.
iargc	(Input) INTEGER(4). The number of command-line arguments
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. If execution is successful, no return is made to the calling process.

See Also

PXFEXECVE
PXFEXECVP

PXFEXECVE

POSIX Subroutine: *Executes a new process by passing command-line arguments.*

Module

USE IFPOSIX

Syntax

`CALL PXFEXECVE (path,lenpath,argv,lenargv,iargc,env,lenenv,ienvc,ierror)`

path	(Input) Character. The path to the new executable process.
lenpath	(Input) INTEGER(4). The length of *path* string.
argv	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
lenargv	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in *argv*.
iargc	(Input) INTEGER(4). The number of command-line arguments.
env	(Input) An array of character strings. Contains the environment settings for the new process.
lenenv	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in *env*.
ienvc	(Input) INTEGER(4). The number of environment settings in *env*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the *argv* array and environment settings specified in the *env* array.

See Also

PXFEXECV
PXFEXECVP

PXFEXECVP

POSIX Subroutine: *Executes a new process by passing command-line arguments.*

Module

USE IFPOSIX

Syntax

CALL PXFEXECVP (*file*,*lenfile*,*argv*,*lenargv*,*iargc*,*ierror*)

file	(Input) Character. The filename of the new executable process.
lenfile	(Input) INTEGER(4). The length of *file* string.
argv	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
lenargv	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in *argv*.
iargc	(Input) INTEGER(4). The number of command-line arguments.
ierror	(Input) Character. The filename of the new executable process.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECVP subroutine executes a new executable process(file) by passing command-line arguments specified in the*argv* array. It uses the PATH environment variable to find the file to execute.

See Also

PXFEXECV
PXFEXECVE

PXFEXIT, PXFFASTEXIT

POSIX Subroutine: *Exits from a process.*

Module

USE IFPOSIX

Syntax

CALL PXFEXIT (*istatus*)

CALL PXFFASTEXIT (*istatus*)

istatus	(Input) INTEGER(4). The exit value.

The PXFEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions `atexit` and `onexit`, and flushes all file buffers before terminating the process. The *istatus* value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing `atexit` or `onexit`, and without flushing stream buffers.

Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
   print *," the child process will be born"
   call PXFFORK(IPID, IERROR)
   call PXFGETPID(IPID_RET,IERROR)
   if(IPID.EQ.0) then
     print *," I am a child process"
     print *," My child's pid is", IPID_RET
     call PXFGETPPID(IPID_RET,IERROR)
     print *," The pid of my parent is",IPID_RET
     print *," Now I have exited with code 0xABCD"
     call PXFEXIT(Z'ABCD')
   else
     print *," I am a parent process"
     print *," My parent pid is ", IPID_RET
     print *," I am creating the process with pid", IPID
     print *," Now I am waiting for the end of the child process"
     call PXFWAIT(ISTAT, IPID_RET, IERROR)
     print *," The child with pid ", IPID_RET," has exited"
     if( PXFWIFEXITED(ISTAT) ) then
       print *, " The child exited normally"
       istat_ret = IPXFWEXITSTATUS(ISTAT)
       print 10," The low byte of the child exit code is", istat_ret
     end if
   end if
10 FORMAT (A,Z)
end program
```

PXFFCNTL

POSIX Subroutine: *Manipulates an open file descriptor. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFFCNTL (*ifildes*,*icmd*,*iargin*,*iargout*,*ierror*)

ifildes	(Input) INTEGER(4). A file descriptor.
icmd	(Input) INTEGER(4). Defines an action for the file descriptor.
iargin	(Input; output) INTEGER(4). Interpretation of this argument depends on the value of *icmd*.
iargout	(Output) INTEGER(4). Interpretation of this argument depends on the value of *icmd*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in *icmd*, can be obtained by using the values of predefined macros in C header fcntl.h, or by using PXFCONST or IPXFCONST with one of the following constant names:

Constant	Action
F_DUPFD	Returns into *iargout* the lowest available unopened file descriptor greater than or equal to *iargin*. The new file descriptor refers to the same open file as *ifildes* and shares any locks. The system flag FD_CLOEXEC for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.
F_GETFD	Returns into *iargout* the value of system flag FD_CLOEXEC associated with *ifildes*. In this case, *iargin* is ignored.
F_SETFD	Sets or clears the system flag FD_CLOEXEC for file descriptor *ifildes*. The PXFEXEC family of functions will close all file descriptors with the FD_CLOEXEC flag set. The value for FD_CLOEXEC is obtained from argument *iargin*.
F_GETFL	Returns the file status flags for file descriptor *ifildes*. Unlike F_GETFD, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for PXFCONST or IPXFCONST, can be returned: • O_APPEND - Specifies the file is opened in append mode. • O_NONBLOCK - Specifies when the file is opened, it does not block waiting for data to become available. • O_RDONLY - Specifies the file is opened for reading only. • O_RDWR - Specifies the file is opened for both reading and writing. • O_WRONLY - Specifies the file is opened for writing only.
F_SETFL	Sets the file status flags from *iargin* for file descriptor *ifildes*. Only O_APPEND or O_NONBLOCK flags can be modified. In this case, *iargout* is ignored.
F_GETLK	Gets information about a lock. Argument *iargin* must be a handle of structure `flock`. This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle *iargin*. If there are no locks in place that would prevent the lock from being locked, field l_type in the structure is set to the value of the constant with symbolic name F_UNLCK.

Constant	Action
F_SETLK	Sets or clears a lock. Argument *iargin* must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field l_type. If the lock is busy, an error is returned.
F_SETLKW	Sets or clears a lock, but causes the process to wait if the lock is busy. Argument *iargin* must be a handle of structure `flock`. The lock is set or cleared according to the value of structure field l_type. If the lock is busy, PXFCNTL waits for an unlock.

NOTE
To get a handle for an instance of the `flock` structure, use PXFSTRUCTCREATE with the string 'flock' for the structure name.

PXFCONST

PXFFDOPEN
POSIX Subroutine: *Opens an external unit.*

Module
USE IFPOSIX

Syntax
`CALL PXFFDOPEN (ifildes,iunit,access,ierror)`

ifildes (Input) INTEGER(4). The file descriptor of the opened file.

iunit (Input) INTEGER(4). The Fortran logical unit to connect to file descriptor *ifildes*.

access (Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

Keyword	Possible Values	Description	Default
'NEWLINE'	'YES' or 'NO'	I/O type	'YES'
'BLANK'	'NULL' or 'ZERO'	Interpretation of blanks	'NULL'
'STATUS'	'OLD', 'SCRATCH', or 'UNKNOWN'	File status at open	'UNKNOWN'

Keyword	Possible Values	Description	Default
'FORM'	'FORMATTED' or 'UNFORMATTED'	Format type	'FORMATTED'

Keywords should be separated from their values by the equals ('=') character; for example:

```
call PXFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN',
IERROR)
```

ierror (Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by *iunit* to a file descriptor *ifildes*. If unit is already connected to a file, the file should be closed before using PXFFDOPEN.

NOTE
On Windows* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

See Also
PXFPOSIXIO

PXFFFLUSH
POSIX Subroutine: *Flushes a file directly to disk.*

Module
USE IFPOSIX

Syntax
`CALL PXFFFLUSH (lunit,ierror)`

lunit (Input) INTEGER(4). A Fortran logical unit.

ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFFLUSH subroutine writes any buffered output to the file connected to unit *lunit*.

PXFFGETC
POSIX Subroutine: *Reads a character from a file.*

Module
USE IFPOSIX

Syntax
`CALL PXFFGETC (lunit,char,ierror)`

lunit	(Input) INTEGER(4). A Fortran logical unit.
char	(Input) Character. The character to be read.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFGETC subroutine reads a character from a file connected to unit *lunit*.

See Also
PXFFPUTC

PXFFILENO
POSIX Subroutine: *Returns the file descriptor associated with a specified unit.*

Module
USE IFPOSIX

Syntax
```
CALL PXFFILENO (lunit,fd,ierror)
```

lunit	(Input) INTEGER(4). A Fortran logical unit.
fd	(Output) INTEGER(4). The returned file descriptor.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. Possible error codes are:

- EINVAL: *lunit* is not an open unit.
- EBADF: *lunit* is not connected with a file descriptor.

The PXFFILENO subroutine returns in *fd* the file descriptor associated with *lunit*.

NOTE
On Windows* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

NOTE
The file-descriptor used by POSIX is not the same as the corresponding file handle used by Windows, so it does not have the same value.

PXFPOSIXIO

PXFFORK
POSIX Subroutine: *Creates a child process that differs from the parent process only in its PID. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFFORK (*ipid*,*ierror*)

ipid	(Output) INTEGER(4). The returned PID of the new child process.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent's thread of execution, and a zero is returned in the child's thread of execution. Otherwise, a -1 is returned in the parent's context and no child process is created.

Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *," the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET,IERROR)
  if(IPID.EQ.0) then
     print *," I am a child process"
     print *," My child's pid is", IPID_RET
     call PXFGETPPID(IPID_RET,IERROR)
     print *," The pid of my parent is",IPID_RET
     print *," Now I have exited with code 0xABCD"
     call PXFEXIT(Z'ABCD')
  else
     print *," I am a parent process"
     print *," My parent pid is ", IPID_RET
     print *," I am creating the process with pid", IPID
     print *," Now I am waiting for the end of the child process"
     call PXFWAIT(ISTAT, IPID_RET, IERROR)
     print *," The child with pid ", IPID_RET," has exited"
     if( PXFWIFEXITED(ISTAT) ) then
       print *, " The child exited normally"
       istat_ret = IPXFWEXITSTATUS(ISTAT)
       print 10," The low byte of the child exit code is", istat_ret
     end if
  end if
10 FORMAT (A,Z)
end program
```

IPXWEXITSTATUS

PXFFPATHCONF

POSIX Subroutine: *Gets the value for a configuration option of an opened file.*

Module

USE IFPOSIX

Syntax

```
CALL PXFFPATHCONF (ifildes,name,ival,ierror)
```

ifildes	(Input) INTEGER(4). The file descriptor of the opened file.
name	(Input) INTEGER(4). The configurable option.
ival	(Output) INTEGER(4). The value of the configurable option.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor *ifildes*.

The configuration option, defined in *name*, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

Constant	Action
_PC_LINK_MAX	Returns the maximum number of links to the file. If *ifildes* refers to a directory, then the value applies to the whole directory.
_PC_MAX_CANON[1]	Returns the maximum length of a formatted input line; the file descriptor *ifildes* must refer to a terminal.
_PC_MAX_INPUT[1]	Returns the maximum length of an input line; the file descriptor *ifildes* must refer to a terminal.
_PC_NAME_MAX	Returns the maximum length of a filename in *ifildes* that the process is allowed to create.
_PC_PATH_MAX	Returns the maximum length of a relative pathname when *ifildes* is the current working directory.
_PC_PIPE_BUF	Returns the size of the pipe buffer; the file descriptor *ifildes* must refer to a pipe or FIFO.
_PC_CHOWN_RESTRICTED[1]	Returns nonzero if PXFCHOWN may not be used on this file. If *ifildes* refers to a directory, then this applies to all files in that directory.
_PC_NO_TRUNC[1]	Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.
_PC_VDISABLE[1]	Returns nonzero if special character processing can be disabled; the file descriptor *ifildes* must refer to a terminal.

[1]Linux

On Linux* systems, the corresponding macros are defined in <unistd.h>. The values for *name* can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in <unistd.h>. The following table shows the corresponding macro names for the above constants:

Constant	Corresponding Macro
_PC_LINK_MAX	_POSIX_LINK_MAX
_PC_MAX_CANON	_POSIX_MAX_CANON
_PC_MAX_INPUT	_POSIX_MAX_INPUT
_PC_NAME_MAX	_POSIX_NAME_MAX
_PC_PATH_MAX	_POSIX_PATH_MAX
_PC_PIPE_BUF	_POSIX_PIPE_BUF
_PC_CHOWN_RESTRICTED	_POSIX_CHOWN_RESTRICTED
_PC_NO_TRUNC	_POSIX_NO_TRUNC
_PC_VDISABLE	_POSIX_VDISABLE

PXFPATHCONF

PXFFPUTC
POSIX Subroutine: *Writes a character to a file.*

Module
USE IFPOSIX

Syntax
```
CALL PXFFPUTC (lunit,char,ierror)
```

lunit	(Input) INTEGER(4). A Fortran logical unit.
char	(Input) Character. The character to be written.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit *lunit*.

See Also
PXFFGETC

PXFFSEEK
POSIX Subroutine: *Modifies a file position.*

Module
USE IFPOSIX

Syntax
```
CALL PXFFSEEK (lunit,ioffset,iwhence,ierror)
```

lunit	(Input) INTEGER(4). A Fortran logical unit.
ioffset	(Input) INTEGER(4). The number of bytes away from *iwhence* to place the pointer.
iwhence	(Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in `stdio.h`):

SEEK_SET = 0	Offset from the beginning of the file.
SEEK_CUR = 1	Offset from the current position of the file pointer.
SEEK_END = 2	Offset from the end of the file.

ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. Possible error codes are:

- EINVAL: No file is connected to *lunit*, *iwhence* is not a proper value, or the resulting offset is invalid.
- ESPIPE: *lunit* is a pipe or FIFO.
- EEND: The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit *lunit*.

PXFFSTAT

POSIX Subroutine: *Gets a file's status information.*

Module

USE IFPOSIX

Syntax

`CALL PXFFSTAT (ifildes,jstat,ierror)`

ifildes	(Input) INTEGER(4). The file descriptor for an opened file.
jstat	(Input) INTEGER(4). A handle of structure `stat`.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with *ifildes* into the structure associated with handle *jstat*.

> **NOTE**
> To get a handle for an instance of the `stat` structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

See Also

PXFSTRUCTCREATE

PXFFTELL

POSIX Subroutine: *Returns the relative position in bytes from the beginning of the file.*

Module

USE IFPOSIX

Syntax

CALL PXFFTELL (*lunit*,*ioffset*,*ierror*)

lunit	(Input) INTEGER(4). A Fortran logical unit.
ioffset	(Output) INTEGER(4). The returned relative position in bytes from the beginning of the file.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFGETARG

POSIX Subroutine: *Gets the specified command-line argument.*

Module

USE IFPOSIX

Syntax

CALL PXFGETARG (*argnum*,*str*,*istr*,*ierror*)

argnum	(Input) INTEGER(4). The number of the command-line argument.
str	(Output) Character. The returned string value.
istr	(Output) INTEGER(4). The length of the returned string; it is zero if an error occurs.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETARG subroutine places the command-line argument with number *argnum* into character string *str*. If *argnum* is equal to zero, the value of the argument returned is the command name of the executable file.

See Also

IPXFARGC

PXFGETC

POSIX Subroutine: *Reads a character from standard input unit 5.*

Module

USE IFPOSIX

Syntax

CALL PXFGETC (*nextcar*,*ierror*)

nextcar	(Output) Character. The returned character that was read.

ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

See Also

PXFPUTC

PXFGETCWD

POSIX Subroutine: *Returns the path of the current working directory.*

Module

USE IFPOSIX

Syntax

CALL PXFGETCWD (*buf*,*ilen*,*ierror*)

buf	(Output) Character. The returned pathname of the current working directory.
ilen	(Output) INTEGER(4). The length of the returned pathname.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of *buf* is insufficient.

PXFGETEGID

POSIX Subroutine: *Gets the effective group ID of the current process. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFGETEGID (*iegid*,*ierror*)

iegid	(Output) INTEGER(4). The returned effective group ID.
ierror	(Output) INTEGER(4). The error status.

Description

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

PXFGETENV

POSIX Subroutine: *Gets the setting of an environment variable.*

Module

USE IFPOSIX

Syntax

```
CALL PXFGETENV (name,lenname,value,lenval,ierror)
```

name	(Input) Character. The name of the environment variable.
lenname	(Input) INTEGER(4). The length of *name*.
value	(Output) Character. The returned value of the environment variable.
lenval	(Output) INTEGER(4). The returned length of *value*. If an error occurs, it returns zero.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

See Also

PXFSETENV

PXFGETEUID

POSIX Subroutine: *Gets the effective user ID of the current process. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

```
CALL PXFGETEUID (ieuid,ierror)
```

ieuid	(Output) INTEGER(4). The returned effective user ID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

PXFGETGID

POSIX Subroutine: *Gets the real group ID of the current process. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

```
CALL PXFGETGID (igid,ierror)
```

igid	(Output) INTEGER(4). The returned real group ID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

Example

See the example in PXFGETGROUPS

See Also

PXFSETGID

PXFGETGRGID

POSIX Subroutine: *Gets group information for the specified GID. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFGETGRGID (jgid,jgroup,ierror)`

jgid	(Input) INTEGER(4). The group ID to retrieve information about.
jgroup	(Input) INTEGER(4). A handle of structure `group`.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETGRGID subroutine stores the group information from `/etc/group` for the entry that matches the group GID *jgid* in the structure associated with handle *jgroup*.

> **NOTE**
> To get a handle for an instance of the `group`structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

Example

See the example in PXFGETGROUPS

See Also

PXFSTRUCTCREATE

PXFGETGRNAM

POSIX Subroutine: *Gets group information for the named group. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

`CALL PXFGETGRNAM (name,ilen,jgroup,ierror)`

name	(Input) Character. The name of the group to retrieve information about.
ilen	(Input) INTEGER(4). The length of the *name* string.
jgroup	(Input) INTEGER(4). A handle of structure group.

ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETGRNAM subroutine stores the group information from /etc/group for the entry that matches the group name name in the structure associated with handle *jgroup*.

> **NOTE**
> To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

See Also

PXFSTRUCTCREATE

PXFGETGROUPS

POSIX Subroutine: *Gets supplementary group IDs.*
This routine is only available for Linux.

Module

USE IFPOSIX

Syntax

CALL PXFGETGROUPS (*igidsetsize*,*igrouplist*,*ngroups*,*ierror*)

igidsetsize	(Input) INTEGER(4). The number of elements in the *igrouplist* array.
igrouplist	(Output) INTEGER(4). The array that has the returned supplementary group IDs.
ngroups	(Output) INTEGER(4). The total number of supplementary group IDs for the process.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETGROUPS subroutine returns, up to size *igidsetsize*, the supplementary group IDs in array *igrouplist*. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

Example

```
program test5
  use ifposix
  implicit none
  integer(4) number_of_groups, ierror, isize,i, igid
  integer(4),allocatable,dimension(:):: igrouplist
  integer(JHANDLE_SIZE) jgroup

  ! Get total number of groups in system
  ! call PXFGETGROUPS with 0
  call PXFGETGROUPS(0, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) STOP 'Error: first call of PXFGETGROUPS fails'
  print *," The number of groups in system ", number_of_groups
```

```
  ! Get Group IDs
  isize = number_of_groups
  ALLOCATE( igrouplist(isize))
  call PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) then
     DEALLOCATE(igrouplist)
     STOP 'Error: first call of PXFGETGROUPS fails'
  end if

  print *," Create an instance for structure 'group' "
  call PXFSTRUCTCREATE("group",jgroup, ierror)
  if(ierror.NE.0) then
     DEALLOCATE(igrouplist)
     STOP 'Error: PXFSTRUCTCREATE failed to create an instance of group'
  end if

  do i=1,  number_of_groups
     call PXFGETGRGID( igrouplist(i), jgroup, ierror)
     if(ierror.NE.0) then
       DEALLOCATE(igrouplist)
       call PXFSTRUCTFREE(jgroup, ierror)
       print *,'Error: PXFGETGRGID failed for i=',i," gid=", igrouplist(i)
       STOP 'Abnormal termination'
     end if
     call PRINT_GROUP_INFO(jgroup)
  end do

  call PXFGETGID(igid,ierror)
  if(ierror.NE.0) then
     DEALLOCATE(igrouplist)
     call PXFSTRUCTFREE(jgroup, ierror)
     print *,'Error: PXFGETGID failed'
     STOP 'Abnormal termination'
  end if
  call PXFGETGRGID( igid, jgroup, ierror)
  if(ierror.NE.0) then
     DEALLOCATE(igrouplist)
     call PXFSTRUCTFREE(jgroup, ierror)
     print *,"Error: PXFGETGRGID failed for  gid=", igid
     STOP 'Abnormal termination'
  end if

  call PRINT_GROUP_INFO(jgroup)
  DEALLOCATE(igrouplist)
  call PXFSTRUCTFREE(jgroup, ierror)
  print *," Program will normal terminated"
  call PXFEXIT(0)
end
```

PXFGETLOGIN

POSIX Subroutine: *Gets the name of the user.*

Module

USE IFPOSIX

Syntax

CALL PXFGETLOGIN (*s*,*ilen*,*ierror*)

s	(Output) Character. The returned user name.
ilen	(Output) INTEGER(4). The length of the string stored in *s*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFGETPGRP

POSIX Subroutine: *Gets the process group ID of the calling process. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFGETPGRP (*ipgrp*,*ierror*)

ipgrp	(Output) INTEGER(4). The returned process group ID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Each process group is a member of a session and each process is a member of the session in which its process group is a member.

PXFGETPID

POSIX Subroutine: *Gets the process ID of the calling process.*

Module

USE IFPOSIX

Syntax

CALL PXFGETPID (*ipid*,*ierror*)

ipid	(Output) INTEGER(4). The returned process ID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *," the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET,IERROR)
  if(IPID.EQ.0) then
     print *," I am a child process"
     print *," My child's pid is", IPID_RET
     call PXFGETPPID(IPID_RET,IERROR)
     print *," The pid of my parent is",IPID_RET
     print *," Now I have exited with code 0xABCD"
```

```
    call PXFEXIT(Z'ABCD')
  else
    print *," I am a parent process"
    print *," My parent pid is ", IPID_RET
    print *," I am creating the process with pid", IPID
    print *," Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The child with pid ", IPID_RET," has exited"
    if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
    end if
  end if
10 FORMAT (A,Z)
end program
```

PXFGETPPID

POSIX Subroutine: *Gets the process ID of the parent of the calling process.*

Module

USE IFPOSIX

Syntax

CALL PXFGETPPID (*ippid*,*ierror*)

ippid	(Output) INTEGER(4). The returned process ID.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *," the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET,IERROR)
  if(IPID.EQ.0) then
    print *," I am a child process"
    print *," My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET,IERROR)
    print *," The pid of my parent is",IPID_RET
    print *," Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
  else
    print *," I am a parent process"
    print *," My parent pid is ", IPID_RET
    print *," I am creating the process with pid", IPID
    print *," Now I am waiting for the end of the child process"

PXFGETPWNAM

POSIX Subroutine: *Gets password information for a specified name. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFGETPWNAM (*name*,*ilen*,*jpasswd*,*ierror*)

name	(Input) Character. The login name of the user to retrieve information about. For example, a login name might be "jsmith", while the actual name is "John Smith".
ilen	(Input) INTEGER(4). The length of the *name* string.
jpasswd	(Input) INTEGER(4). A handle of structure *compnam*.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETPWNAM subroutine stores the user information from /etc/passwd for the entry that matches the user name *name* in the structure associated with handle *jpasswd*.

> **NOTE**
> To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

PXFSTRUCTCREATE

PXFGETPWUID

POSIX Subroutine: *Gets password information for a specified UID. This routine is only available for Linux.*

Module

USE IFPOSIX

Syntax

CALL PXFGETPWUID (*iuid*,*jpasswd*,*ierror*)

iuid	(Input) INTEGER(4). The user ID to retrieve information about.
jpasswd	(Output) INTEGER(4). A handle of structure compnam.

ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETPWUID subroutine stores the user information from /etc/passwd for the entry that matches the user ID *iuid* in the structure associated with handle *jpasswd*.

NOTE
To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

PXFSTRUCTCREATE

PXFGETSUBHANDLE
POSIX Subroutine: *Returns a handle for a subroutine.*

Module
USE IFPOSIX

Syntax
CALL PXFGETSUBHANDLE (*sub*,*jhandle1*,*ierror*)

sub	(Input) The Fortran subroutine to get a handle for.
jhandle1	(Output) INTEGER(4). The returned handle for the subroutine.
ierror	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

NOTE
The argument *sub* cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

PXFGETUID
